This is the buttress behind which officialdom shelters itself. The Board of Trade requires that death and disaster shall first take place before they will take the necessary steps to eliminate colour-blind and defective far-sighted subjects from occupying responsible positions on the decks and bridges of our merchant vessels. Mr. Bryce, instead of perusing the reports he alludes to for months might do so for years—for a lifetime in fact—and not find a single case in which the court finds that a vessel has been lost through the defective vision of some member of its or another vessel's crew. But, if Mr. Bryce will deign to peruse the reports in question with an impartial mind, first dismissing the official view that the risk from colour blindness and defective sight is a mere bogey, raised by the medical profession and believed in by the press, he will have but little difficulty in learning that many collisions occurring at sea by night are of an altogether unaccountable character. The atmosphere may be clear, the respective look-outs alert, so that the approaching vessels are duly signalled and reported before the danger point is reached. In spite of this, collision occurs. Through what cause? The Board of Trade maintain the cause may be anything save and except colour blindness or defective sight. The preconceived official view on that visual defect quite precludes any suspicion that the disaster was due to such a factor. Common sense would say, why in such cases is not the eyesight of the survivors of such a catastrophe tested? Why too in cases where there is a glaring contradiction on matters of fact respecting the position of converging vessels as manifested by their sidelights does not the court insist upon the eyesight of the witnesses being tested? If such steps were taken I venture to assert that many an inexplicable disaster would be solved and many an apparent case of wilful perjury would be explained.

I challenge Mr. Bryce and the Board of Trade to point to one single case out of the many thousands that have occurred where, after collision, the Board have ordered an examination of the eyesight of the surviving officers and look-outs, and I submit that Mr. Bryce's misleading—not to use a stronger adjective—reply was not of the kind to be expected from the responsible Minister of a great public department. Rightly or wrongly, I felt at the time that his reply was an invasion of the positive evidence laid before him, and was

directed towards screening the permanent officials from the charge of apathy and negligence. Unquestionably it deceived, with a few notable exceptions, the public press, and not for the first time was the public gulled into a false feeling of security. Little did I think such a striking proof of their negligence and incapacity would so soon be forthcoming.

It might have been thought that the somewhat inexplicable cause of the *Elbe* and *Crathie* disaster would have suggested to the Board of Trade officials the advisability of testing the eyesight and colour sense of the *Crathie's* look-out men. Apart, however, from the utter improbability of themselves deeming it advisable to sift this phase of the question, they even refused to do so when asked.

Thinking that in such a lamentable catastrophe as this no stone should be left unturned in the endeavour to trace to its true source the cause of the disaster, I wrote to the Board of Trade while their inquiry was pending, suggesting the desirability of examining the eyesight and colour sense of such of the *Crathie's* crew as were on deck at the time of the casualty.

In response to my letter I received from the Board of Trade an autograph communication, of which the following is a copy:

Board of Trade, Whitehall Gardens, S.W.

May 24th, 1895.

DEAR SIR.—I am directed by Mr. Bryce to acknowledge receipt of your letter of yesterday's date, and to state in reply that the question of the powers of vision will be carefully borne in mind in the Board of Trade inquiry into the cause of the collision between the *Elbe* and the *Crathie*.—Yours faithfully,

(Signed) GARNHAM ROPER.

A perusal of the above letter clearly conveys the impression that the Board of Trade intended—or, rather, stated their intention—to examine the eyesight of the *Crathie's* look-outs. The inquiry, however, was duly held as announced, but the question of defective sight not being mentioned in the full reports appearing in the *Times*, I wrote again to the Board of Trade, asking for a definite statement of fact as to whether these look-outs had actually been examined or no. In reply I was honoured with the following letter:

Board of Trade Marine Department, 7, Whitehall Gardens.

June 24th, 1895.

SIR.—With reference to your letter of the 19th inst., asking whether the look-outs of the *Crathie* were examined as to their eyesight, and where you can obtain a copy of the evidence taken, I am directed by the Board of Trade to state that the witnesses were not examined as to their eyesight, and that the evidence of both sides showed that colour blindness had nothing to do with the cause of the collision.—I am, Sir, your obedient servant,

(Signed) INGRAM B. WALKER.

Colour blindness or defective vision may or may not have had something to do with the disaster; but I maintain most emphatically that, considering the awful nature of the catastrophe and the unsatisfactory nature of the evidence forthcoming, the Board of Trade should have tested the eyesight of the *Crathie's* look-outs, and that in the face of these letters their failure to do so constitutes a most serious dereliction of duty, and one which imperatively calls for Parliamentary action.

So much for Board of Trade persistency in escaping by any and every loophole from admitting that defective sight or colour vision may be productive of maritime disaster.

A few words now on the subject of the Board of Trade's present regulations as to the proper time when the tests for colour blindness or defective sight should be applied. Instead of being enforced before the articles of indentures are signed—and this is the proper moment—the tests only become compulsory on a candidate applying for a certificate of mate. They are thus only applied after a tedious apprenticeship has been completed, and when the candidate has, by following the sea, unfitted himself for success in other walks of life. What are the rejected ones to do? Stay on shore and starve, or go to sea? The public have an idea that the Board of Trade tests eliminate the visually imperfect from our mercantile marine. But is that so? The following letter shows that the only course open to the rejected is to go to sea, colour blindness or defective sight notwithstanding.

It is the letter of a hardworking sealer, and industrious young fellow, a lifelong total abstainer, one who would under kinder circumstances have become an ornament to his profession. Falling after being rejected for colour blindness to

get a berth on shore, even at the paltry pittance of £1 per week, he was literally compelled to go to sea as an A.B. at a wage of £3 10s. per month. But let him state his own case.

"I signed my indentures on December 28th, 1887, to Mr. S. J. Liverpool, for four years. I joined my ship at Cardiff, January 1st, 1888, and finished my term of apprenticeship. I was also nine months over my time in the same vessel as A.B. On arriving home I went to school to coach for second mate. I put in my papers October 14th, 1892 (Friday), and was told I was colour blind. At the advice of my late captain I took a short trip up the Mediterranean in a steamer belonging to Messrs. L. (the voyage occupying a month). Again my sight was tested and was failed in the 'greens,' but was told my sight in other colours was perfect. There was no hope for me to pass my exam., but at the same time there was nothing to prevent me going before the mast. I went away then in one of the Pacific Steam Navigation Company's Royal Mail Steamers, in which I have been seven voyages. During these voyages I have never had any complaints as to my ability to keep a proper look-out. This I did in a fast steamer for over two years. In conclusion, I may state that my only prospect now is to continue as A.B. for the rest of my days. (Signed) E.B.W."

For many years past we have told the Board of Trade that their adoption of imperfect tests and regulations has, by permitting the entry of colour-blind subjects into the service, constituted a serious double offence. By such laxity, not only have incompetent men been foisted upon the public as competent ones, but the inhuman procedure has been followed of granting certificates of competency which, on the introduction of reliable tests, would be rendered valueless to the possessor, and would consequently entail loss of occupation, or, in other words, ruin.

This constitutes a serious blot on the fair fame of our Government. The colour-blind officer has neither riches, influence, nor even a Parliamentary vote at his command; no redress is open to him: his only course is to quietly submit, without even an opportunity of protest, and he is consequently plunged into the depths of despair.

The present Government has a clean page before it. Humanity demands, and a sense of right dictates, that these poor men be not cast adrift. Their names and addresses are known to the Board of Trade. Let Government see that at the earliest opportunity shore berths in Government offices be offered to them, and thus, in some measure, they may be compensated for that loss of position and means of livelihood which, through no fault of their own, has unfortunately fallen to their lot.

If I am thought to be exaggerating the distress entailed, the recital of the following cases will carry conviction, where perhaps my mere statements would fail.

By the courtesy of Mr. J. Clark Hall, Registrar-General of Shipping and Seamen, I hold in my hands the returns of those men, failing to comply with the colour and eyesight tests, from September 1st, 1891, when the new tests came into force, to July 26th, 1895. The numbers are truly appalling. No fewer than 76 failed on account of colour blindness, and 80 for defective sight. Think for a few moments of what this means. Who can form the faintest conception of the depth of blank despair into which these poor fellows are plunged in an instant, victims of the crass ignorance, pride, and hardness of heart of gentlemen who, whatever they may be in private life, exhibit in their public capacity a callousness which cannot be surpassed, if paralleled, throughout the length and breadth of the land. I have seen men, strong in the pride of manhood, men who would face any danger, and who are a credit to any nation, utterly broken down on hearing that their position and livelihood—secure at one moment—are, through no fault of their own, swept away at the next.

I have already recorded the case of Captain Smith, who, after being at sea for twenty years, and in the possession of a Board of Trade's master's certificate, was accidentally found to be colour-blind, and was dismissed his ship. The ruin of his hopes and home—he was married and had three children—so passed upon his head that, though up to that

his health gradually gave way, and his death occurred in a little over twelve months after his dismissal.

A still more distressing illustration is to be found in the case of Captain F., who, in April, 1895, was discovered, also accidentally, to be colour-blind. A quotation from a letter received from the house-surgeon of the institution in which he was an inmate, in consequence of attempted suicide, will best describe his condition: "Early in this year the patient's certificate was endorsed 'colour blind,' in consequence of which he has been thrown out of employment. This has preyed upon his mind. He became sleepless and unsettled, and eventually tried to do away with himself by leaping into one of the docks. During his stay in hospital he was observed to be very melancholic, apparently taking no interest in his surroundings, and quite hopeless as to his future."

The bitter pathos of despair embodied in the above illustrations would be hard to parallel. Humanity and justice alike ask why the Board of Trade do not institute their tests so as to preclude a colour-blind or weak-sighted lad from embarking upon a sailor's life. The medical profession has long asked this question, the shipping and general press have long urged it; and, what is even more reflecting upon the criminal ineptitude of the Board of Trade, the Committee appointed by the Royal Society and paid out of the public funds for the express purpose of considering this very subject, made it one of their most important recommendations, if not the most important of all. Why should the Board of Trade seek costly advice and then not act upon it? How long will the British nation tamely submit to such a manifestation of wilful perversity? Their examiners can produce many such harrowing cases of a life of promise blasted as the above; still the evil is unremedied, although the means is so easily available.

There is, too, another aspect of the question. The sight examiners have to test candidates' knowledge of seamanship and navigation as well, and the new visual tests appropriate a great deal of time and entail much clerical work. The duties of the examiners are thus vastly increased. The work must be got through, however, and it is open to question if some section or other of the examination scheme does not suffer in consequence. On this ground alone, if on no other, a strong case is made out for expert examination. It is not the first time by a long way that the Board of Trade has been similarly indicted upon this same question. The matter is one of national importance, rather than one which calls for the intervention of the medical profession alone. What is to be done to bring the Board of Trade to its senses? It is of little use interviewing the President of the Board of Trade, if like Mr. Bryce he is content to allow the officials of his department to continue the time-honoured but criminal policy of refusing amendment. By such methods we may even do harm, for the press and the public are bound to pay more heed to his reply than to the statement of our case. What, then, is to be done to make the British nation insist that the Board of Trade shall adopt a humane, an enlightened, and a less criminally stupid policy on this important question?

Mr. Bickerton's paper was discussed by Dr. CALDWELL, Dr. FARQUHARSON, M.P., Dr. EDWIN GREEN, and the PRESIDENT (Mr. Henry Power). On the President's suggestion the following resolution was proposed by Dr. FARQUHARSON, and carried unanimously:

That the following points should be brought before the attention of Parliament:

1. Adequate tests should be compulsorily applied before a lad is apprenticed to the sea-life.
2. The Royal Society's recommendations should be applied in their entirety.
3. That officers already holding certificates, and now, by the institution of adequate tests, found colour blind, should have shore berths given them in Government offices.

EVERYONE who has visited the French capital knows how recklessly the Paris Jehu drives, but most people will probably be startled by a calculation made by the *Progres Medical*, according to which the number of persons killed or injured by omnibuses and other vehicles in a single year exceeds the number of victims of railway accidents in France in two years.

SECTION OF SURGERY.

Sir W. MACCORMAC, F.R.C.S., President.

SEQUEL TO THE CASE OF LATERAL ANASTOMOSIS BY MEANS OF MURPHY'S BUTTON.

PUBLISHED IN THE "BRITISH MEDICAL JOURNAL," OF APRIL 20TH, 1896.

By CHARLES A. MORTON, F.R.C.S.,

Surgeon to the Bristol General Hospital; Demonstrator of Anatomy, University College, Bristol.

BEFORE describing the junction made by the button and the condition of the diseased portions of bowel, I will very briefly give an abstract of the case as reported in the *BRITISH MEDICAL JOURNAL*. The patient was aged 27, and suffered from intestinal obstruction due to a malignant stricture at the junction of the cæcum and ascending colon, for which the cæcum was opened with complete relief. Three months later obstruction again set in—presumably from blockage by growth further back—and I then made a lateral anastomosis between the distended small intestine and the sigmoid flexure by means of Murphy's button, with complete relief

CM, Cæcum almost filled up by new growth, which also surrounds the ileum at its junction with the cæcum; AA, the old artificial anus; A, the anastomosis; IL, the ileum coming from the stomach to the anastomosis; ILA, the ileum going from the anastomosis to the cæcum; C, colon; G, the new growth around the anastomosis; R, the greatly-dilated rectum; B, the button.

from the symptoms, but the abdominal distension did not wholly subside as it did after the colotomy, and occasionally a visible coil could be seen contracting, followed by a loud gurgle in the region of the anastomosis. Towards the end of April he had become very emaciated and feeble, and was attacked with troublesome diarrhoea. The growth in the cæcum invaded the abdominal wall around the colotomy opening, and the inguinal glands became affected, and the growth could be felt under the scar of the incision for the anastomosis. He died on April 24th, three months after the anastomosis operation.

Post-mortem Examination.—All the intestines in the lower half of the abdomen were infiltrated on their peritoneal aspect with new growth and were matted together and adherent to the abdominal wall. This was the condition at the anastomosis. The button used to join the intestine has a diameter of 1 inch, and the opening, three months after operation, had a diameter of $\frac{3}{4}$ of an inch, showing only $\frac{1}{4}$ of an inch contraction, even where surrounded by new growth, which was constricting the bowel. A fine dark ring in the mucous membrane marked the junction of that structure. The new growth around the anastomosis was in the outer wall of the bowel, and only one minute nodule

had invaded the interior. I found the junction had been made 4 feet above the ileo-cæcal valve.

Of the two portions of ileum which opened into the sigmoid flexure at the anastomosis, the one which was the continuation of the bowel from the stomach had an opening $\frac{1}{2}$ inch in diameter, the one which was continued on to the cæcum of only $\frac{1}{4}$ inch. The former was considerably dilated and thickened for some feet above the anastomosis; the latter was even more so, but the last foot before joining the cæcum was much narrowed by a surrounding mass of growth, continuous with that which occupied the position of the cæcum. The cavity of the cæcum was filled up by growth with the exception of a sloughing excavation in its interior. The button lay in another cavity in this mass of malignant growth, just at the junction of ileum and cæcum, but all trace of the original opening of the ileum into the cæcum was lost in the mass of growth. The track which led to the button from the anastomosis had become narrowed by surrounding growth, so that it could not return into the ileum, and between it and the old colotomy opening was a mass of new growth which was sloughing, so that a communication had been established between the cavity where the button lay and the colotomy opening; and had the destruction of the new growth here advanced further the button would have appeared at the old artificial anus. The button had slipped back into the diseased portion of ileum, and been carried by peristalsis—or antiperistalsis, as Senn calls it—as far as it could go, that is, to the point where the ileo-cæcal valve was obliterated by new growth. It was this blockage which no doubt caused the second attack of obstruction. The growth originally situated at the junction of the cæcum and ascending colon, spread backwards and invaded the ileo-cæcal junction, and then the whole cæcum. In the sigmoid flexure immediately below the anastomosis the gut was constricted to a diameter of $\frac{1}{2}$ inch from new growth in its outer wall. The colon above this as far back as the obstructing growth in the cæcum and its junction with the ascending colon was much dilated and thickened, and for some inches above the anastomosis was honeycombed by ulceration. There was only a little liquid faecal matter in this portion of the bowel. The portion of the sigmoid flexure below the anastomosis opening and the upper part of the rectum were not dilated much; they were bound down by growth, but the lower end of the rectum was enormously dilated. The button was in perfect working order. The sloughs were still present, clinging to the silk threads, in the groove of the instrument.

The contraction then of the opening made by the button was only $\frac{1}{4}$ inch in three months, with constricting new growth around it. One cannot help regretting very much the presence of this growth, as it makes it impossible to say with absolute certainty whether the $\frac{1}{4}$ inch contraction was cicatricial or due to the growth, but it seems to me that one would have expected as much or more contraction from the presence of the growth *per se*. The possibility of contraction of the orifice taking place after junction by means of Murphy's button was one of the objections raised to its use when it was first introduced. In Keen's case,¹ one in which the cut end of the ileum was joined to the side of the sigmoid flexure, and the junction was examined forty-seven days later, the button measured 1 inch in diameter and the opening $\frac{1}{2}$ inch, showing contraction to half of the original diameter. The entire colon at the point where the anastomosis was made was narrowed to 1 inch in diameter, the diameter of the colon towards the splenic flexure being 1 $\frac{1}{2}$ inch, and at the rectal end 2 $\frac{1}{2}$ inches. After reading the report of the case, I cannot accept Murphy's explanation of this—that the contraction of the opening was due to the contraction of the previously distended bowel—as there is no evidence of previous distension. The anastomosis was made not for obstruction, but for the cure of artificial anus. It seems to me that the contraction both of the orifice and the lumen of the bowel at the seat of anastomosis must have been due to cicatricial contraction, but why such an amount of contraction should have taken place in this case in six weeks and only $\frac{1}{4}$ inch in my case in three months, I am at a loss to understand. Certainly there was a difference in the mode of junction. Keen's case was an end-to-side junction,

¹ *Annals of Surgery*, vol. xvii, p. 663, 1893.

whereas mine was a side-to-side, but one would, I think, expect to find a more contraction in the latter.

But I should not like Dr. Murphy to think that by referring to Dr. Keen's case I am trying to raise an objection to the use of the button on the ground that it causes stenosis; and had Dr. Murphy not been present I had intended quoting from his published writings* to show that judging by the clinical evidence stenosis after junction has been formed by the button, is exceedingly rare.

Why did the button pass into the diseased portion of intestine in my case instead of passing *per anam*? It has gone the wrong way in a few other cases. Mr. Mayo Robson records† a case in which the same junction which I effected was made, that is, a lateral one between the ileum and sigmoid flexure—and in his case also the button passed backwards into the caecum. Abbe mentioned at the New York Surgical Society‡ that in one case of union of intestine with the button it was found six weeks later to have fallen back into the loop of bowel on the proximal side of the union; and at the same meeting of the Society three cases were reported of gastro-enterostomy in which the button fell back into the stomach. It has been suggested that this difficulty may be got rid of by always placing the heaviest half of the button in the portion of bowel along which it is desired it may pass. This would no doubt answer if the patient always remained in such a position after the operation that the button lay evenly balanced as in scales, but this can only happen by the merest chance. Whether the button pass the right way or the wrong in cases of lateral approximation (and the difficulty does not occur in simple end-to-end junction of intestine) will depend on how the patient lies after the operation, having regard to the position of the coils when the abdomen is closed after the anastomosis. When one coil is fixed, as in the case of the sigmoid, this would not materially alter with peristalsis. But we cannot keep the patient lying for weeks in one position, and if it is not constant the button may just happen to become detached when the right position is not assumed. In gastro-enterostomy the button has been known to go the wrong way even when the small intestine was attached to the posterior wall of the stomach, but this must have been from the patient turning on the side. If the bowel were attached to the posterior part and the heaviest half placed in the bowel this ought then only to occur if the patient turned over on to the abdomen.

The condition of the diseased portions of intestine in my case is of much interest. One would certainly expect them to become contracted and atrophic as they did in Senn's experiments,§ but the diseased portion of the colon, from the anastomosis back to the caecum, was much dilated and thickened, with ulceration of the mucous membrane. Certainly the sigmoid below was contracted by new growth, but not to less than three-quarters of an inch in diameter, which would not cause obstruction to the passage of the liquid faeces discharged through it from the anastomosis opening. The equal dilatation and thickening of the portion of diseased intestine extending from the anastomosis back to the caecum might have developed before the anastomosis from the existence of the obstructing mass of growth in the caecum. There is no doubt that much of the persistent abdominal distension was due to gas in the diseased portion. The enormous dilatation of the rectum to replace the colon is interesting.

A SERIES OF CASES OF COLECTOMY.

By MAYO ROBSON, F.R.C.S.,

Senior Surgeon to the General Dispensary at Leeds; and Professor of Surgery in the Yorkshire College of the Victoria University.

In no branch of surgery has more progress been made recently than in operative interference with the intestinal canal, this being markedly shown in the operation of enterectomy.

There are practically two classes of operations performed for excision of portions of the intestines, one without any

special apparatus, as in Maunsell's invagination method or in the end-to-end suture; and the other by means of some special contrivance, such as Senn's plates, Murphy's buttons, Paul's tubes, or by the decalcified bone bobbin.

After using or seeing used all the above contrivances, I have returned in enterectomy to the use of the bobbin, which I infinitely prefer, not only on account of its simplicity and safety, but because it can be employed quickly, secures an immediately patent channel, leaves no foreign body permanently in the passage, avoids stricture by securing continuity of mucous surface, and can be adapted to any of the operations on the intestinal canal. My remarks are limited, according to the title of my paper, to colectomy, though my experience in cases of excision of parts of the small intestine, would lead me to use the same arguments, and to come to the same conclusions.

Of the five cases of colectomy I am about to relate, in four the bobbin was used and in one the button.

CASE I. Carcinoma of Descending Colon with Intussusception; Reduction of Intussusception and Removal of Tumour by Colectomy.—Mrs. B., aged 27, was sent to me by Dr. Ryan, of Sheffield, and admitted to the Leeds Infirmary, March 6th, 1894. The following history was sent with the patient: Married eighteen months; one child born August last, died five weeks after birth from tabes mesenterica.

Family History: Comes of a highly neurotic family; mother died, aged 51, from cancer of uterus.

Present Illness: June, 1893, had an attack of colic with diarrhoea, which passed off in a few days after appropriate treatment. In August, 1893, fourteen days after confinement, a similar attack occurred, and since that time the attacks have been recurring with intermission of a day or two. Some five weeks ago, on palpation of the abdomen after a seizure, a hard round mass, about the size of a small hen's egg, and situated a little above the left iliac fossa, was discovered, to remove which, thinking it might be a scybalous mass, 5-grain doses of calomel were given from time to time followed by Hunyadi water, and to relieve the intense attacks of colic, copious enemata of hot soap and water and turpentine were given. On giving the enema a difficulty was experienced in introducing beyond a pint; the patient then complained of intense pain at the seat of the obstruction, but with force the enema seemed to pass beyond it, the patient at the time exclaiming: "There, it is past now," after which quite a quart could be got in without inconvenience. It was further ascertained on admission that alime had been passed occasionally but no blood, and that constipation had prevailed for over a year; that after the first attack there had been no diarrhoea, and that the passage of flatus usually gave relief for a time. The patient was very thin, having lost a stone and a-half in weight during the six months before admission. The abdominal walls were thin and flaccid, and in the left inguinal region a hard swelling the size of a fist could be easily felt and could be moved in every direction, upwards under the ribs, down into the pelvis, and from one side of the abdomen to the other; it was not tender, and gave no pain on manipulation. During an attack the lump was forced into the pelvis, and a hard, sausage-like lump could be felt in the course of the transverse and descending colon. Rectal and vaginal examination negative.

March 15th, 1894. The skin of the abdomen having been aseptically and the patient anaesthetised by means of the C. and E. mixture, the abdomen was opened by a 3-inch incision in the left linea semilunaris, when it was found that the descending colon was intussuscepted into the sigmoid flexure, a tumour of the intestine forming the apex of the intussusception. By pressure from below reduction was easily effected as there were no adhesions. The tumour was brought to the surface, and the base of the loop of intestine containing it was encircled with an elastic tourniquet, after which the segment of colon, about 5 inches, containing the tumour was excised. The divided vessels in the cut mesocolon were ligatured, and the cut ends of the colon were united by means of a large decalcified bone bobbin. After the tourniquet had been removed, the parts which had been exposed were sponged over with a moist sponge dipped in carbolic lotion, and the abdomen was closed. The whole operation occupied thirty-five minutes. No shock followed; the bowels were moved by enema at the end of the week, and

* *Med. Record*, June, 1894, p. 609.

§ *Trans. International Medical Congress*, 1887, vol. i, p. 451.

the sutures were removed on the eighth day, when the wound was found healed, this being the only dressing required.

She was allowed to be up on April 6th, and returned home, looking and expressing herself well, on the 10th.

As is usual when the bobbin is employed, no trace of it was found in the motions. When going home she said she had not been so well for months. Some months afterwards she reported herself as quite well. The growth was a hard nodular mass, nearly completely encircling the bowel; its surface within the gut was ulcerated and grayish black in colour, and the summit was larger than the base. A finger could be passed through the lumen of the bowel at the site of the tumour. Under the microscope the growth was found to be columnar epithelioma.

CASE II. Carcinoma of Ascending Colon at Age of 14: Excision of Cæcum and Ascending Colon.—E. R., aged 14, residing at Bishopthorpe, was sent to me on September 18th, 1894, suffering from intestinal obstruction, with the history that for six months she had been losing flesh and strength, and that during this time she had suffered from constipation, with abdominal pain and occasional attacks of vomiting. Two months before admission an intensification of the symptoms had occurred, with fecal vomiting lasting three days.

On admission she was very weak, and emaciated to an extreme degree; the abdomen was greatly distended, the distension being especially marked on the right side, where a hard tumour could be felt in the course of the ascending colon. Between the time of admission and the time of operation she vomited fecal matter on two occasions.

On September 22nd, 1894, typhlotomy was performed, as the patient was too ill to bear any more serious operation, but before the distended cæcum was fixed to the surface a finger was passed into the peritoneal cavity, when it was found that the lump previously felt was a growth in the ascending colon. Intestinal drainage was effected through an india-rubber tube, giving the patient very marked relief. Her general condition improved so materially that in three weeks she was thought to be well enough to bear a radical operation.

On October 10th an incision of 4 inches was made, the typhlotomy opening being in the line of incision at its lower part. The bowel was rapidly detached from the parietes, when an elastic ligature was placed on the ileum and on the hepatic flexure of the colon, and as the tumour involved 3 to 4 inches of the colon, enterectomy was performed by dividing the ileum near its entrance to the colon and the ascending colon just below the hepatic flexure, the intermediate part, including the cæcum and ascending colon being removed.

The blood vessels in the mesocolon having been ligatured, the two ends of the bowel were united by means of a decalcified bone bobbin. The wound healed in a satisfactory manner, and the patient was discharged well on November 10th, having gained considerably in weight. The bowels were moved naturally on the fourth day after operation.

The patient was seen six months afterwards, and expressed herself as being in perfect health. A recent report of her states that she is keeping well. The tumour proved to be a columnar epithelioma, which had almost completely obliterated the lumen of the colon.

CASE III. Carcinoma of Cæcum: Colectomy.—J. S. H., aged 40, was admitted to the infirmary under the care of Dr. Barra on March 27th, suffering from loss of flesh and strength, with profound anemia. He pointed out a swelling in the right iliac region which he said he had noticed for twelve months. He had suffered from constipation, but there had been no complete obstruction. He was transferred to the surgical wards, and operation was performed on May 2nd. On opening the abdomen by an incision in the course of the right linea semilunaris widespread adhesions were found, and the omentum had to be ligatured in several places before it could be detached from the cæcum. The operation was performed exactly as in the last case, except that a Murphy's button was used instead of a bone bobbin. On the following day the patient rose from his bed during the temporary absence of the nurse, and walked across the ward to get himself some ice. This disturbed his dressings, and probably led to the suppuration which supervened. On the seventh day after the operation there was a little fecal discharge from the wound, which lasted nearly a week.

Although the wound healed by granulation, and the continuity of the intestine was manifestly established, the patient suffered from several attacks of abdominal pain and vomiting, which prevented his discharge from the hospital. These attacks were apparently dependent on the button, and it was not until the forty-fourth day that he parted with it. He was kept under observation for ten days longer, during which time he had no recurrence of the pain or sickness, and then went home on June 26th. The pathologist reported that the portion of bowel removed measured 6 inches, and that the tumour was a columnar-celled epithelioma involving the cæcum and ascending colon.

CASE IV. Fecal Fistula and Ulceration with Stricture of Ascending Colon Treated by Excision of Cæcum and Ascending Colon.—L. S., aged 12, was sent to me by Dr. Sykes, of Cleckheaton, on account of a fecal fistula in the right iliac region. The boy was extremely emaciated, and had his right thigh fixed in a fully-flexed position quite on the abdomen. There was a six months' history of purulent and three months of fecal discharge. On November 22nd, the sinus was dilated, and found to communicate with a large abscess cavity, but no distinct opening into the bowel could be felt; it was therefore purified as far as possible and packed, in the hope of securing healing by granulation. At the same time, extension of the leg by weight and pulleys was made in order to overcome the contraction of the psoas muscle. On January 24th, 1895, as the fecal discharge showed no signs of diminishing, it was decided to open out the cavity from the front, in order to try to close the communication between the intestine and the abscess cavity. This, however, it was found impracticable to effect by any simple method, and it was decided to ask the friends to grant permission for a more radical operation, which, however, was not performed until July. In the meantime, numerous plum stones and cherry stones were discharged through the fistula. On July 4th, the friends recognising that life under the conditions in which he then existed would be extremely undesirable, consented to whatever might be necessary in order to try to effect a cure, knowing that such an operation must be very hazardous. On opening the abdomen, the intestinal adhesions seemed almost insuperable, though after a time the cæcum and ascending colon were isolated from the adherent omentum and small gut. It was then found that the fistula was in the back of the ascending colon, which was strictured and ulcerated from the cæcum to the hepatic flexure. Enterectomy was performed, the open end of the ileum being fixed to the cut end of the colon by means of a bone bobbin. Unfortunately, on account of the large abscess cavity and suppurating tracks, strict asepsis was impracticable, though the parts were made as pure as possible, and free drainage of the abscess cavity through the fistula was adopted. The patient suffered severely from shock, but rallied somewhat on the second day. Although there was no distension and no increase of temperature, the pulse remained quick, and he died on July 7th, three days after operation. It was found that 7 inches of bowel had been removed, including the cæcum and ascending colon. The vermiform appendix was apparently free from disease, but the rest of the bowel was ulcerated and much thickened, and the lumen was so contracted at certain parts that it would not allow the passage of the little finger.

CASE V. Fecal Fistula Depending on Stricture of Ascending Colon Treated by Partial Colectomy and Enteroplasty.—This case has been fully reported in the *Lancet*, and need not be given in detail. The patient was a girl of 16, who had been ill for eighteen months with ulceration of the bowel, ending in abscess and fecal fistula, the latter being kept open by a stricture of the gut below the fistula. Partial enterectomy followed by enteroplasty resulted in complete recovery and perfect restoration to health.

For the notes from which the cases have been abstracted, I have to thank Dr. Oldfield and Mr. A. S. Robinson, my late and present house-surgeons. It will be noticed that out of my five cases, the histories of which are given in detail, four recovered, yielding a mortality of 20 per cent. The fourth case was of so unfavourable a character, it being next to impossible to secure asepticity, that the result was almost anticipated.

As our experience of these operations increases, and the

technique is improved on, we may reasonably hope to maintain or possibly to improve on this rate, though in so serious an operation as colectomy we cannot, I fear, hope to rival the statistics of some other abdominal operations, such as ovariectomy and cholecystotomy, the mortality of which should not exceed about 5 per cent.

The cases I have related in detail, besides their general surgical interest, present individual points worthy of remark.

In the first is the interesting fact of intussusception of the large bowel caused by the growth, relieved over and over again by injection, and finally by operation.

In the second is the fact of a malignant intestinal tumour occurring at the early age of 14.

In the third may be noted the extent of the growth with infiltration of omentum, yet compatible with a primarily successful operation.

The fourth case exemplifies the difficulty of performing successfully an extensive plastic operation in the peritoneal cavity, at the same time that a large septic abscess is associated with the part to be operated on; it also shows what extensive damage may result to the intestine by the lodgment of foreign bodies in the cecum and ascending colon.

In the fifth case we have an instance of a simple stricture of the intestine following on ulceration, completely relieved by partial colectomy and enteroplasty.

Although there may be a saving of 3 or 4 minutes in some cases by the use of Murphy's button, the contrast in the after-progress when it is employed and when the bone bobbin is used, is well exemplified by the uninterrupted recoveries in Cases I, II, and V and the retarded and anxious convalescence in Case III, where the button took 44 days to pass, and caused partial obstruction on several occasions.

Although I have usually employed two sutures—a mucous and a serous—in using the bobbin, I have not hesitated to employ only one continuous stitch to unite the whole thickness of the gut where time was an object in the case. When one stitch only is employed, the bobbin operation can be done more quickly than the button method, and at the same time I think it will give greater security against leakage, and a much firmer bond of union.

The bobbins which I first employed had the rims at the ends too prominent, and although they answered their purpose very well, the modification in shape shown in the appended diagram (1) will be found easier of application. A

Fig. 1.—Modified decalcified bone bobbin.

thin coating of shellac, if desired, around the central portion, ensures greater persistence and delayed dissolution, and with or without this modification a single continuous suture may be safely employed. This may either pass through the whole of the coats as shown in diagram (2) or may take up the

Fig. 2.

serous, muscular, and submucous coats, missing the mucous membrane, which, however, will be brought into contact with the opposite mucous coat when the buried stitch is tightened as shown in diagram (3).

Fig. 3.

Thanks to the courtesy of my colleagues, I was able to refer to all the cases, 13 in number, operated on in the Leeds Infirmary during the past two years. The record shows a mortality of 23 per cent, and as the cases are varied and the number is, for the nature of the subject, considerable, and as, moreover, the operations have been performed by five different surgeons, I think we may fairly estimate the mortality of colectomy on this basis, and not on the higher rate given in textbooks as 80 per cent.

Mr. GRIGG SMITH (Bristol) criticized Mr. Robinson's operation of typhlotomy for acute intestinal obstruction of doubtful origin. The correct procedure would have been to have brought the tumour outside the abdomen at the first operation, and not to have waited till the second. In acute cases Mr. Greig Smith brought the tumour outside, and kept it out by skewering the mesentery. He then drained the bowel till the abdomen was flat, and finally closed the artificial anus extraperitoneally. He objected to primary enterotomy in obstruction, mainly on account of the condition of the patient; his treatment was primary typhlotomy, the bowel being brought outside the abdomen, and subsequently resected calmly and deliberately without the use of an anæsthetic. Finally, a third operation might, if necessary, be performed later on for the closure of an artificial anus.

Professor KNUX (Philadelphia) related two fatal cases in which Murphy's button had been used. The first was one of gastro-enterostomy, in which the button was blocked by a plumstone which he had not succeeded in washing out of the stomach. In the second the button could not be completely closed, the two halves remaining about one-eighth of an inch apart. The patient died of perforative peritonitis, the upper end of the bowel having sloughed. It was found post-mortem that the ends of the circular suture had been left too long, and that one had caught in between the two halves of the button.

Mr. GEORGE HAMILTON (Liverpool) had performed three colectomies for carcinomatous stricture, the ages of two of the patients being 27 and 35 respectively. The first case, in which he used a bone tube, was unsuccessful. In the second he used the large—an inch and a-half—Murphy's button, this being the first time it had been employed in England. The third case was one of subacute intestinal obstruction in a woman of 70. He found a growth the size of a fist in the splenic flexure, and resected it, using the one and a quarter inch button. The operation lasted twenty-five minutes, and the patient had perfectly recovered in three and a-half weeks. Mr. Hamilton had hence great faith in the button.

Mr. H. W. ALLINGHAM had performed eight resections, of which the four done for obstruction died. He thus recommended that the operation should be done as Mr. Greig Smith had suggested. Mr. Allingham preferred decalcified bone plates to the use of the button.

Mr. HARRISON CRIPPS wished most emphatically to endorse Mr. Greig Smith's views as to the advantage of a temporary opening, as he held that a patient could but rarely stand the operation of resection when obstruction was present. Mr. Cripps considered Murphy's button the worst possible method of treating intestinal obstruction. He had recently seen four fatal cases of its use by an eminent St. Bartholomew's surgeon. Two were moribund at the operations, but the others were directly killed by the button. In one case the junction effected was perfect, but the patient died on the eighth day from perforative peritonitis caused by the button having become impacted 6 inches lower down the bowel, and having ulcerated through. The other patient died in two or three days from acute septic peritonitis due to sloughing of the intestine over the upper half of the button. Mr. Cripps held that careful and accurate suturing was better than the use of any apparatus, and that two or three minutes more or less at the operation made no difference to the patient's chance of recovery.

Professor MACLEWEN (Glasgow) stated that though usually regarded as a radical in surgery, he was in this particular conservative. Although he had always buttons ready for use, he had never yet seen a case in which there was any reason to prefer them to stitches. He was in the habit of adopting the operation in two stages for acute intestinal obstruction.

tion, but found that it was not always applicable in acute chronic cases. The best result was the union with the large intestine and some of which were still living, from eight years, and the others after two years and one year respectively.

Mr. MARY HOBBS, in his reply, agreed with the operation in two stages for acute cases, but held that it was not always possible to pull out the whole intestine with the growth at the first operation. He held that a large Murphy's button was not as good in enterostomy, as it sometimes closed the colon in its passage down. He preferred to use an incision in pylorostomy and enterostomy, but not in colostomy, where he thought the bone button better, as allowing the patient to use a continuous stitch, and protecting the line of union for several days.

COMPLICATIONS ARISING IN INGUINAL COLOSTOMY.

By HARRISON CRIPPS, F.R.C.S.,
Ret. Asst. Surgeon, St. Bartholomew's Hospital.

My experience of colostomy for malignant disease of the rectum extends to 170 cases. In far the larger number of these the operation was performed as a palliative treatment in rectal cancer, in which more or less stricture was present, though the obstruction was not complete. In the minority of cases it was performed as a means of saving life after obstruction had become absolute.

The death-rate in the two series differs widely. In the cases where the obstruction was not yet complete, the mortality was slightly less than 4 per cent. In those where the obstruction was complete it rose to nearly 30 per cent. The deduction from this comparative death-rate is that the high mortality following after colostomy for complete obstruction is not due to the operation itself, but to the condition into which the patient has drifted through relief being too long delayed. Nevertheless apart from the condition of the patient, there can be no doubt that the risk of septic peritonitis is increased when colostomy is performed on a completely blocked and distended intestine. In these circumstances the finding of the colon may be a matter of some difficulty. The small intestines, greatly distended, endeavour to crowd out of the wound and obscure the position of the sigmoid flexure, which may only be found after a good deal of manipulation. It is a very different matter handling intestine when distended than when it is flaccid and empty. The tightly stretched peritoneal investment of an inflated intestine will split and crack with a very little handling. It is like india rubber in this respect, which will split with ease when tightly stretched, but will stand a considerable amount of manipulation when relaxed. I regard these tears in the peritoneal coat of the bowel as often the starting point of fatal peritonitis. Then again the actual stitching of the distended bowel to the parietal peritoneum and skin is very difficult to accomplish without risk of the needle perforating beyond the muscular coat, and thus getting the wound contaminated before the peritoneal cavity is completely closed.

The object of this communication is not, however, to argue the advantages of an early over a late colostomy, but rather to consider what are the dangers arising when an inguinal colostomy is undertaken in good time on an undistended bowel. The complications which render the operation dangerous may be either met with at the time of operating, or may occur subsequently. I do not propose to enumerate all possible difficulties, but merely to mention those which I have actually met with in my own cases.

DIFFICULTY IN FINDING THE BOWEL.

The more experience the operator has the less likely is he to meet with trouble in this respect. If the bowel does not immediately present itself, it is best found by passing the fore-finger deeply into the abdomen, and feeling for the brim of the pelvis, and by sweeping the finger along the brim the upper part of the rectum can be felt passing over it, and by keeping the finger in contact with this it will guide the operator to the sigmoid flexure. In these cases the flexure is almost invariably nearer the middle line of the abdomen

than where your operator has been searching. In one case, notwithstanding a long search with the finger, I was unable to find the bowel. In this dilemma, which the finger was in the colon on in the neighbourhood of the rim of the incision, I ordered the nurse to give an injection of water by the rectum with a Higginson's syringe. After two or three injections of the kind I could distinctly feel a piece of intestine, which had before been overlooked, becoming distended, and was thus enabled to find the sigmoid, which was lying almost over in the right iliac region. Although I have occasionally had great difficulty in finding the bowel, I have always eventually succeeded in doing so.

ABSENCE OF MESENTERY.

This is, perhaps, the most unfortunate and dangerous complication that can be met with, and to this cause, with one exception, I owe all my fatal cases. In the great majority of cases the mesentery of the sigmoid flexure is amply sufficient to allow of the bowel being well drawn up in the wound, and safely fixed without tension; but in 3 or 4 per cent this is not so, for there is absolutely no mesentery, the bowel being bound back firmly against the posterior parietes. This is either due to the congenital deficiency, or to a malignant disease behind the colon, fixing it firmly. The question to be considered is as to what should be done after the operator has opened the abdomen and met with one of these cases. I am confident from my unfortunate experience that any endeavour to invert the skin and forcibly drag it down to the bowel by the sutures is a fatal mistake. The sutures will certainly cut through, leaving an open peritoneal cavity. The surgeon has three choices: he may either abandon the operation altogether, he may close the abdominal wound on the left side and perform a colostomy on the right side, or he may endeavour by some modification of the usual operation to fix the bowel without dangerous tension. If he abandons the operation altogether I do not consider he is to be blamed, but rather than do this most surgeons would prefer to close the wound and open the cecum or ascending colon on the right side. Although the subsequent inconvenience of a right colostomy is far greater than the left, on account of the less solid nature of the faeces in that direction, nevertheless it fulfils the chief purpose for which colostomy was undertaken, namely, the establishment of a permanent safety valve against death from obstruction. If the colon is absolutely fixed and lying at some depth from the parietal peritoneum, this is the course I would advocate. On the other hand, if the bowel is not absolutely fixed it may be possible by means of a Higginson's needle to suture the parietal peritoneum to the sides of the bowel, leaving sufficient space between the two layers for the opening. No attempt whatever must be made to draw the parietal peritoneum and the skin together, the skin, and all the structures above the peritoneum being excluded from the sutures. By merely attaching the peritoneum in this way the tension on the sutures is materially diminished. By opening the bowel opposite the mesenteric attachment, and then fixing the cut edges to the parietal peritoneum, tension on the sutures will be further diminished. The objection, however, to this is that the wound becomes at once soiled, and the chance of primary union between the bowel and parietal peritoneum diminished. In one instance I adopted the following plan so as to avoid this. Instead of making the linear incision completely through into the bowel it was made very carefully through the peritoneal and muscular layers only. These two layers were readily separated, and stripped back a little way from the mucous coat. Two sort of flaps were thus raised, the free edges of which were united to the border of the parietal peritoneum, and were fixed there with comparatively little tension except at the two angles. Two days later, when the opposed surfaces were well glued together with lymph, the opening into the bowel was completed by cutting through the mucous membrane. When this was done three strong silk sutures were passed on either side, going completely through all the coats of the bowel and the whole thickness of the abdominal wall. In any case, if the bowel has been fixed to the parietal peritoneum and skin with the least tension, the patient must be carefully watched from day to day, and on the least sign of the bowel falling back additional silk gut sutures should be at

once passed through the whole thickness of the edges of the bowel and the abdominal walls.

Apart from these instances of short mesentery, I have had but a single case in which the bowel tore away from its attachments, and fell back into the abdominal cavity. I have already published an account of this case, so it will be sufficient here to say that the accident occurred on the seventh day during a violent fit of coughing. The released bowel discharged a considerable motion into the peritoneal cavity. Fortunately I saw the case about an hour after the accident. The fecal matter was thoroughly washed out from the abdomen, and the detached bowel restitched to the wound. The patient recovered.

I have met with no instance of small intestine forcing itself out at the side of the attached bowel.

COMPLICATIONS OCCURRING SUBSEQUENT TO THE OPERATION.

Prolapse, which was such a troublesome complication in the earlier cases, is now comparatively rare, due in great measure to the fact that most surgeons at the time of operating draw out and remove the superfluous bowel, and in addition to this I find, by making the opening in the abdominal wall somewhat higher than in my earlier cases, there is much less tendency to protrusion. Indeed, I make my incision now nearly as high as the level of the umbilicus, so that the wall of the lower half of the abdomen, where the pressure is greatest, is left intact.

UNDUE CONTRACTION OF THE OPENING.

This is not an uncommon sequence, and if allowed will destroy the whole advantage of the operation. Too small an opening means a constant dribbling of fecal matter, the motions never getting freely and completely away. These contractions do not occur where the original opening has been made of proper size, and where all the wound has healed by first intention, but occur where the angles of the wound have failed primarily to unite, and where the granulations gradually become converted into firm contractile tissue. If the angles have not united properly the contraction will begin about the third week, and if at this time a little spring dilator be introduced and worn for a few hours daily for a month, the tendency to undue contraction will be obviated. If this precaution has been neglected, or be impracticable, the opening can readily be made the right size by passing the finger into the bowel, and then completely cutting through all the contractile tissue up to each angle, the depth of the cut exposing the outer wall of the bowel. The bowel is now freed a little on either side of the incision, and a curved needle and silk thread is passed through its edge, and through the tissues and skin at the apex of the reopened wound. The suture is tied, bringing the gut well up to the angle. A couple of additional sutures may be necessary at the sides. This little operation is practically painless, does not require an anæsthetic, and is generally most efficient.

Lastly, I come to a complication occurring after colotomy which I think must be rare, since I have had but a single instance. The case I will briefly narrate, for it teaches an important lesson, and had I known that such an occurrence could take place the patient's life might easily have been saved. The symptoms were so suggestive that they cannot well be misinterpreted in a future case.

I performed colotomy at St. Bartholomew's on a middle-aged man. All went well at the operation, and the artificial anus had united firmly, was of the right size, and worked well. The patient was on the eve of leaving the hospital when he was suddenly seized with sharp gripping pains referred to the region of the colotomy opening. An hour or two later he commenced to vomit. The vomiting continued for three or four hours. At this time the patient said that he felt something slip in his inside, the vomiting ceased, and the pain suddenly left him. The following day the patient felt quite well beyond a little general abdominal tenderness. A few days after he was discharged from the hospital. Ten days later he was readmitted in a dying condition. He had been vomiting for two days, and was in a state of complete collapse. He stated that thirty-six hours previously he had been seized with a similar pain to that which he had experienced prior to leaving the hospital, and had been vomiting continuously ever since. The patient died a few hours

after readmission. At the *post-mortem* examination the colotomy wound was found to have united firmly, and there was not the slightest sign of peritoneal inflammation. A loop of small intestine over a foot in length was found to have slipped down between the attached portion of the gut and the reflection of the parietal peritoneum in the neighbourhood of the anterior superior spine. The canal thus formed was nearly an inch in length, and was bounded on the inner side by the bowel forming the colotomy opening, and in front and behind by the parietal peritoneum, and on the outer side by the reflection of the parietal peritoneum. This canal would about admit one finger through it, and was the seat of the strangulation. At the *post-mortem* examination the bowel could be easily withdrawn through the canal. There can be no doubt that the first attack was due to the slipping of gut through this channel from which it spontaneously released itself. Prompt abdominal section would have saved this patient.

I have merely related, Mr. President, the few complications I have myself met with in colotomy. Doubtless there are other surgeons present who could inform us of complications not mentioned in this paper. The mortality from inguinal colotomy is very small, and I trust may be yet further reduced by considering the nature of the complications which form the chief cause of death. The operation in properly selected cases is of great value, and at present is the only known means of prolonging life and relieving suffering in cases of cancerous stricture of the rectum for which excision is impossible.

THREE CASES OF SACLESS HERNIA OF THE SIGMOID FLEXURE THROUGH THE LEFT INGUINAL CANAL.

By WILLIAM ANDERSON, F.R.C.S.,
Surgeon to St. Thomas's Hospital.

SACLESS hernia of the sigmoid flexure through the left inguinal canal has not hitherto been recorded, so far as I am able to trace, although both vesical and cæcal hernie have been seen in the same situation. I propose to read a summary of the main features of three examples.

The cases all came under notice in the wards of St. Thomas's Hospital between the months of May and November (inclusive) of last year. The patients were strong, healthy, working men, one aged 41, the other two 44; and the duration of the hernial protrusion before coming under surgical treatment had been a few months only in two instances and twelve years in the third. In two cases the hernia was oblique, and entered the scrotum; in the other—a bubonocoele—it appeared to be direct, and was associated with an undilated processus vaginalis in the course of the canal. In two cases an inguinal hernia on the right side was also present. In one case the left hernia was incarcerated at the time of admission; in the others it was readily reducible, but it was observed that it returned into the abdomen without the sudden slip commonly noticed in replacing an ordinary enterocoele.

On cutting down upon the tumour it was found in each instance that the dissection exposed the muscular wall on the convex side of a short coil of bowel, while on the concave side the tube was covered for about half its circumference by peritoneum, which extended upwards into the abdomen. On opening the peritoneal infundibulum distinct plicæ adiposæ were seen on the serous segment of the gut in two of the cases; in the other (the first of the series) these were not visible, probably because the bowel was not drawn down sufficiently into the wound. In all, however, the intestine was traced upwards by the finger into the iliac fossa towards the hinder part of the iliac crest, and was bound down to the fascia iliaca by a layer of peritoneum which ran over the front of the gut without forming a mesentery.

The treatment adopted was to sew up the exploratory opening in the peritoneum, to reduce the gut, and finally, in the second and third cases, to close the inguinal canal with sutures, with a view to retain the intestine in the iliac fossa as long as possible, in the hope that the tendency to descend might be lessened. The result has so far been fairly good. In the second case the cure has held good during a period of

nine months with the aid of a truss; in the other two the protrusion recurred soon after work was resumed, but in a less troublesome form than before.

The anatomical conditions essential to the occurrence of this form of hernia have, I think, never been described in our textbooks, although they were alluded to as a possibility by Joseph Moleshe in his *Atlas of Surgical Anatomy*. By a curious coincidence, not only did three examples of the pathological result of the variation present themselves in the hospital practice of one surgeon, but two instances of the variation itself appeared in the dissecting room of the same hospital within the same year. One of these is now brought forward. The sigmoid or ilio-pelvic coil, which includes the so-called "first portion of the rectum," is usually fixed to the posterior pelvic wall by a well-marked mesentery. This peritoneal duplication, as our experience in the operation of inguinal colotomy shows, is of a very variable length, sometimes sufficient to allow an embarrassing degree of extrusion of the gut through the parietal wound, at others scarcely permitting it to reach the incision at all; occasionally, as we now see, it is absent altogether, the intestine running along the iliac fossa, as the descending colon runs down the loin, behind the peritoneum, and invested by it only over half or two-thirds of its circumference. In such a condition, if the subperitoneal tissue which unites the gut to the iliac fossa be lax, the intestine may wander, and may find its way through the inguinal canal into the groin or scrotum; and it is possible that in the female subject it would in like manner enter the crural canal, in either case drawing after it a pouch of peritoneum adherent to the concave side of the coil.

In the radical cure of the ordinary form of inguinal hernia the most essential point is the obliteration of the sac; but in cases like those now described there is no sac to close, and no treatment of the inguinal canal can offer more than a moderate probability of a permanent cure. It is desirable, however, to make the attempt.

Mr. BIDWELL described a similar case, which had, however, become strangulated, and which, after operation, broke down, leaving a fecal fistula.

A SIMPLE FORM OF EXHAUSTION PUMP FOR USE AFTER SUPRAPUBIC CYSTOTOMY.

By CHARLES W. CATHEART, F.R.C.S.,

Assistant Surgeon, Royal Infirmary, Edinburgh.

The following apparatus will be found to be of service in withdrawing the urine after suprapubic cystotomy by way of the wound for by the urethra if desired, as soon as it reaches the bladder, with considerable advantage to the patient and nursing staff. Besides a douche can, some india-rubber tubing, and a pail, we require a screw clamp, a small glass Y or T tube, a second piece of glass tubing bent like a capital letter S, and a third piece bent at a right angle to go into the bladder. These are joined together as illustrated in the diagram and the apparatus works as follows:

The douche can filled with water is fixed above the head of the patient's bed, the Y tube is fastened with a large safety pin to the edge of the mattress opposite the patient's pelvis or loins, and the part below the Y is made to hang over a pail on the floor. The screw clamp which controls the rubber tubing between the douche and one arm of the Y tube is then relaxed, so as to allow the water to flow very slowly, in fact only by drops. It accumulates in the S tube, and as it tends to run out produces a negative pressure in the other arm of the Y tube, that is, the one which is connected with the tube in the bladder. It thus withdraws urine from the bladder, and this in turn as it runs down the S tube into the pail increases the negative pressure in the bladder arm of the Y, and so on.

The amount of negative pressure obtainable depends on the distance between the branching point of the Y tube and end of the india-rubber tube above the pail; about a foot will generally be found sufficient. A very small outlet at the clamp is all that is required, and at the fastest the flow into the clamp arm of the Y must be less than the possible outflow through the stem below, otherwise there could be no

negative pressure in the bladder arm of the Y tube. This will be better understood by considering what would happen if the conditions were reversed. If we were to diminish the outlet below the Y tube and increase the inlet on the douche arm, the water would flow up the bladder arm of the Y into

the bladder. Thus nothing is gained by increasing the rapidity of the flow beyond a steady dropping from the clamp. The accumulation in the S tube will transform this into a rapidly intermitting flow with which the urine from the bladder is mingled.

The apparatus has worked very satisfactorily after operations for extroversion of the bladder, as well as after suprapubic cystotomy, and may, I hope, be found useful after other operations on the genito-urinary tract, and possibly as a means of draining the pelvis in septic conditions.

A SUCCESSFUL CASE OF LAPAROTOMY FOR INTUSSUSCEPTION IN AN INFANT, WITH REMARKS ON TWO OTHER CASES SIMILARLY TREATED.

By FREDERIC EVE, F.R.C.S.,

Surgeon to the London Hospital and to the Evelina Hospital for Sick Children.

CASE I.—A female child, aged 11 months, was admitted to the London Hospital on May 29th, 1895, at 4 p.m. The mother stated that the child was well until one hour before, when she was sick, and blood came from the back passage. She was at once taken to the theatre, placed under chloroform, and an injection of warm water, $1\frac{1}{2}$ to 2 pints, was given with a siphon and funnel. The pressure used was very considerable, the funnel being raised above the couch at least 12 inches; and the injection was continued for a considerable time, about 20 minutes to half an hour. It was combined with manipulation of the abdomen, the intussusception being grasped in the hand and squeezed, so that pressure was exercised downwards towards the right iliac fossa.

Under this treatment the intussusception gradually disappeared, and from occupying the epigastric region the swelling gradually passed down to the right iliac region. But notwithstanding the exercise of very considerable force with the fingers, grasping the bowel above the swelling, a small ill-defined lump still remained which could not be reduced. The abdomen was therefore opened in the middle line, and it was found that a slight protrusion of the ileo-caecal orifice, to

the extent of about $\frac{1}{2}$ to $\frac{3}{4}$ inch, into the cecum persisted. This was readily drawn out and the abdomen closed, the operation only lasting a few minutes. Immediately after the operation the temperature was 98.5° ; it rose steadily, reaching 104° on the evening of the next day. From that time it declined, gradually reaching the normal on the evening of the second day, and did not again ascend. Convalescence was uninterrupted, and she left the hospital on June 16th.

CASE II.—A male, aged 2 years, was admitted to the London Hospital, February 26th, 1893, with symptoms of intussusception, which had existed six days. A cylindrical tumour occupied the right hypochondrium. A copious rectal injection of warm water was given under chloroform in the inverted position. During the injection the tumour gradually disappeared, and finally only a slight indistinct fulness in the cecal region could be made out. This it was thought might be due to swelling of the intestine which had been invaginated. Subsequently two motions containing fecal matter were passed. Next day the symptoms with the tumour returned; the abdomen was opened in the middle line, and the intussusception readily reduced. The child continued well until the second day when the temperature rose, and he was found to be suffering from broncho-pneumonia. Death took place on the third day with a temperature of 104.8° . At the post-mortem examination there was no evidence of peritonitis, but the lower lobes of both lungs were deeply congested and consolidated; to this the fatal result was probably due.

CASE III.—A female child, aged 11 months, was admitted to the Evelina Hospital on July 31st, 1893. The symptoms, which were acute, had existed for twenty-four hours. A sausage-shaped tumour passed upwards from the pelvis and the left iliac region, and extended in a curved manner across the abdomen below the umbilicus. The apex of the intussusception could just be felt in the rectum. The child was somewhat cold. Influenced by the disappointing result of rectal injection in the case above related (Case II), I at once proceeded to perform laparotomy. Some little difficulty was experienced in exposing the intussusception, as the cecum had become twisted over on itself, and occupied the left side of the abdomen. Moderate traction upon the entering intestine had no effect, but reduction was readily effected by grasping the upper part of the rectum where the intussusception terminated, and gradually kneading it upwards by pressure. The invagination took place at the ileo-caecal valve. The child was placed on a hot water bed during the operation. She bore it well, and continued in fair condition until 11.45 P.M., when a large quantity of blood was passed per rectum, and she became collapsed. Soon after vomiting of blood commenced, and continued incessantly until death took place at 12.45 midnight, the temperature having in the meantime risen to 104.2° .

Remarks.—Cases I and II bring out prominently the fact—which is still further emphasised on referring to the histories of previously recorded cases—that recurrence is extremely liable to take place after apparent reduction of an intussusception by injection of water or of air. This recurrence is evidently due, in the large class of ileo-caecal intussusceptions, to the ileo-caecal orifice still remaining slightly invaginated into the cecum. In Case I this could be felt as a distinct nodule, and its presence determined me to operate at once, fortified by my experience in Case II, in which the swelling was vague and indistinct, and could only be felt occasionally by palpation. Yet in both these cases I am of opinion that the injection served a useful purpose by reducing the bulk of the intussusception, for in both instances the operation lasted only a few minutes, and therefore involved very little disturbance of the intestine. Consequently there was slight shock, and replacement could be effected through a small wound; whereas in Case II, where no injection was used, the operation was somewhat prolonged, and reduction only effected after considerable manipulation of the intestine and through a larger wound. I would therefore insist that where an intussusception has apparently been reduced by injection the greatest pains should be taken to ascertain that the reduction has been complete, and that if any uncertainty exists on this point the abdomen should be opened at once. Another point to which I wish to draw attention in reference to these cases is the mode of death in those which terminate

fatally after laparotomy. In Case III it will be observed that the temperature on the evening of the day of the operation rose to 104° . In another case under the care of one of my colleagues the temperature on the evening of the operation rose to 105° , and the child died.

In a successful case recorded by Mr. Barker¹ in a child aged 4 years, the temperature also on the evening of the day of operation rose to 104.4° , while in another fatal case in a child aged 5 it reached 107.8° . In my own successful case (I) the temperature gradually rose, reaching 104° on the evening of the day after the operation. I might also quote other cases in which the same fact was observed. It may be inferred that the pyrexia in some instances is largely concerned in bringing about the fatal result. A rise of temperature after laparotomy should therefore be anticipated, and directions given to reduce it by cold sponging and the application of ice to the head. Its cause appears uncertain. Sepsis may be excluded since the pyrexia usually occurs within a few hours of the operation, and when recovery takes place, rapidly subsides. Further, in fatal cases, no evidence of peritonitis may be found. It may probably be referred partly to reaction from shock, and partly to absorption of blood and serum poured out into the coats of the congested and swollen intestine involved in the intussusception; or, again, in some cases of longer duration to enteritis. A third cause of death to be guarded against is broncho-pneumonia. This was the cause of death in Case II, also in a case published by Mr. Barker,² which otherwise would have recovered.

A SUCCESSFUL CASE OF REMOVAL OF THE ENTIRE UPPER EXTREMITY FOR INJURY BY BERGER'S METHOD.

By THOMAS F. CHAVASSE, F.R.C.S.,

Senior Surgeon to the Birmingham General Hospital.

THE patient was a man, aged 32, whose left forearm was completely severed immediately below the elbow-joint, the skin and soft parts of the arm being also injured as high as the shoulder-joint, the result of entanglement in machinery. The limb, together with two-thirds of the clavicle and the scapula were removed within an hour of the accident. The patient made a rapid recovery. Attention was directed to the advantages of Berger's method of amputation in such instances, and the statistics of previously reported traumatic cases, in which the entire upper limb had been surgically removed were commented upon.

ON THE TREATMENT OF RESISTANT TALIPES EQUINUS IN ADULTS AND ADOLESCENTS.

By E. MUTHREAD LITTLE, F.R.C.S. Eng.,

Surgeon to the National Orthopaedic Hospital, London.

THERE are certain cases of talipes in adults or adolescents usually congenital in origin, in which, as the result of treatment, *varus* is not a strongly marked characteristic, but in which *equinus* persists. In such the adduction and outward rotation of the fore part of the foot may generally be overcome by subcutaneous operation combined with forcible stretching with the wrench and gradual correction by means of Senap's shoe, or other appliances.

Some progress may also be made towards flexion of the foot upon the leg, but after a time it will become obvious that the resistance encountered is due to the shape of the bones entering into the ankle-joint, and that all that can be done by dividing and stretching the soft parts fails to bring the sole of the foot up to a right angle with the leg. Some operation on the bones then becomes necessary if the patient is to be enabled to walk with comfort and without pain.

Excision of the astragalus appears to be the operation most in favour with surgeons, if we may judge from the statistics of 436 operations on the bones in club-foot, collected by Dr. Augustus Wilson, of Philadelphia.¹ I would venture to suggest,

¹ BRITISH MEDICAL JOURNAL, vol. II, 1894.

² Trans. American Orthopaedic Association, vol. VI, Philadelphia, 1894.

however, that this is a rough-and-ready procedure, the effects of which cannot be accurately foretold, that it shortens the limb, and needlessly mutilates the foot, and that its results are often unsatisfactory, so much so that further operations often have to be undertaken.

Even in the worst of these cases the bony "block" is not encountered until flexion reaches within about 15 degrees of the right angle. If the range of movement already existing can be preserved, but 90 degrees be substituted for 105 degrees as the flexion limit, the result must, I think, be considered satisfactory. This end can, I submit, be attained by removing a wedge from the neck of the astragalus and anterior portion of the os calcis, leaving the body of the astragalus *in statu quo* between the malleoli. If the base of this wedge be directed outwards as well as upwards, any varus tendency can be corrected at the same time as the equinus.

The annexed sketch of the skeleton of a normal foot shows the wedge to be removed:

Fig. 1.—Diagram of skeleton of left foot seen from outer side.

In any average-sized adult foot, such as that of the patient whose case is described, the removal of a wedge having a base half an inch thick means the gain of 8 or 9 degrees of flexion. A wedge of this size is easily removed without going beyond the neck of the astragalus; by including the head also in the wedge, the gain may be nearly doubled, but this can seldom be necessary.

The following case illustrates the method:

J. T., aged 19 years, is the eighth of ten children, of

Fig. 2.

whom five are the subjects of congenital talipes equino-varus. He has been treated in various ways since birth, and now presents the following condition:

Both feet are considerably adducted and rotated outwards. The soles can only be placed on the ground by rotating the limbs inwards. There are bad corns on the outer edges of the feet on which he habitually walks. The head of the astragalus is prominent, and easily to be felt beneath the skin on the outer side of the dorsum of the foot. Movement at the ankle-joint is limited, and the feet cannot be brought to nearly a right angle with the leg, a firm unyielding resistance seeming to oppose further flexion. The legs are thin, all the muscles being very poorly developed owing to want of use. The two sides are almost alike, except that perhaps the right foot is the more deformed. Fig. 2 shows ink prints of the feet before and after operation.

It was determined to give a thorough trial to subcutaneous section and stretching, but without much hope of overcoming the resistance to flexion. The plantar fascia were therefore divided together with some of the subjacent muscles, and the feet were, with the aid of the wrench and Scarpa's shoes, abducted and put into fair position; but as despite section of the tendines Achillis, flexion beyond about 100° was impossible, the following operation was undertaken on the left foot. An incision was made from above downwards over the neck of the astragalus, and exposing the ankle-joint. An examination of this joint showed that the front part of the trochlea of the astragalus locked firmly against the tibia on flexion, and that only a very wholesale removal of bone in this situation would be of any use. The neck of the astragalus was then removed with the chisel, and the incision through the skin having been prolonged from its lower end downwards and backwards on the outer surface of the foot, the calcaneum was also divided, the portion removed from the two bones occupying a wedge with its base directed upwards and outwards. A carpenter's chisel was used. The bones were soft and fatty, and easily cut, and bled very little. Hemorrhage was slight. The skin wound was closed by suture, and a drainage tube passed through a puncture in the sole. Cyanide gauze and wool dressings were applied, and the foot and leg secured in the best position attainable on a wooden back splint. There was a good deal of oozing of blood during the first few days, controlled by pressure. The temperature never rose above 100° F., but healing went on very slowly, and was not complete till three months had elapsed, when a small remaining sinus finally closed.

Fig. 3.

This delay was attributed to the condition of nutrition of the bones, no doubt largely due to want of use and the pressure of the straps of the apparatus worn. The patient was

therefore sent away into the country, and directed to wear no apparatus on the right foot, and to use it as much as possible. A boot with a single steel support to the calf was fitted on the left foot.

Six months after the last operation on the left foot the patient returned to London, when the right foot presented the appearances shown in Figs. 3 and 4.

Fig. 4.

The same operation was then performed on the left foot as on the right, except that the ankle joint was not exposed and examined. The bones were more vascular and less fatty

Fig. 5.

than in the right foot. No drain was used. The dressings had to be changed twice in the first fortnight, owing to serous oozing, but the wound was quite healed on the forty-fourth day. The temperature remained normal throughout. At the present time (July 3rd, 1895), fifteen months after the first, and nine after the second operation the feet are in good position. There is no tendency to varus, and they can both be flexed to a right angle. The patient is wearing ordinary boots, and says that he can walk four or five miles.

Figs. 5 and 6 show the present condition.

Fig. 6.

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

CHLORIDE OF AMMONIUM VAPOUR IN MIDDLE EAR DISEASE.

WHOEVER attaches a Richardson's—continuous—spray apparatus by the proximal end of the elastic ball compressed by the hand, to the distributing tube of a Vereker's chloride of ammonium inhaler, and lastly a Eustachian catheter to the distributing end of the spray apparatus, will have a most efficient means of applying this gas to the middle ear. A few squeezes must first be given to the ball so as to fill the apparatus with gas before introducing the catheter. Again, if such a catheter or even a glass tube drawn to a point be affixed to a Higginson's syringe, the best and handiest means of syringing the ear that I know of will be afforded. The small and practically continuous jet applied with any force desirable almost immediately tunnels a hole in the hardest cerumen, and quickly allows of that reflex current necessary for its removal, doing away with the need for clumsy ear syringes. These means I have used for years. I have also conceived the idea of applying chloride of ammonium or carbonic acid gas to the bladder in certain catarrhal states by a modification of the first idea, and through a double channel catheter, but I cannot yet speak of the utility of this.

Finsbury Pavement, E.C.

JAMES MACMUNN.

CÆCAL ABSCESS FOLLOWED BY PORTAL PYÆMIA AND SECONDARY ABSCESSSES OF THE LIVER.

G. C., aged 26, complained of illness on June 28th, 1895, and was seen by me on July 2nd. He then complained of nausea and dull aching pains about the umbilicus, and of feeling "shivery" at times. Two days later he became jaundiced, the urine contained a large quantity of bile, and the stools were grey: the pulse was 100, and the temperature 101° F. On July 5th he complained of pain in the right shoulder, great thirst, and flatulence. The liver dulness was not increased, but there was marked tenderness over the whole organ. During the previous night he had had several severe rigors, which recurred at intervals throughout the day. On July 6th, 7th, 8th, and 9th his pulse and mid-day temper-

ture varied a little, but the rigors continued at intervals of six or seven hours with increasing severity, and lasted as long as half an hour. The sweating after them was most profuse.

On July 10th there was no amelioration in his symptoms, and, after a consultation with Mr. R. C. Lyle, it was decided to explore the liver by means of the aspirating needle, as the symptoms pointed to hepatic abscess, though we were without guidance as to its situation. I introduced the needle in five places over the right lobe with negative results, except that from one of the punctures I drew off $\frac{3}{4}$ ij of blood. This seemed to give slight but only temporary relief, and his condition daily became worse. The rigors continued, the abdomen became tympanitic, and the fauces and inside of mouth were covered with aphthous patches. The mid-day temperature was usually about 100° F. The liver dulness in the mammillary line increased to 5 inches. On July 16th bile reappeared in the motions, but this was followed by no improvement in his general condition. On July 18th his pulse was 100 and temperature 100° F. On July 20th he became collapsed. He revived somewhat later in the day, but died the next day.

Post-mortem Examination.—The lungs were healthy and crepitant throughout. The pericardium contained $\frac{3}{4}$ v or $\frac{5}{8}$ v of bile-stained serum, and the left ventricle a large ante-mortem clot. The liver weighed 5 lbs. 6 ozs., was soft, dark in colour, and mottled with purplish patches. The right lobe was adherent to the diaphragm. On cutting sections, throughout the whole liver numerous small abscesses were seen and one larger one near the fissure. The hepatic veins were completely filled with pus. The spleen weighed 1 lb. 6 ozs., and was dark and pulpy. The kidneys were both congested. When the vena porta was cut through pus welled out in large quantity. The intestines were much congested, and the peritoneum showed signs of general inflammation. The caecum was intensely red and adherent. On examining it more closely a small abscess cavity was found upon its outer and posterior part. It had been cut through in taking out the caecum, and would probably have held a small hazel nut. The coats of the gut were much thickened and covered with lymph. The branches of the portal vein proceeding from this region all contained pus. The appendix vermiformis was healthy.

Remarks.—It is somewhat curious that the patient should not have complained at an earlier date than he did, for it is quite evident, from the short space of time which elapsed between his first complaints and the appearance of jaundice, that he must have passed through the earlier stages of his illness before he desisted from his work. It is also curious that the usual signs of typhilitis, such as pain, tenderness, dulness, etc., were entirely absent when his abdomen was first examined.

Great Bardfield.

RICHARD RICHMOND, M.D. Edin.

HEREDITY OF APPENDICITIS.

THE question of heredity as a cause of appendicitis, raised by Dr. Armstrong Atkinson, receives further illustration from the following cases which came under my notice many years ago:

Out of a family of four sons and one daughter, the second son died of acute general peritonitis, which was shown by examination after death to have resulted from a perforating ulcer of the vermiform appendage. He had had several previous attacks of what I supposed was typhilitis due to his chewing wheat in the exercise of his calling as a miller. The youngest son, also a miller, had a severe attack of appendicitis, followed by iliac abscess, which relieved itself by bursting into the rectum. The daughter, a single woman, has had two well-marked attacks of either typhilitis or appendicitis, from which she made good recoveries. Lastly, an elderly woman, a cousin of the above, died of acute peritonitis originating in inflammation and probable perforation of the appendix.

Although I have met with many cases of appendicitis, both with and without perforation, the cases now related are the only instances I have known of the disease affecting more than one member of a family.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

HENRY TRENTHAM BUTLIN, F.R.C.S., D.C.L., President, in the Chair.

Tuesday, October 15th, 1895.

THE SPONTANEOUS FRACTURE OF URIC ACID CALCULI.

DR. PLOWRIGHT read a communication on this subject. The patient was a man aged 72, from whose bladder were removed 236 fragments and 6 entire calculi in the process of spontaneous fracture. The base of the bladder was occupied by several sacculi or pockets about half an inch across, which contained the calculi, the fragments, and pus laden urine. The sacculi were formed by hernia-like protrusions of the mucous membrane between the reticulating muscular fibres of the bladder, and were so placed as never to be emptied during life. The entire calculi were mapped out into segments by elevated ridges and upon section each segment was seen to be lifted up, being separated from the nucleus below, and from the other segments by cracks or fissures sufficiently wide to admit the point of a penknife. They were held together only by the ridges on the exterior of the calculus. These ridges consist of uric acid with a trace of ammonia, as pointed out to the author by Dr. Ord. The same substance in the form of a greyish white deposit covers not only the exterior of all the calculi and fragments, but extends into the interior of the fissures, covering their sides with a granular or nodular layer. (Fig. 1.)

FIG. 1.

Towards the outer extremities of the fissures, opposite the one or two outer concentric laminae of the calculus, it is deposited much more abundantly, so as to constitute an obtuse wedge when seen in section (Fig. 2), by the increase of which

FIG. 2.

the fissure is opened. The fragments are, as a rule, more or less wedge-shaped, but convex externally where they correspond to the exterior of the calculus, and concave internally when they have been lifted away from the nucleus. In some cases only one or two segments have been lifted out from a calculus (Fig. 3). On the surface of the calculi the deposit often forms blister-like elevations, which may be perforated in the centre, and resemble volcanic craters. On section the upper wall of these blisters is seen to consist not only of the whitish-grey deposit, but fragments of the outer concentric laminae of the calculus have been upheaved by and remain embedded in it

(Fig. 2), and are easily recognisable by their yellow colour and striation. When pressure is applied to a calculus with sufficient

Fig. 2.

force to crush it, fracture takes place not only by a separation between the concentric laminae, but also at right angles to them along what may be called the planes of radial cleavage. The tendency to radial fracture can often be observed in the sections of calculi in museums; but it is best shown in the structure of artificial calculi as pointed out by Rainey in his book on *Molecular Coalescence*. We may, therefore, regard a calculus as an assemblage of pyramids arranged with their bases externally. In the case under consideration the new deposit of uric acid on the exterior has taken place in such a manner as sometimes to lift up the outer laminae, sometimes to open the interpyramidal sutures. When once an opening has been made between two pyramids, the fissure spreads inwards, the deposit acting as a wedge, so that the calculus becomes split in exactly the same way as a log of wood may be. The transverse section of an exogenous trunk presents many similarities to the section of a calculus. The pith answers to the nucleus, the annular rings to the concentric laminae and the medullary rays to planes of radial cleavage. If a wedge be driven a short distance into such a log of wood parallel to its length and pressed forcibly sideways, it would lift a segment out of the trunk. The fissure between the wood fibres passes first inwards towards the pith, but when the wedge is pressed sideways the fissure turns off at right angles, taking the direction of the annular rings for a certain distance, but if the sideways pressure of the wedge be continued the fissure will turn upwards in the direction of the medullary rays, and a piece of wood will be prised out. The process is identical with these calculi, the lateral pressure being caused by the wedge-like deposit shown at Fig. 2. Rainey showed in the work above mentioned that when the artificial calculi formed by the action of potassium carbonate or solutions of gum arabic were placed in denser solutions of the colloid than that in which they were originally formed they tended to disintegrate. This is just what has happened in the present case. The lower parts of the calculi were continually immersed in the pus-laden urine of the pocket, while their upper portions were bathed in comparatively pure urine.

Dr. W. M. ORD had exhibited specimens of spontaneous fracture at different times, though they did not all agree with that shown by Dr. Flowright. That the fractures were spontaneous or had occurred during life was evident in the presence of unconformable additions to the older strata of the fragments. Usually the disrupting force arose from within, and was due to expansion of the deeper parts or nucleus of the calculus. There was a more subtle disintegration which proceeded from without inwards, and arose from changes in the circumambient colloid; but he did not follow the author in thinking that the deposition of urate of ammonium was the cause in the present instance.

Mr. REGINALD HARRISON observed that Bigelow used to believe that the contraction of the bladder was the cause of the spontaneous fracture; this could not apply in the present instance, as the calculi lay in relatively capacious saeculi, as in test tubes exposed to experiment. He imagined that at

some future period the facts of spontaneous fracture might serve as a basis for a scientific method of treatment.

Mr. W. G. SPENCER could not understand where the disrupting force came from on the author's supposition; for the fissures must have been present before the urate, otherwise the latter could not have penetrated the substance of the calculus. He thought, as Dr. ORD had stated, that the disrupting force arose from within. The "blistering" of the calculi possibly resulted from the evolution of carbonic acid from decomposition occurring in the uric acid or urate.

Mr. BUCKSTON BROWN had described two or three cases of this kind of fracture occurring in cases of sacculation or of post-prostatic pouch. In the latter condition there was not infrequently met with a semilunar form of calculus, which he attributed to the spontaneous fracture of calculi in such a pouch having been followed by their reunion from fresh deposit; the final concretion in this manner came to be moulded to the space in which it was found. He adopted the author's view that in cases of spontaneous fracture lithotomy was to be thought of as against lithidity.

Dr. FLOWRIGHT, in reply, admitted the difficulty offered by his explanation, but he thought there was evidence to show that the process of crystallisation might exercise a disruptive force, and that the crystallisation of the intruding urate would occasion fracture of the calculi.

PRIMARY SARCOMA OF VAGINA IN A CHILD.

Mr. D'ARCY POWER exhibited the pelvic organs of a child 2 years and 4 months old, who died with symptoms of uremia, there being acute retention of urine. The illness dated about 14 months back, and was shown in purulent discharge from the vagina, and the protrusion of polypi, many of which were scraped away by the general practitioner. After death no growths were discovered elsewhere. The vagina was much dilated, and from its right wall there projected a mass of new growth which partially subdivided the canal. The whole of the vaginal mucosa was beset with polypi, some of which were pedunculated and myxomatous, others of the round-celled sarcomatous structure like the main growth.

The PRESIDENT had recorded a somewhat similar case, in which the tumour, however, involved the bladder and urethra as well as the vagina.

MULTIPLE POLYPI OF STOMACH AND INTESTINE.

Mr. WILLIAM COLLIER recounted the case of a man, aged 21, who a year before admission began to suffer from abdominal pain and intermittent sickness, with constipation. When admitted no diagnosis was at first possible, but with exacerbation of pain and sickness a tumour was felt about the pyloric region and thence extending downwards. Intussusception was now diagnosed, and after laparotomy this was reduced. Death, nevertheless, took place with little change in the symptoms. After death polypi were found projecting from the stomach and large intestine, but in greatest numbers into the upper part of the small. They were innocent in nature, and many were furnished with long pedicles.

TERTIARY SYPHILITIC LESIONS OF LYMPHATIC GLANDS.

Mr. JACKSON CLARKE thought that tertiary syphilitic lesions were somewhat more common than was generally believed. He had recently observed an instance in an out-patient at the North-West London Hospital. A woman, aged 42, who came for treatment from time to time for tertiary lesions of the skin, nasal fossae, etc., reappeared after an unauthorised interval of non-attendance in a condition of marked anemia and complaining of lumps on the left side of the neck. These proved to be the deep cervical and axillary glands, which were as large as filberts and hard. At the time there were no active lesions elsewhere. The swellings rapidly subsided under iodide of potassium. He had only once observed gumata in lymphatic glands in the course of about 1,000 necropsies. This was in the case of a man, aged 25, who was admitted into St. Mary's Hospital under Sir William Broadbent complaining of pain in the right side of the chest and in the right lumbar region. There was hæmaturia and slight fever. He had several attacks of pain (accompanied by dyspnea and collapse) in the right side of the chest. He died in one of these attacks some days after admission. After death the

right renal vein was found to be occluded by clot, the right kidney was slightly enlarged, pale, and fibrosed, and there was a circumscribed ulcer in the pelvis of the kidney. The right lung contained several recent infarcts. In the liver were numerous gummata. The cervical glands, which had been noticed to be enlarged during life, were found to contain gummata. In some cases there was a difficulty of distinguishing between syphilitic and tuberculous glands. As an instance Mr. Clarke mentioned the case of a child, aged 2 years. When the patient first came under notice there was around the base of the glans penis a raised indurated sore. The history was that the child had been circumcised. All went well for four weeks, when the sore began to form. The lesion had been present for three weeks when the child was brought to hospital, at which time there were, besides the sore, marked swelling of the inguinal glands, and a general eruption of macules, papules, pustules, and some tense bullae. There was also a slight snuffling. The child was treated with mercury for three weeks, and the rash disappeared, but the inguinal glands continued to enlarge and began to soften. The glands were removed, and sections showed typical tuberculosis with characteristic bacilli. In this case there might have been a mixed infection, but no exposure to syphilis could be traced.

The President observed that tertiary disease of the lymphatic glands was not sufficiently recognised; he had seen cases himself which were rapidly benefited by iodide of potassium. As a rule such glands were more indolent than those infected with tubercle, and were more angular in figure. Such tertiary lesions did not follow tertiary lesions of parts in anatomical relationship.

CARD SPECIMENS.

Dr. A. A. KANTHACK: (1) Dissecting Aneurysm; (2) Cylindroma of Large Intestine; (3) Diffuse Primary Sarcoma of the Liver.—Mr. TARGETT: Old Injury of the Humerus from an Egyptian Mummy.

CLINICAL SOCIETY OF LONDON.

RICHMAN J. GODLEE, M.S., F.R.C.S., Vice-President, in the Chair.

Friday, October 11th, 1895.

POSTPONEMENT OF PRESIDENT'S ADDRESS.

In the unavoidable absence of the President (Dr. Buzzard), the delivery of his introductory address was postponed.

BONY ANKYLOSIS OF THE TEMPORO-MAXILLARY ARTICULATION.

Mr. ARDUBENOT LANE read notes of four cases treated by excision. The first was a boy, aged 9, the duration of the ankylosis being less than three years; the second, a girl, aged 12, and the duration less than two years and a-half; the third, a boy, aged 4, and the duration less than three years; the fourth, a girl, aged 10, and the duration less than three years. All these were cases of complete bony ankylosis, and the results obtained were most satisfactory, the wounds healing immediately, and a perfectly new joint developing very rapidly. Mr. Lane considered that the occasional failure of this operation resulted from an insufficiently free removal of bone.

Mr. HOWARD MARSH thought the interest of the paper would be much enhanced if the cases could be seen. The operation was a rare one; he had never had occasion to perform it. He asked if there was resultant deformity; or if the jaw was rotated to either side?

Mr. WALLIS had found the recorded results of such cases very unsatisfactory. He had seen a case of double ankylosis in a woman, aged 30, treated by his colleague, Mr. Bloxam, who, after experiencing difficulty in finding the articulations, removed both heads of the lower jaw. After the operation the lower teeth were removed, and replaced by others; and six months ago, when last seen, she had very good movement of the jaw.

Mr. TARGETT had also found difficulty in arriving at the articulation in the case of a boy, aged 7, who had suffered from scarlet fever. The lower jaw was completely fixed, but being behind the upper the boy could take liquids. As section of the neck of the bone scarcely effected any improvement, he chiselled away the ankylosed head of the jaw.

The patient had since regained every form of movement, and could just put the lower jaw in front of the upper.

Mr. A. E. BANKS had operated upon two cases. One was that of a young lady, aged 15, with ankylosis after injury produced ten years before by a fall. She could only with effort separate the lower about an eighth of an inch from the upper incisors. There was difficulty in removing the head of the bone in consequence of the large growth of new bone around it. She could now open the jaw an inch and a-quarter. Before operation the affected side was much atrophied, and the front of the jaw was rotated to that side. This condition was not benefited by the operation. In his second case the trouble had probably started in inflammation in the ear. The child was 8 years old, the lower jaw was atrophied, and the chin shifted to the diseased side. Since the operation two years ago the improvement was great, and she could separate the incisor teeth for an inch or more, whilst the joint was quite mobile. There was still deformity, however, as before the operation. In former days, before aepsis was attained, renewed ankylosis almost always followed the inflammation that ensued after the operation. No inflammation resulted nowadays, and the chance of subsequent movement was thereby greatly increased.

Mr. GODLEE inquired how much of the bone Mr. Lane took away.

Mr. LANE, in reply, said that two of the cases had been shown twice to the Society; one was still attending Great Ormond Street Hospital; the fourth was in Wales, and of that case he had a recent photograph. He had had a fifth case in which he had previously excised an elbow and a knee-joint.

SUDDEN DEATH DUE TO CARDIAC SYPHILOMA.

Sir DYCK DUCKWORTH related particulars of this case. T. W., aged 35, a strongly-built man, was walking in the street, carrying his little boy, on October 7th, 1894, when he suddenly fell down and expired. The body was carried to St. Bartholomew's Hospital, and was examined on October 9th. A very meagre antecedent history was obtained, which threw no light on the nature of the case. There was evidence of old syphilitic disease on the tongue and on the glans penis. A small gumma was found in the left lung. The heart weighed 22 ounces, and had firm adhesions to the pericardium, both at the apex and at the base. The right ventricle was hypertrophied and dilated; the valves were natural. The left ventricle was hypertrophied and dilated. There was a round depression in its wall above the apex, the diameter of a shilling, covered by long adhesions. This was due to a thinning of the wall, with much endocardial thickening. A large aneurysmal pouch was found behind the posterior cusp of the mitral valve. This appeared from without as a tumour growing from the base of the heart, completely covering the left auricle. Its walls were half an inch thick, and the pericardium was closely adherent over it. On section, the muscle was found to be replaced by tough fibrous tissue, with foci of gelatinous matter. The endocardium was greatly thickened and fibrous. Microscopic examination proved it to be gummatous in nature, with patches of caseation. The smaller arteries showed signs of endarteritis. These appearances indicated plainly a recently gummatous growth at the base of the left ventricle, and a similar but older one near the apex of that cavity. The fact of sudden death as a frequent occurrence in cases of this nature was alluded to. The author had collected particulars of 14 similar cases. Death occurred almost if not quite suddenly in 8 of these cases. The disease was rare in women, only 1 of the 14 having occurred in that sex. The mean age of all the patients was 32. Many of the cases appeared to have been previously devoid of urgent symptoms. In some there had been pericardial pain. Graver symptoms were to be expected when fibrotic changes followed on the evolution of the gummatous growths, and when they led to aneurysms of the ventricular walls. The valves were usually not involved, and hence murmurs were not to be met with as in the case of rheumatic endocarditis. The ventricles and their septum were the common sites of these growths. Tendency to fatal and sudden syncope was probably explicable by the fact that endarteritis affected the coronary arteries in part, and possibly by the occurrence of embolisms from

the softening contents of aneurysms into coronary arterial branches, the ventricular walls degenerating in consequence and becoming gradually intolerant of strain. The great object was to make an early diagnosis when possible, and to seek for syphilitic concomitants in cases where there were obvious cardiac symptoms and no signs of involvement of the valves. The treatment was to employ iodide of potassium in full doses.

Dr. SIDNEY PHILLIPS had collected the records of many of these cases. In one case, that of a gentleman, aged 55, who had had syphilis two years, death was quite sudden, the only premonitory symptom having been occasional pain at the chest, which was thought to be gastric and trivial. He returned to work against the advice of his doctor, sat down in his chair, and died suddenly. Other cases had been recorded at the Pathological Society. When there was opportunity of examining for previous symptoms they were usually found, although they might not be properly interpreted. The gummata were usually found near the apex of the left ventricle in the cases of sudden death. They often gave rise to aneurysm; in fact, except from injury, aneurysm of the heart was almost always due to syphiloma. A young soldier who had had syphilis for four years, died suddenly of cardiac aneurysm, the result of gumma of the heart. Syphilis might cause extreme dilatation and false hypertrophy of the heart.

Dr. HALE WHITE said that at Guy's a genuine gumma of the heart was rarely seen. Syphilitic fibroma, which might have been gummatous, was oftener found. Its usual situation was over the left ventricle and the septum. He doubted if one could differentiate between gumma and fibroma in any case until after treatment, when if very little improvement resulted one would class the case as a fibroma. Of 9 cases he had known, 6 died suddenly. Several had previous symptoms. Thus, 2 were out-patients—4 died suddenly in the street, and the other 3 were hospital in-patients. Consequently, if a syphilitic subject had cardiac symptoms not ascribable to any ordinary lesion it might be inferred that there was gumma or fibroma. About twenty years ago Dr. Fagge collected a series of such cases, and his results were practically the same.

Sir DYCE DUCKWORTH, in reply, mentioned a case in which with hypertrophy of the left ventricle there was inordinate cardiac action. The patients had usually had active syphilis within the last two years before death or recognition and treatment of the lesion. In a case he had recently attended, after three months' treatment with iodide of potassium the patient had lost many of the first symptoms.

TRAUMATIC DERANGEMENT OF THE KNEE-JOINT DUE APPARENTLY TO FRACTURE OF THE SPINE OF THE TIBIA.

Mr. A. E. BARKER read notes of a case for which an exploratory arthrotomy was done. The patient received the injury while in a mine in South Africa, and came home quite disabled. In walking, the knee was very insecure and inclined to give way inwards, which movement was accompanied by a sharp audible snap. The head of the tibia could be slipped backwards on the femur either by active or passive movement, but could only be replaced by hard pressing forwards. The nature of the injury seemed to be obscure, but it appeared possible that the spine of the tibia was broken off, or the posterior crucial ligament torn through. The patient being anxious for an exploratory operation and relief, which was only considered possible, Mr. Barker laid open the knee-joint by sawing across the patella, and found the crucial ligaments apparently intact. The spine of the tibia was found, however, to be marked at its base by a deep groove into which the handle of a scalpel could be laid, and having the appearance as if it had resulted from imperfect union of a fracture of the process. Nothing further was done. The wound healed perfectly *per primam*, and the limb was kept immobile for some months. When last seen, more than a year after operation, the patient had a useful limb, with none of the former abnormal movements. He was advised to be cautious in using it however.

Mr. EDGAR WILLETT inquired what proof there was that such tough, unyielding structures as the crucial ligaments contracted after opening of the joint and the irritation which thereon ensued.

Mr. GODLEE considered the case very uncommon. He had presented a similar case to the Pathological Society from a boy whose leg had been amputated after a crash. Then it was found that the spine of the tibia had been torn off, a lesion not before suspected. He had seen a somewhat similar case lately. A little woman fell upon getting off an omnibus, and hurt the knee-joint. The symptoms were much like those in Mr. Barker's case, except that there was no exaggeration of the power of rotation of the tibia. As Mr. Barker had not found much improvement from his operation, he (the speaker) devised an apparatus for this patient with which she could walk fairly well.

Mr. BARKER had seen this patient, but did not consider her to be as much disabled as was his own patient. He considered that if the synovial membrane covering the crucial ligaments were irritated, as by the opening of the joint, it became hyperemic, and that the ligaments, not being kept upon the stretch, accommodated themselves to the new surroundings, and afterwards when put upon the stretch might be found to have contracted to the position of non-strain. Whatever the exact result of the operation on the structures of the joint, the man was greatly benefited as to his walking powers.

MEDICAL SOCIETY OF LONDON.

Monday, October 14th, 1895.

Sir J. CRICHTON BROWNE, F.R.S., President, in the Chair.

PRESIDENT'S ADDRESS.

AFTER the business of the general meeting had been disposed of, the President elect, Sir J. CRICHTON BROWNE, F.R.S., was installed in the Presidential chair, and delivered his inaugural address, choosing for his subject, "The Generalization of Specialism." He alluded to the fact that the Medical Society had during the last few years included among its presidents representatives of several of the great specialities into which the profession, in its ever-growing heterogeneity, tended to divide. He thought the liberal spirit which characterised the policy of this most conservative of medical societies was one of its most admirable features, for it prevented that insulation of the specialists, which was a danger both ethically and scientifically, and the impoverishment of professional thought, which the withdrawal from its consideration of novel and minute observations must entail. Specialism at the present time was inevitable, for no one could train his senses or muscles to consummate expertness in the use of all the now multitudinous instruments of research and treatment. The great thing was to keep the special departments in touch with the main body of the profession, to see that they were conducted on rational lines, and that the departments of practice detached by specialism did not become refuges for empirics or imperfectly equipped practitioners. He pleaded with specialists of all types and varieties to avail themselves of the advantages which the Society offered. While himself proud of being a specialist, he was prouder still of belonging to a great and magnanimous profession, and, in respect of his speciality, he urged that it was hardly a speciality at all, or only in a very restricted sense. It was, indeed, almost coextensive with medical practice as a whole. He regretted that those who devoted themselves to medical psychology were often compelled to spread themselves far beyond medical practice, and to merge their professional capacity in non-scientific and comparatively mental avocations. He admitted, however, that the attempt to separate completely administration from treatment was not likely to prove successful on a large scale. He looked forward to the organisation of hospitals for the treatment of mental disease on the lines submitted to the London County Council by Mr. Brudenell Carter, where psychology could be studied and systematic investigation, teaching, and demonstration carried on. He insisted on the necessity for a just conception of the relation of body and mind, and he alluded *en passant* to the materialistic constructions placed on this relationship, convictions based on sensory stimulation being accorded more weight than was accorded to other classes of belief. He protested against the view that mind was to be regarded as simply a result of cerebral activity or chemical transforma-

tions in the nerve centres. The series of phenomena separating mind from matter stood apart, a neural process and a mental process having nothing in common, and the facts of consciousness were not explained by the facts of brain function—in fact, psychology was not merely a branch of mechanics, consequently mind could have no causal dependence on matter.

THE RADICAL CURE OF HYDROCELE BY EXCISION OF THE SAC.

Mr. O. B. LOCKWOOD showed a number of patients on whom he had successfully performed the operation of excision of the sac for the cure of hydrocele. He showed that the operation for cure by injection was followed by a very large percentage of failures, in addition to other objections to this operation, which he mentioned. He referred to the alternatives, and described the operation of complete aseptic excision of the parietal layer of the tunica vaginalis. He had done twenty-five of these operations, one being for hematocele. They were accompanied with hardly any pain and but slight inconvenience. One patient had subacute suppuration, due to the frequent escape of urine into his dressings. The subsequent history of sixteen of these patients had been obtained. All were cured of their hydroceles. Another patient operated upon in the same way was also cured. Two cases illustrating the modification required in congenital hydrocele and in chronic hydrocele associated with hernia were described. He concluded by advocating the more frequent excision of encysted hydroceles of the cord.

Mr. SWINFORD EDWARDS resorted to excision of the sac only in cases in which injection had failed to cure. He had been struck years ago by the large proportion of failures after injection at St. Bartholomew's, and he attributed this fact to the use of the ordinary tincture of iodine instead of the Edinburgh solution, which was twice as strong. He had on one occasion used a 1 grain to the ounce solution of perchloride of mercury on the person, and at the request of the patient, himself a medical man. The "result" had proved very satisfactory, the patient not having laid up for a single day, and the cure being permanent.

Mr. BRYANT asked what was the average duration of the treatment by operation. He admitted that the treatment was of value, but personally he had recourse to it only after injection had failed. He himself used a mixture of the liquor and the ordinary tincture of iodine. He had injected simple hot water in four cases, with the result of effecting an immediate cure in two cases; in the two others suppuration followed, but these also after free incision resulted in cure. His own plan was to cut away a portion of the sac wall, swabbing the membrane with a solution of chloride of zinc (20 or 30 grains to the ounce), and packing the cavity with iodoform gauze. He thought this was a simpler plan than that advocated by the author.

Mr. WALLIS had operated on the author's lines seven times during the last three years. After his first case, which recurred, he had adopted the practice of scraping the hypertrophied visceral layer, and the results had been uniformly successful. He had never used a drain.

Mr. BIDWELL pointed out that some patients objected to any operation which necessitated the administration of an anæsthetic, and for this reason he had injected in several cases. In two of them, however, he had been obliged to excise the sac subsequently. He had drained in his first case, but as orchitis followed he had not since made use of a drainage tube. He denied that the treatment by operation was more severe than that by injection; the latter always obliging the patient to "lay up" for a period of more than ten days. He asked whether the author had been able to ascertain the condition of the parts after recovery in any of his patients.

Mr. LOCKWOOD, in reply, insisted on the fact that the injection of iodine was a very painful proceeding, besides involving the risk of saddling the patient with an orchitis, etc. Moreover, the result was very uncertain. All the patients with one exception were well in ten days, and left the hospital in a fortnight. He thought the use of a drainage tube was a wise precaution to avoid the formation of hematoma, etc. He had not as yet been able to ascertain the condition of the parts after operation.

HUNTERIAN SOCIETY.

CHARTERS J. SYMONDS, M.S., F.R.C.S., President, in the Chair.

Wednesday, October 18th, 1895.

PRESIDENT'S ADDRESS.

THE PRESIDENT delivered a short address on the advisability or justifiability of explorative abdominal operations. His first postulate was that if we could feel sure that no serious additional risk was run by the patient through the operation, then it was not only advisable but practically imperative; this class of cases he illustrated by several examples of insuperable (by other means) obstruction. He next spoke of the possibility of serious risk brought on by operation, and this group he illustrated by a case of urgent symptoms induced by gut adherent to the abdominal parietes, in which rupture of the intestine during separation was unavoidable. A third group of abdominal operations he spoke of, namely, exploration with excision of a kidney, and he laid down the inflexible rule that no nephrectomy should be done unless the other kidney had been definitely examined and found healthy. Lastly, he urged the great responsibility physicians now accepted if they waited till the bacillus coli communis had gained a firm footing in the tissues of the patient outside the lumen of the gut.

THE INFECTIOUSNESS OF RHEUMATISM.

Mr. HUMPHREYS read a paper on this subject, in which he referred to the recent lectures by Dr. Newsholme on the subject, and to other writings. He then proceeded to give several illustrative cases in which skin affections, follicular tonsillitis of a somewhat special type, and acute rheumatism had seemed to him definitely to follow one another as if by infection, either in the same patient or in different members of the same household. He had taken careful notes of many such cases, and to him they seemed to point very strongly though, he admitted, by no means conclusively, to the specific bacillary nature of true rheumatism.

Dr. SHADWELL gave illustrative cases in which he traced rheumatism to drain poisoning, and to the unwashed blankets in which a case of rheumatic fever had lain. He felt prepared to accept the infectious nature of the malady.

Mr. STEVENS hoped to see the specific bacillus found by scientific workers.

Dr. HINGSTON FOX thought it difficult to accept the bacillary theory, but drew attention to the relation or likeness of the tissues affected by rheumatism. His mind leaned more towards a nervous origin for the disease; he quoted the historical case of the man who was cured of acute rheumatism by the shock of a railway accident.

Dr. LYON thought there was danger in accepting the bacillary view, in that it might lead men's minds too far from clinical causes, namely, lowering of vital activity of the body with exposure; that, in fact, it might draw all attention to the seed leaving the soil in a state of neglect.

Mr. J. T. FOX compared the possible bacillus to the malarial organism, and stated that though malaria, as a rule, rendered the patient liable to future attacks, there was at least one variety that rendered the patient the himself having experienced it immune against future malarial paroxysms.

Mr. HUMPHREYS, in reply, mentioned a case in which, from similar exposure to drain air, the husband caught typhoid fever and the wife acute rheumatism.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Thursday, October 10th, 1895.

ANNUAL GENERAL MEETING.—INSTALLATION OF PRESIDENT. DR. JAMES DRUMMOND, of South Shields, the newly-elected President, was introduced.

CASES.

Dr. WARDLE showed a patient on whom he had successfully operated for Diffuse Suppurative Peritonitis, due to disease of the appendix. The abdomen was drained of 2 quarts of pus and the appendix though seen was not removed on account of the condition of the patient. The drainage tube

was taken away at the end of 48 hours, and except for some fecal discharge through the tube opening on the sixth day healing was uninterrupted. Dr. Waddle thought that in such cases the tube might be removed earlier than had been taught. — Mr. RUTHERFORD MORISON showed some cases of Syphilis, and Mr. PAGE a case in which Epithelioma of the Penis and Inguinal Glands had been mistaken for a syphilitic lesion. — Dr. D. DRUMMOND showed a bricklayer, aged 48, who had been troubled with a cough for two years. The case was at first regarded as one of Phthisis Pulmonalis. During the last two months severe pain in the back, chest, and right arm had been the most prominent symptom, and still more recently an enlarged gland was discovered under the left jaw. The gland was now very hard and fixed, and this, together with the severe pain and other signs of a growth in the anterior mediastinum, made the diagnosis of malignant disease of the lung easy, though the long history and the physical signs at first proved misleading. Dr. Drummond also showed a neurotic man, aged 25, who had been lying in bed for five years and was reduced to a weight of 5 stone—a very good example of the condition known as Anorexia Nervosa. The patient, after a month of treatment, had gained a stone in weight and was walking about. For the first fortnight of his stay in hospital, however, he did no good, and not until the nurse was forcibly impressed with the need for getting him well did any improvement result. The case illustrated two things: (1) that a certain amount of compulsion must be used in such cases, and (2) that isolation was not essential. — Dr. HUME showed a boy of 14, along with a Tumour in the upper jaw which he had excised. Four years before the patient got a blow on his left cheek, which swelled immediately. The swelling soon became painless, but slowly increased, and was removed on September 2nd. Microscopically the tumour was a myeloid sarcoma. Dr. Hume also showed a man on whom he had successfully performed Nephrectomy for what he regarded as a rare condition. The man was a sea-going engineer, aged 25. Five years ago he had his leg amputated for an accident, and retention of urine, which followed, necessitated the use of a catheter. The catheter caused cystitis, and from this time he had urinary distress. Pain in the right kidney with pus in the urine suggested calculus, and the kidney was examined by drawing it out on the loin through the ordinary lumbar incision and palpating it; but it was neither incised nor punctured. Dr. Hume thought the danger of wound infection from puncturing even a healthy kidney was to be remembered. No calculus was discovered, and the kidney was returned. For some months the patient was no better and no worse. Then the pain became more severe, and at last a swelling was discovered in the loin, evidently an enlarged kidney. Nephrectomy was performed on July 15th, 1895, after which for a time the urine cleared of pus, and then there was some return. The patient's general condition was much improved. On section, the kidney was enlarged and studded with abscesses, and looked as if it might be tuberculous. The microscopist reported, however, that it was an example of ascending septic nephritis.

SPECIMENS.

The following specimens were exhibited:—Dr. WARPLE: A very large Gall Stone removed by cholecystotomy from a lady aged over 70. There was a history of frequent "spasms," but except for the absence of jaundice all the evidence was in favour of gall stones. After an attack threatening life cholecystotomy was performed. The gall bladder walls were very thin and firmly adherent to the stone, which had to be dissected out. Death followed from septic heart. — Dr. HUME: (1) A Myoma from the anterior vaginal wall of a middle-aged unmarried lady. Hemorrhage was severe, and frequent attacks of retention of urine called for the use of the catheter. The urethra was so elongated and tortuous that considerable difficulty was experienced with the catheter, and on one occasion the bladder had to be aspirated. The growth projected from the vulva, protruded the urinary meatus, and filled the whole vagina. It was enucleated after division of the vaginal wall, and the bleeding, which was severe, was arrested by tampon. Dr. Hume could find no such growth described as a fibro-myoma of the vaginal wall. (2) An Inverted Uterus removed by Vaginal Hysterectomy.

The inversion followed confinement four years before. Packing with iodoform gauze and a trial of different forms of elastic pressure were ineffectually tried before hysterectomy was performed. The patient made a good recovery. — Dr. MURPHY: (1) A Tongue excised for Epithelioma from a woman. The sex of the patient was of interest. (2) A Pessary of India-rubber, filthy and corrugated, which had lain for years in the vagina of a patient supposed to be suffering from cancer. (3) An Enlarged and Cystic Ovary and a Normal Ovary and Tube which he had taken from a patient without a vagina, and with a nodule only to represent the uterus, who had suffered severely from abdominal pains. — Dr. D. DRUMMOND: (1) Congenital Cystic Kidneys taken from an adult. The case was correctly interpreted during life from the presence of anemia and of symmetrical swellings of long duration in the renal region. The specimens were beautiful examples of the condition. (2) An Aneurysm of the Aorta which had pressed upon and obstructed the right bronchus. He had shown the patient at a previous meeting, and now exhibited the specimen obtained post mortem, for in connection with it he had described what he ventured to call a new physical sign: The respiration was stertorous, and all over both lungs rhonchi were to be heard. Over the right lung inspiration was loud and accompanied by rhonchi as over the left, but in the right lung expiratory sounds were absent. That this was due to pressure on the right bronchus the specimen exhibited made certain.

BRITISH ORTHOPÆDIC SOCIETY.—At the last meeting of this Society Mr. NOBLE SMITH showed a case of complete recovery from Compression Paraplegia in which laminectomy had been performed. He also showed specimens, amongst them a portion of the Vertebral Column of an infant who had suffered from spinal caries and general tuberculosis. — Mr. ROBERT JONES brought forward specimens showing chronic Hypertrophy of the Fingers in a child aged 18 months. From microscopic specimens the overgrowth seemed to be fatty, and not lymphatic in nature. He also exhibited three photographs of cases of Fracture of the Great Trochanter, in which the ultimate results had been very good. — Mr. NEWHOLZ showed photographs of a case of Genu Recurvatum in a child. By forcible traction and flexion at intervals, combined with an anterior angular splint, the limb was brought into the improved position illustrated. — Mr. LUKE FRANKER brought forward a patient, aged 7, on whom he had operated for most pronounced Congenital Talipes Equinovarus. The deformity was completely rectified by appropriate tenotomies, massage, and manipulations. — Mr. J. JACKSON CLARKE demonstrated specimens of Spina Bifida Occulta, Double Congenital Dislocation of the Hip, Congenital Talipes Equinovarus, and Atro-Axoid Disease. — Dr. N. GRATTAN exhibited his improved Osteoclast, and stated that he had done about 220 cases with it, and never lost one. — Mr. A. H. TUNNEY communicated a paper on (1) Observations on the Union of Tendon, with their Practical Bearings. Messrs. JACKSON CLARKE and MUIRHEAD LITTLE followed with remarks. — A discussion on the Treatment of Abscess in Pott's Disease was initiated by a paper read by Mr. TUNNEY, and Messrs. ROBERT JONES, E. MUIRHEAD LITTLE, J. JACKSON CLARKE, and LUKE FRANKER took part in it.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A clinical meeting of this Society was held at the Wandsworth and Clapham Union Infirmary on October 9th; Dr. GILBERT RICHARDSON (President) in the chair. — Dr. BERNARD NEAL, the Medical Superintendent of the Infirmary, showed the following cases: (1) Sarcoma of Axilla in a man, aged 44, following the removal of a warty growth from the wrist a year ago. (2) Progressive Muscular Atrophy in a man aged 61. (3) A case of old-standing Inguinal Hernia in a man aged 61, in which symptoms of strangulation came on within half an hour after the prolapse of the hernia. Failing reduction, and owing to the man's condition becoming rapidly more urgent, operation was performed in two hours with a successful result. (4) Chronic Rheumatoid Arthritis in a woman aged 28, accompanied by vaginal discharge of doubtful character. (5) A case of Foul Ulcer dependent upon diseased metatarsal bone, which was successfully excised, leaving only a small sinus. (6) Two cases of Senile Scirrhous of Breast.—A hearty vote of

thanks was passed to Dr. Neal for his courtesy and hospitality.

READING PATHOLOGICAL SOCIETY.—The fifty-fourth annual meeting of this Society was held on October 10th, in the Library of the Royal Berks Hospital, Mr. OLIVER C. MAURICE, the President, being in the chair, and about forty members attending.—Dr. STEPHEN MACKENZIE delivered the inaugural address on The Advantage to be Derived from the Study of Dermatology. He said the study of diseases of the skin afforded one of the best fields for educating the observant faculties and training the mind to discern the phenomena of disease and for watching the effects of remedies. Nowhere else, with the exception of the visible mucous membranes, could they observe the whole pathological processes so well. He described the skin physiologically, and the influences affecting it, and then dealt with the many diseases to which the epidermis was liable, and their treatment. Among his conclusions were that many skin diseases generally believed to be constitutional were traceable to bacteria, and that very few skin diseases were directly traceable to dietetic causes, though improper diet might largely aggravate existing eruptions, so that the avoidance of alcohol, the regulation of the bowels, and the cure of anaemia were of infinitely more importance in treatment than diet, and at the same time the disease must be cured by external means. The golden rule to preserve a healthy skin, as to avoid other ills, was to observe regularity, moderation and temperance in matters of eating and drinking, especially as regarded alcohol.—The annual dinner was held at the Queen's Hotel, under the presidency of Mr. MAURICE.

WIGAN MEDICAL SOCIETY.—A meeting of this Society was held on October 3rd, when a good number of members and several visitors from Preston and St. Helens were present. Mr. WM. M. ROODROFF (President) occupied the chair.—Dr. T. HARRIS, Physician to the Royal Infirmary, Manchester, read a paper on the Clinical Value of Inoculative Experiments in Guinea-pigs in the Diagnosis of Tuberculous Phthisis. He referred to the difficulty which existed in diagnosing between some cases of simple chronic pneumonia of a non-tuberculous nature, and chronic tuberculous fibroid phthisis. He brought forward a series of cases which he had met with during the past two years, in which the sputum had been repeatedly examined by himself and others for tubercle bacilli with negative results, and the sputum from these cases he had inoculated into guinea-pigs without producing tuberculosis. He also referred to some cases in which the expectoration was foetid, and was due to bronchiectasis, and in which tubercle bacilli were absent from the sputum. The sputum from these cases, which had also been inoculated into the guinea-pigs, gave negative results. A third series consisted of cases of repeated examinations of the sputum from cases which had failed for a long time to show tubercle bacilli, but where after a number of examinations had been made a few of the organisms were discovered. In all these latter cases the guinea-pigs which were inoculated with expectoration became tuberculous. The experiments were considered of value as check experiments where repeated examinations of sputum from doubtful cases of pulmonary disease failed to show the presence of tubercle bacilli, and they also confirmed the view that chronic fibroid disease of the lung usually left by an acute pneumonia does exist, and that such cases are of non-tuberculous nature.

BRADFORD MEDICO-SURGICAL SOCIETY.—At a meeting on October 8th, Dr. S. JOHNSTON, the retiring President, introduced Dr. ADOLPH BRONNER as the President for the coming year. The new President delivered an address on Otorrhoea, its Complications and their Treatment. Otorrhoea was the result of an inflammation of the mucous membrane of the middle ear, caused by micro-organisms passing up the Eustachian tube from the pharynx. Hence the importance of examining the throat in these cases. In children otorrhoea was very common, 85 per cent. being the result of one investigation. The principal complications of otorrhoea were: (1) Granulations; (2) Polypi; (3) Caries of the Ossicles; (4) Disease of the Attic of the Mastoid Antrum and of the Mastoid Cells.

Specimens were shown illustrating the treatment of these complications, and the different operations for mastoid diseases associated with the names of Schwartze, Macewen, Köster, Bergmann, and Stacke were described. (5) Brain Abscess, either Cerebral or Cerebellar. The symptoms were discussed, and Dr. Bronner detailed a case on which he had recently operated successfully. (6) Thrombosis of Lateral Sinus. (7) Meningitis. Many cases of local meningitis had been successfully treated by trephining and drainage. Cases were cited illustrating the different complications of middle ear disease, and the principal instruments used in the operations arising therefrom were exhibited. The conclusions the President directed attention to were: (1) The frequency of these diseases in infancy; (2) the necessity for operation; (3) the mastoid process should be carefully examined, and even if there were no external signs of disease, the operation should be done if symptoms were present; (4) the mastoid antrum should be opened before trephining.—Mr. MERCEUR read a paper on Venesection in a Case of Puerperal Eclampsia. On May 28th, 1895, he was called to see a lady in the eighth month of pregnancy. She was in convulsions, comatose, and dropsical. One-third of a grain of pilocarpin was given hypodermically; chloral and bromide by the rectum, and a tent introduced into the os uteri. Chloroform was administered later on, and delivery was accomplished by the aid of forceps; after delivery the fits returned, and were not controlled by treatment. The urine became solid on boiling. Venesection from the arm to 30 ounces was performed. The patient became conscious, had no more fits, and made an uninterrupted recovery. The President, Dr. GOYDER, Dr. BELL, and Dr. GRAY made remarks, and Mr. MERCEUR replied.—Mr. WILKINSON showed a man suffering from Lymphadenoma affecting the axillary, cervical, and inguinal glands.—Microscopical specimens were exhibited by Drs. MAJOR and CHAPMAN.

GLASGOW EASTERN MEDICAL SOCIETY.—This Society held its opening meeting on October 9th, when the following were appointed office-bearers for the ensuing year: *President*: Wm. Patrick, M.D. *Vice-President*: Alex. Patterson, M.D., F.F.P.S.G. *Treasurer*: Thos. McMurray, M.B. *Secretary*: Jas. Craig, L.R.O.P.E. *Editorial Secretary*: D. Couper, M.D. *Extra Councillors*: Geo. Mather, M.D., F.F.P.S.G.; Wm. Findlay, M.D.; Wm. Carr, M.B.; Robt. McC. Service, M.B.; Alexander Munro, M.B.; Jas. Dunlop, M.B.; John Wilson, M.B.

REVIEWS.

INDURATIVE MEDIASTINO-PERICARDITIS. By THOMAS HARRIS, M.D. Lond., F.R.C.P. London: Smith, Elder and Co. 1895. (Demy 8vo, pp. 67; 1 plate; 11 figures in text. 5s.)

Dr. T. HARRIS has done well to publish in a compact form the articles on "Indurative Mediastino-Pericarditis," which originally appeared in the *Medical Chronicle*.

The work may be divided into two parts. In the first three cases are recorded in such a way as clearly to bring out the clinical features and the pathology of the disease. The second part is devoted to a critical digest of our knowledge on indurative mediastino-pericarditis, and contains a table of twenty-five cases of the disease collected from various sources, with a useful bibliography.

The term "indurative mediastino-pericarditis," introduced by Kussmaul, is applied to two conditions, clinically indistinguishable, which differ in the extent and degree, but not in the kind of the anatomical lesions found. These are: (1) Adherent pericardium associated with the presence of much cicatricial inflammatory tissue in the mediastinum—indurative mediastino-pericarditis proper; and (2) adherent pericardium with some adhesions to the sternum, ribs, and lungs, but without any fibrosis of the mediastinum; this condition is pericarditis interna et externa.

Allied to these lesions, though of rare occurrence, is inflammatory thickening in the mediastinum, without any adhesions inside the pericardiac sac—chronic mediastinitis. These three conditions are illustrated by the author's cases. His statistics show that, contrary to the general impression, these lesions are rather commoner in adults than

in children, and that men are more often attacked than women.

The work is so full of thoughtful criticism and is so well planned, that it is to be regretted that it does not include the whole subject of adherent pericardium, on which a monograph is much wanted.

In conclusion, we confidently recommend this clear and graphic account of a somewhat obscure disease to all interested in the subject.

A. PHARMACOPEIA, INCLUDING THE OUTLINES OF MATERIA MEDICA AND THERAPEUTICS, FOR THE USE OF PRACTITIONERS AND STUDENTS OF VETERINARY MEDICINE. By the late RICHARD V. TUSON. Fifth Edition, edited by JAMES BAYNE, F.C.S. London: J. and A. Churchill. 1895. (Cr. 8vo, pp. 380. 7s. 6d.)

For a quarter of a century the late Professor R. V. Tuson's work has been the only *Pharmacopœia*, properly so-called, available for the veterinary student and practitioner. An effort has been made, with considerable success, to render the book more conformable with modern veterinary practice by the introduction of some of the newer drugs. The original arrangement with all its clearness is adhered to, and the statements are made with commendable brevity.

The work is not, however, free from defects. Formulae for several tinctures in common use are not given, although alluded to under the drug heading; enemas are formulated without indicating for which animals they are intended to be used; gentian is described as being used occasionally as a mild excitant and antiseptic externally; and the external application of decoctum tabaci is entirely ignored. It may be pointed out that an ounce twice daily of *massa digitalis composita* for chronic cough in the horse is very likely to lead to complications unless fuller information be afforded under the respective heads of "Use" and "Dose." No word of warning is given to the unsuspecting individual who may be preparing "a tow thoroughly saturated with a mixture of four parts of tar and one part of nitric acid" for a foot dressing. This mixture, if not prepared in the open air, is likely to asphyxiate the operator with its orange-brown fumes, and create considerable mess by its fierce boiling over.

Under the head of "Actions and Uses" occur many statements which require most rigorous revision; they are based upon pathological knowledge and expression of twenty-five years ago, and are totally unsuited to the present day.

It is a pity that the present edition has been brought out without the collaboration throughout of some experienced veterinary therapist. The chemical and botanical sides of the work are handled in that thorough and correct manner which are indicative of Professor BAYNE's great knowledge of these special parts of the subject.

THE VALUE OF ELECTRICAL TREATMENT. By Dr. JULIUS ALTHAUS. London: Longmans and Co. 1895. (Demy 8vo, pp. 100. Four illustrations. 2s.)

This little book may be taken as a summary of Dr. ALTHAUS's views on medical electricity, a subject in which he has had an extended experience. The plan of the book consists mainly of brief accounts of representative cases under the headings of the different diseases for which electrical treatment has been found useful by the author. These are for the most part nervous disorders, but a few pages are devoted to other complaints. Electrolysis is also touched upon, in connection with its uses for the removal of warts, superfluous hairs, etc. A very interesting case of exophthalmic goitre is related, in which electrolytic destruction of part of the enlarged thyroid gland was followed by disappearance of the tumour and relief of the symptoms. This method of treating Graves's disease is likely to yield better results than can be expected from simple electrical treatment applied percutaneously. Although not supplying all the requirements of a beginner in medical electricity, Dr. Althaus's book will be read with pleasure and interest by those who have experience in the subject.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

COMPRESSED TABLETS.

We have received a number of specimens of compressed drugs sent by Messrs. Parke, Davis, and Co., manufacturing chemists, 451, Oxford Street, and 21, North Audley Street, W. These tablets are well made, and the excellence of the sugar-coated *casarea sagrada* and *pepsin aseptic tablets* is especially worthy of note; their solubility or disintegration in water also is perfectly satisfactory. Messrs. Parke, Davis, and Co. have anticipated the wants of medical practice by preparing compressed tablets of various formulae, such as *casarea grandiflora*, tincture of digitalis, and chlorate of caffeine, and citrate of caffeine as a heart tonic, and viturnum (black law) with other drugs as a uterine tonic. Tablets of the four chlorides from the University Hospital *Pharmacopœia*, and the hypophosphites of quinine, iron, manganese, etc., with beechwood creasote. Sodium salicylate, extract colchicum, and tinct. digitalis, and hydrastine hydrochlorate with lead acetate, zinc sulphate, and morphine acetate. Antiseptic solutions can be readily made from the tablets containing mercuric iodide or mercury chloride combined with chloride of ammonium or citric acid. *Casarea sagrada* extract can be given in a sugar-coated tablet or in the ordinary compressed form combined with aloin and podophyllin.

For preparing peptonised milk, etc., compressed tablets of pancreatin with sodium bicarbonate are convenient. An alkaline antiseptic nasal application can be made from the nasal tablets containing sodium bicarbonate, borate, chloride, benzoate, and salicylate with menthol, oil of eucalyptus, etc. Lactophenin, a new antipyretic, which is said to possess advantages over antipyrin and phenacetin, and ferratin, a new easily-absorbed iron preparation, are also made in a compressed form.

PEPTONE OF BEEF.

From a consideration of the results of analysis we are of opinion that the sample of the Liebig Company's Peptone of Beef submitted to us consisted of a true "peptone" of meat, and that it was well made and of very good quality. We find rather less total moisture than the amount put forward on the papers sent with the sample, the result being 22.1 per cent. against 30 per cent. stated. This is a point in favour of the manufacturers. The mineral constituents amounted to 8.23 per cent., and the organic extractive matters of meat, including peptones and soluble albumin bodies (albumoses) to 69.6 per cent. The total amount of these is stated by the makers to be from 57 to 67 per cent. The sample was free from objectionable chemical preservatives, and the peptone reactions are strongly given. We can, therefore, recommend Liebig Extract of Meat Company's Peptone of Beef as a very satisfactory preparation. It is very pleasant to the taste, and is of very good quality, containing 77.9 per cent. of total solid matters, 8.2 per cent. being mineral constituents, the solid matters, apart from the mineral matters, consisting of albumoses, peptones, and extractives.

THE Canadian Medical Association will hold its annual meeting for 1896 in Montreal. The President will be Dr. James Thorburn, and the General Secretary, Dr. F. N. G. Starr, both of Toronto. The Treasurer is Dr. H. B. Small, of Ottawa. The other officers are as follows, the first named being in each case a Vice-President and the second the Local Secretary: For Prince Edward Island: Dr. James Warburton; Dr. H. D. Johnson. For Nova Scotia: Dr. William Tobin; Dr. G. O. Jones. For New Brunswick: Dr. W. W. White; Dr. Wm. Christie. For Quebec: The Hon. D. Macell; Dr. J. G. McCarthy. For Ontario: Dr. Fife Fowler; Dr. J. H. Mathieson. For Manitoba: Dr. H. B. Crown; Dr. W. J. Neilson. For North-West Territory: Dr. G. Brett; Dr. G. Macdonald. For British Columbia: Dr. R. E. McKechnie; Dr. W. A. Richardson.

LITERARY NOTES.

The new periodical to be called *Pediatrics*, devoted to diseases of children, to which we have previously made reference, will make its first appearance on January 1st, 1896. It will be owned by Dr. Dillon Brown, of New York, and edited by Dr. George A. Carpenter, of London, and will appear twice a month. The first number is promised for January 1st next. It will be published in London by Messrs. John Bale and Son, and in New York by the Van Publishing Company. The annual subscription will be 8s.

The Queen, as Empress of India, has accepted the dedication of the Indian translation of Mr. S. Osborn's book *First Aid to the Injured*. The little work has also been translated into French, German, Italian, and Japanese.

Messrs. Swan Sonnenschein will shortly publish a work by Mrs. Mary Ann Scharlieb, M.D., entitled *A Woman's Words to Women*.

Mr. W. Heinemann announces the publication of a translation of Dr. William Hirsch's *Genius and Degeneration*, by Mr. J. R. Mollraith; and one of Dr. Oscar Hertwig's *Biological Problem of To-day*, by Mr. Chalmers Mitchell.

Among their forthcoming books, Messrs. E. Bentley and Son announce *My Residence at the Court of the Amir*, by John Alfred Gray, M.B., late surgeon to His Highness the Amir of Afghanistan.

Of new magazines, it may truly be said "the cry is still they come." The most recent arrival is *The Country House*. The first number, which is now before us, contains an interesting and varied assortment of papers, among which we may particularly mention "From Berkshire to Balmoral in my Caravan," by the indefatigable Dr. Gordon Stables, who, like Tennyson's brook, goes on for ever. A paper on "Making a Pasture," by the veteran Sir J. E. Lawes, will interest the agriculturist; and there are stories by the Rev. S. Baring Gould and John Strange Winter, with chatty articles on various subjects for the general reader. The illustrations are plentiful, without undue encroachment on reading matter.

The October number of *Scribner's Magazine* contains an article on Huxley by Mr. George W. Smalley, who, however, has little original to say about the great apostle of science except that he gave dinners to which Mr. Smalley, with other distinguished men, was occasionally invited, and that he was fond of cats, a taste which, as one gathers, is shared by Mr. Smalley. We learn incidentally that Huxley "liked to think of himself as the heir of all the ages," and that he also "liked his pipe, and would never admit that tobacco in moderation could hurt anybody;" that he would "dine on a little soup and a bit of fish;" that he "used the chest notes" in lecturing, and that once he confided to Mr. Smalley that if he were not a man he should like to be a tug. Mr. Smalley seems to think some kind of apology is expected of him for the fact that Huxley allowed himself to be made a Privy Councillor. "It need not" (he kindly explains), "be thought that Mr. Huxley derogated in accepting it, whatever incongruity there might seem to be between his proud plebeianism and the title of Right Honourable by which henceforth he was to be called." This from a writer in a country where it seems to be the aim of every citizen to disguise his "proud plebeianism" under a military or official title of some kind is amusing. Mr. Smalley approves of Huxley's style, but he somewhat disablers his own judgment in the matter by pronouncing that Darwin, the most lucid and one of the most graceful of scientific writers, "had a very bad style," and that Tyndall, who from a purely literary point of view was nothing but sounding brass or a tinkling cymbal, "wrote admirably." Altogether Mr. Smalley's article, though readable enough, is a chronicle of very small beer.

In a work entitled *Los Indios, su Historia y Civilización*, by Don Antonio Batres Jáuregui, a well-known writer on Guatemala, some interesting information is given as to the medicine of the natives of America at the time of its discovery by Columbus. They were acquainted with the therapeutic properties of balsam of Peru, jalap, rhubarb, sarsaparilla, and coca. The aborigines used pills made of the living flesh of the lizard called by them "cietz palin" (*Lacerta terrestris*), which they looked upon as a specific for

cancer, leprosy, and syphilis. From maize they made various preparations which are still largely used in Guatemala and elsewhere as beverages, and mixed with sarsaparilla, gualacum, etc., as remedies for venereal and other diseases. According to Señor Batres Jáuregui, the aborigines of Guatemala had some knowledge of elementary surgery, and could reduce dislocations, set broken bones, extirpate tumours, and treat wounds with medicinal lotions and herbs. They could also embalm dead bodies. They made great use of baths—cold, luke-warm, and hot—in various diseased conditions. The *termacal*, a primitive kind of Turkish bath, was employed by them from the earliest period.

ENTRIES OF THE MEDICAL SCHOOLS AND COLLEGES.

We are indebted to the Deans, Wardens, or other officers of the medical schools and colleges in England for returns of the number of new students who have commenced the study of medicine, or have entered for special courses in the several institutions. From these returns the following table has been compiled. The returns may probably call for some amendment subsequently, but they may be taken to show with approximate accuracy the numbers of new students at the schools and colleges from which they have been received.

	A.	B.	C.	D.	E.
St. Bartholomew's Hospital	174	36	28	20	167
Charing Cross Hospital	17	36	28	20	83

* No return received. † Including Bacteriology. ‡ Figures not yet available.

- A. Number of students who have joined for the full curriculum.
- B. Number of students who have joined for special courses.
- C. Number of dental students.
- D. Number of students who have joined classes for preliminary instruction.
- E. Total, excluding students who have joined classes for preliminary scientific instruction.

The returns given above from the metropolitan medical schools indicate a slight improvement upon the low number of last year. The total number of new students entered for the full curriculum (excluding the London School of Medicine for Women) is 581, as compared with 552 in 1894.

Looking back to similar tables published in previous years, we find that the average number of new students entering the metropolitan medical schools yearly for the five years 1881-85 was 535, for the five years 1886-90 was 646, and for the last quinquenniad (1891-95) 598. The average entry during the last five years is thus seen to be below the average of the two previous quinquennads, and the actual entry this year below the average for the quinquenniad.

The returns from the provincial medical schools and colleges are as yet too incomplete to warrant any deductions.

We have received a bound copy of the *Practitioner*, January to June, 1895, forming a handsome and handy volume with a very full index. We congratulate the new editor, Mr. Malcolm Morris, on the success of his efforts, which have made the *Practitioner* one of the most useful and certainly the most readable medical "monthly" now in existence.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, OCTOBER 19th, 1895.

THE PARLIAMENTARY COMMITTEE ON ADULTERATION.¹

II.

Among the suggestions made to the "Food Products Adulteration" Committee of the House of Commons for the amendment of the law relating to adulteration, one of the more important and valuable was the proposed establishment of a Board of Reference or Council of Control, whose duty it should be to lay down definite and clear rules for the guidance of public authorities and their officers in the administration of the Adulteration Acts; to fix and vary standards of purity and strength, to lay down definitions as to the composition and characters which different foods and drugs should possess, to decide upon what constitutes adulteration, to give a final decision in matters of dispute, and to discharge such other functions of a similar kind which might be considered necessary to secure the uniform and equitable application of the law throughout the country. Although differing in minor particulars, this suggestion—originally made in the draft Bill prepared by the Council of the Society of Public Analysts—was put forward, in effect, by four representative witnesses whose general acquaintance with the subject, and whose responsible positions, should lend considerable weight to their statements before the Committee. We refer to Mr. Charles Umney, representing the general body of wholesale druggists, and the Chemical and Drug Section of the London Chamber of Commerce; to Mr. John Rogers, another representative of the Chamber, as well as of one of the most important wholesale trading houses in London; and to Mr. R. A. Robinson and the Hon. A. de Tatton Egerton, M.P., respectively chairmen of the Adulteration Acts Committees of the London municipalities of Kensington and St. George Hanover Square, where, for several years, the existing Acts have been administered with vigour and success.

Of the principle of establishing a Central Board of Control we heartily approve, so long as it is carried out upon broad lines, which will prevent the vesting of the ultimate control in the hands of a single Government department; or, what is still worse, in the hands of a single Government official, bound down by red tape, and in all probability out of touch with the daily progress of analytical science and with the

general body of public analysts. A centralisation of this description would be unquestionably an unmixed evil; but the institution of some system whereby the law will be administered in a uniform and equitable manner is obviously an urgent necessity, and it is no less necessary that by some such system the heavy and unjust responsibility of settling what is, and what is not, to constitute adulteration and fraudulent dealing in reference to a great variety of commodities, should be removed from the shoulders of individual scientific officers, scattered all over the country, and compelled to act upon their own initiative. The present system—if the term can be used—is exceedingly unsatisfactory, and it is astonishing that with such cumbersome machinery so much real good has been done. Leaving other matters for the moment, the present system of reference, whereby a portion of a sample alleged to be adulterated can be sent to the Somerset House Laboratory for examination, results in producing a ludicrously unsatisfactory state of things, and in reducing the administration of the Acts in many cases to a farce. With respect to milk, for instance, it has been proved to demonstration that a purchaser of ordinary milk is entitled to get not less than 3.5 per cent. of fat in it, and if any further proof were required, it is afforded by the fact that the better class members of the milk trade, and the representatives of large dairy companies, before the Parliamentary Committee and elsewhere, have advocated the fixing of a higher standard of quality in regard to fat than 3 per cent. Even such a body as the Metropolitan Dairy-men's Society, whose conclusions must be considerably influenced by the feelings of the smaller dealers, have recently advocated a standard of at least 3 per cent., and have done so in a way that amounts to an admission that the standard should really be fixed at a higher percentage. In the columns of the *BRITISH MEDICAL JOURNAL* we have recently shown how the adoption of an exceedingly low standard such as 3 per cent. leads to widespread fraud. Thousands of analyses have been published showing the limits between which the composition of really genuine milk varies, and yet the Somerset House analyst, as it appears from published legal cases and from the evidence given before the Committee, adopts the universal limit of 2.75 per cent., a limit which can only be founded upon the analyses of the miserable products yielded by improperly fed, improperly kept, badly managed, or very abnormal single animals, which products cannot be called "milk." Even this limit, it would seem, is not adhered to, since in a recent case, Mr. Bannister of Somerset House, declined to support a certificate of the Middlesex County Analyst alleging fat abstraction, because he found some 2.6 per cent. of fat. These circumstances, in connection with a food product so universally important as milk, will serve to show the necessity for establishing such a Board as that which has been suggested, apart from any other considerations. The injury that is done by such a state of things is incalculable.

Inasmuch as the Council of the Society of Public Analysts has itself suggested the appointment of a Board of Control, it cannot be supposed that to do so would be to cast a slur upon these officials. Indeed the more responsible witnesses who appeared before the Committee paid a tribute to the general excellence of the work done

¹ The first article was published in the *BRITISH MEDICAL JOURNAL* of September 26th.

by the public analysts. "With very imperfect means," observed Mr. Rogers, "they have done wonders," while Mr. Umney and others expressed in decided terms a general approval of their scientific and official work, and of the fairness with which their duties had, in the main, been discharged. The establishment of a Board of General Control would not mean the abrogation of the individuality of the public analyst, nor the reduction of his work to mere mechanical routine. In the draft Bill previously alluded to it is suggested that the proposed Board should consist of the chief chemical officer of the Inland Revenue Department, of three public analysts nominated by the Local Government Board, and of two additional members nominated by the General Medical Council and the Board of Agriculture respectively. Mr. Umney very reasonably suggested nominees of the Institute of Chemistry, of the Pharmaceutical Society, and of the London Chamber of Commerce; while another witness considered that an elected advisory council of traders would be able to render most valuable assistance to the Board of Reference or Control when established—a proposition which is no doubt worthy of careful consideration; but the acceptance of the main principle, apart from details, is the point of importance at present.

The report recommends that the Food Products Adulteration Committee should be reappointed in the forthcoming session. It is earnestly to be hoped that this will be done, as a great variety of important matters have still to be dealt with and much valuable evidence remains to be given. The extent to which the Acts should be applied, the most effective steps to be taken to ensure the adequate carrying out of the law in districts where the authorities neglect their duties, the question of minimum penalties, and especially the best way of dealing with the wholesale producer and vendor of adulterated goods and of protecting the innocent retailer—in regard to which we think the most effectual course would be to make the wholesale dealer a co-defendant in every case—are all matters which have engaged the attention of the Committee but which have yet to be considered far more fully and carefully. It is probable that most of the members of the Committee had but an imperfect conception of the magnitude of the work upon which they were called upon to enter, but in view of what has already been published the new Committee will necessarily appreciate the matter more clearly. It is to be hoped that, considering its gravity and urgency, the members who may be appointed will not shrink from the task, and that we may look for amending legislation of a comprehensive, just, and effective character.

CONCERNING ALCOHOL.

THE National Temperance Congress, a body which would be more properly called the Congress of Total Abstiners, held its meeting recently at Chester, as was briefly recorded in the BRITISH MEDICAL JOURNAL of October 12th. The papers consisted of the old arguments and appeals to which we are so well accustomed, and it is difficult to find any new matter in the reports of them.

We are far from wishing to imply that the absence of novelty is any reason against the holding of the Congress, or of the reading of these papers; on the contrary, the very persistence of the repetition of the old arguments may, by

its continual dropping, have more influence upon the dull public than more fluctuating if more adventurous doctrines. It is difficult to estimate our debt to these ardent enthusiasts who, by persistently hammering in their main doctrine, do no doubt produce an impression upon the masses. This achievement—one in which the more cautious and more sceptical methods of the man of science would assuredly fail, or which, at any rate, he would attain very slowly—is a service for which we cannot be too grateful.

Perhaps no man has deserved better of his country than the President (Sir B. W. Richardson), who adds to his somewhat rigid enthusiasm scientific attainments which command the respect of his opponents, if he has any, and a vein of common sense and knowledge of human nature which are very useful in the chair which he now occupies.

To ordinary readers the utterances, even of the more scientific of the speakers suffer from the "cocksureness" which arouses a continual mistrust, and leads us to suspect that, as science, their assertions are not worth all that their authors claim for them. It is of the essence of scientific truth that the searcher after such truth shall approach the study of natural phenomena with a single and unbiassed judgment; whereas it is but too apparent that the total abstinence lecturer is disposed to seize upon such parts of current doctrine as are suitable to his purpose, and has little disposition to weigh those parts which seem against him. As advocates this way of dealing with truth is fair enough; we shall wait to reform our fellow creatures for ever if we wait till scientific men work out a solid and coherent system of doctrine for us. Still, it would be more fitting if the speakers did not claim so loudly a scientific character for matter which is rather of the nature of counsel and exhortation than of scientific discovery or even of teaching.

One paper—that by Dr. McDowell Cosgrave—discussed a subject of some novelty and of no little scientific interest. It dealt with recent observations upon the organs of special sense, which appear to prove that alcohol acts from the first as a narcotic—that there is no previous stage of stimulation. This is in accordance with the general impressions of many persons accustomed to observe with care, who have been led to suspect that the so-called exhilarating effects of alcohol are apparent only, and may be explained by the suppression of the upper planes of the nervous structures with a consequent letting go of those below them. If this be so the exhilaration is not direct but indirect, and due to the sudden reduction from the careful thoughtfulness of the man to the careless buoyancy of the youth. This is not of course any final argument against the use of the drug. On the contrary, it might be alleged that the relief given by throwing the higher parts of the nervous system out of gear and leaning for a time upon the more automatic structures has a restorative value. It is evident, however, that any relief of this sort may be very dearly bought; and in any case should be confined within the narrowest limits.

Herein lies a problem which the more thoughtful among the abstainers will do well to work out. What the abominable "moderate man" alleges is not that he works better when he takes alcohol during his work—this delusion has been well insisted upon in the Congress—but that after work a small dose of alcohol with the last meal conduces to a cheerfulness and to a forgetfulness of the little worries of

the day, which promote digestion, brighten social life, and lead to a pleasant repose.

A weary man who returns home from a hard day, with his head full of the cares of the day, brooding over this man's rudeness and that man's folly, and then, by whatever mechanism, chases away these thoughts, comes into amity with all men, and expands in the bosom of his family instead of wearily sulking, may live more happily and sleep better for his glass of wine.

It is this relief which the ordinary man is unwilling to give up so long as he has full control over his appetites, and is not sure that he is doing any harm by this apparently useful custom; such points seem to us to demand a little more care and investigation. On the other hand, to threaten us with the penalties for "breaking the laws of Nature"—as if the "laws" of Nature could be broken, or were rules imposed by some authority from without—and again to clamour for civil laws to prevent marriages between persons in whom any taint of insanity may be found, and so forth, is time less well spent because the limitations of practical politics are thus ignored.

METROPOLITAN WATER SUPPLY.

THE recent "inquiry directed by the Local Government Board into the cause of the failure of the East London water supply in the summer of 1895" seems to have reopened the subject of the adequacy "in quantity and quality for the water supply of the metropolis," which was inquired into by the Royal Commission presided over by Lord Balfour of Burleigh in 1892, which reported on September 8th, 1893. During the course of the inquiry, the purity of the water derived from the Lee has been impugned on the ground that the recommendations of the Royal Commission had been disregarded. Reference was made also to the well-known evidence quoted in paragraph 175 of this report; and although the East London Water Company did not put any witness into the box in respect of purity (and probably wisely, too), still we are face to face with the fact that "the state of matters" which, to quote the report, "ought to be remedied without delay," still remains unremedied, and are the same this day as those present on the day when the late Mr. Justice Watkin Williams pronounced what we, with all respect, venture to call his ill-advised judgment in 1894 *re* Hertford. It is a curious fact, however, and to this the Royal Commissioners bear testimony, that "the water as supplied to the consumer in London is of a very high standard of excellence and of purity" (para. 176). They refer to the prejudice against the use of river water, but state that no danger exists "provided that there is adequate storage, and that the water is efficiently filtered before delivery to the consumers."

It is precisely this "adequate storage" which the East London Company are now endeavouring to obtain, perhaps a first instalment towards carrying out the recommendations of the Commissioners.

The East London Company is entitled to draw—and to quote from the evidence of the Company's engineer does draw—10,000,000 gallons daily from the Thames; this, naturally enough, gives that company interest in the quality of Thames water, and we should like to know something more than we do at the moment as to the course taken by the

Thames Conservators towards preserving the purity of that river. Looking to the evidence of the officials of the Conservancy before Lord Balfour's Commission we find, as it seems to us, that a mere modicum of time is given to protecting the water from pollution, and that the inspectors have "river work proper" to attend to which absorbs much of the time which might be spent in detecting or remedying pollution.

We are, however, writing from the evidence given, and know that this practice existed when the area under charge of the Conservators was only a belt of country ten miles wide on each side of the main river. Perhaps, since the whole watershed is now in charge of the Conservators by the Thames Conservancy Act, 1894, 57 and 58 Vict., these mixed duties may be abolished; but there does not appear to be any provision in the Act for separating such duties, nor for a special fund for prevention of pollution. For this last purpose surely was the area extended, and the large extra contributions of the water companies permitted.

There does not appear to be a special officer detailed to the charge of this special duty with a proper and sufficient staff as we hoped to have seen. Last year advertisements appeared for certain inspectors who were to be paid the magnificent sum of £120 a year each. There were to be seven of them, and seven sub-inspectors at £80 a year each, to work under a committee. Whether such inspectors were appointed or not does not appear, nor has there been any public statement as to the success of the proposed committee.

It seems to be the fashion of the period to govern by committees, or Boards. The army itself is to be so "worked," we hear, at no very remote date; and we have some recollection of the saying of a distinguished legislator that if the Children of Israel had in their passage through the wilderness been under the command of a committee instead of a leader they would probably be wandering about the desert at the present day.

To carry out the requirements of an Act of Parliament in respect of abatement of pollutions needs individual action and diplomacy not usually found in those whose duty it is merely to find out an error and report it. To let such report be followed out by cumbrous machinery of notices and correspondence, the natural consequences of such procedure, makes the offender resentful and he, or the local authority, fights the matter to the bitter end, with, it may be, as in the case of Hertford and the East London water, a result that a pollution is legalised by a judgment of the High Court giving a peg on which to hang a complaint, as in the inquiry into the failure of the East London water supply.

THE WAR OFFICE AND "PRIVILEGED" COMMUNICATIONS.

In a recent review of the late Sir Thomas Longmore's work on *Gunshot Injuries*, which appeared in these columns (page 840), occurs the following sentence: "For a standard work of this kind it is regrettable that the author had not been able to gain access to reliable statistical facts, if such are available, regarding our more recent expeditions, such as those in Egypt, Burmah, Chin Lushai, Hazara, and Waziristan, in which weapons of greater range and velocity were employed."

These would have been of incalculable value, but possibly our War Office has been unable to furnish them."

The reasonableness of that criticism has been verified by the fact which has since come to our knowledge, that a medical officer has been reprimanded for publishing, without permission, in our columns some observations on the character of the wounds inflicted by small-bore weapons in the Chitral campaign.

That contribution was not only valuable, but most opportune towards the solution of a problem at present exercising military surgeons both at home and abroad; nevertheless, it has brought the writer into trouble, because it is officially declared that the subject is "privileged." We may be sorry, but cannot complain, if he unwittingly infringed a perhaps wholesome regulation, and thereby incurred censure; but we do complain of the somewhat dog-in-the-manger policy of both the home and Indian military authorities in such matters; they neither publish such "privileged" matter themselves, nor allow others to do so; or, if they do publish, it is generally long after the event, when interest has waned or the observations have even become obsolete. They manage these things better in the navy, of which the surgeons habitually forward papers for publication in our columns through their Director-General. We should like to see the same system adopted in the army, whereby such interesting observations as that to which we refer could be published to the profession at once through the medium of a medical journal. If there are objections to this course, let them be publicly stated, and then we may find arguments to meet them.

Another instance has recently come under our notice in which a medical officer has been requested to withdraw a paper dealing with an important point in connection with the new rifles and the wounds they produce. The matter is one of public as well as of scientific interest. As we have already pointed out in these columns, there is grave reason to doubt whether the new rifle is a suitable weapon to place in the hands of an expeditionary force against savage tribes. The question is, Will it stop a rush? The mere fact that the answer is in doubt ought, the plain man would be disposed to think, be in itself sufficient to cause the military authorities to be anxious to encourage the early publication of trustworthy information gathered by medical officers during recent wars. The disposition to repress scientific enthusiasm displayed by some military authorities is utterly contrary to the best traditions of the medical profession, and contrary also, as seems obvious in this case at least, to public policy.

Dr. Duclaux has been appointed Director of the Pasteur Institute, and Dr. Roux Sub-Director.

We are glad to see that the reports on the Irish workhouses which we are publishing are being reproduced in most of the Irish journals.

The Lord Chancellor has appointed Mr. George Harold Urmon, Secretary to the Commissioners in Lunacy, to be a Commissioner in Lunacy in the place of Mr. Charles Palmer Phillips, deceased.

The introductory address by the new President of the Clinical Society, Dr. Buzzard, postponed owing to his unavoidable absence from the meeting on October 11th, will be delivered at the meeting on Friday, October 25th.

The first Hunterian Society's lecture for the present season will be given on Wednesday, October 23rd, at 8.30 p.m., by Dr. Sims Woodhead. The subject of the lecture will be *The Probable Limitations of Serumtherapy*. Any member of the medical profession will be welcomed.

The Institute of France will celebrate its centenary on October 23rd, 24th, 25th, and 26th, with receptions, banquets, etc., ending off with a visit to Chantilly, where the members will be received by the Duc d'Aumale. The centenary will be made the occasion for the last obsequies to the most distinguished member of the French Institute, who has recently passed away. The remains of M. Pasteur, which have been temporarily placed in a vault in Notre Dame, will be finally interred on October 23rd. Sir Joseph Lister and other distinguished representatives of English medicine and science are expected to be present.

The staff of the Ophthalmological Department of the Edinburgh Royal Infirmary is now constituted as follows:—Dr. Argyll Robertson, whose term of office as Senior Surgeon-Oculist expired on September 1st, has been appointed Extra-Surgeon Oculist for one year; Dr. George A. Berry, who has held the office of Junior Surgeon-Oculist, has been promoted Senior Surgeon-Oculist, retaining half the beds in the department; Dr. George Mackay, the Senior Assistant, has been promoted to be Surgeon-Oculist with a certain number of beds; Dr. William G. Sym has become Senior Assistant, while Dr. Ernest E. Maddox has been appointed Junior Assistant Ophthalmic Surgeon.

THE "INDEX MEDICUS."

Dr. BILLINGS announces that up to September 24th he had received the names of 105 subscribers to the *Index Medicus*. The Medical Department of the United States Army subscribes 250 dollars (£50), the Library of the Surgeon-General's Office, Washington, 50 dollars (£10), and the British Medical Association has promised a similar amount. The subscriptions already promised amount to over £400.

THE NEW COMMANDER-IN-CHIEF AND THE ARMY MEDICAL DEPARTMENT.

Our contemporary, the *Pall Mall Gazette*, in its "Service Notes" refers to rumours, "as might have been expected," of impending "root and branch organisation of the Army Medical Service at the hands of the new Commander-in-Chief." Why "as might have been expected?" Had Lord Wolseley's intentions been long ago expressed before he anticipated reaching the position he is now to occupy? All we can say to the drastic changes spoken of is, that unless they meet with the concurrence of the department itself and the medical schools they are doomed to failure. There is no medical conscription to fall back upon, and if distasteful changes are arbitrarily forced on, the already ebbing flow of candidates will altogether cease, and the last state of the department be worse than the first.

THE HOUSEMAID AND THE DUSTPAN.

To those who know the true inwardness of things the sight of a housemaid brushing a dusty carpet is suggestive of many evils. The death of Pasteur has reminded the world of what is constantly present in the thoughts of medical men—namely, that while micro-organisms are the great producers of disease, dust is the great carrier of micro-organisms. Now that we know these things, it is distressing to find how little our knowledge is put to practical use, and to see old customs still unchanged, old habits which we know to be destructive carried on, and to find the housemaid on her knees, with her brush and dustpan, stirring up dust to the detriment of everyone, and breathing germ-laden particles to her own destruction. It needs but a small amount of

common sense to see that if carpets must continue, a thing greatly to be deprecated, they should be rubbed with a damp cloth rather than brushed, and that if, in deference to prejudice, they must be brushed, this should be done by a covered American sweeper with plenty of damp tea leaves. Of all ways of removing dirt from a carpet the worst is by the use of the ordinary short brush, which involves the housemaid kneeling down in the midst of the dust which she so needlessly creates, and drawing it into her lungs with every breath. For ordinary household use something like linoleum, something which can be washed with a wet cloth every morning, would seem to be the best covering for floors; but if carpets must be, and if it is impossible to teach the present generation the evils of seeking present comfort at the expense of future risks, at least let us remember that carpets may be washed even where they lie; that, till the day of washing comes, a closed sweeper is far better than a brush, and that the worst form of brush is one with a short handle.

CISTERNS AND THE CONSTANT SERVICE.

The difficulty of adapting hygienic ideals to the hard conditions and pressing necessities of actual life was strikingly illustrated in the futile conclusion arrived at by the metropolitan medical officers of health recently met to discuss the question of the retention of cisterns under the constant service, and the restrictions to be placed on the use of such stored water. The fact is that we have to reconcile, or to effect a compromise, between a number of mutually incompatible propositions: for example, the contamination of water from public works takes place in a large proportion of instances in the domestic cistern, and the chief advantage of the constant service is that it furnishes a fresh and pure water at all times. But since no human ingenuity can absolutely provide against accidental interruptions of the supply, it is necessary for health and safety that some reserve be stored for feeding the small cisterns attached to water closets and kitchen boilers. Again, while no harm can result from the use of stored water for house cleaning, laundry work, and even personal ablution, the practice of receiving the company's water into, and drawing it from, a cistern exposed to any risk of contamination completely neutralises the advantages of the constant service (save for extinguishing fires), and that worst of all would be the use for dietetic purposes, albeit the more urgent, of water that had been long stored without renewal in a cistern reserved for emergencies only, as was proposed by Dr. Talbot, who has provisionally patented one, to be made of glazed stoneware, in the form of an inverted bee-hive with a draw-off tap at the apex, which he would have fixed independently of the usual connections with the rising main proper to the constant service. But we cannot see why it should not be like cisterns under the older system, so placed that the whole of the domestic supply should pass through it, since its form would preclude the accumulation of deposits.

ARE COLLIERS EXEMPT FROM CANCER?

Mr. T. Law Whew, of Ironbridge, whose labours to elucidate the cause of cancer are well known, in an interesting paper on this subject, states that he has practised for twenty-five years in a district overlying the Shropshire coal-field, and during that time he has been surgeon to two collieries, yet he has never seen a single case of cancerous disease in a collier who was working in the pits. "Moreover," he says, "an examination of the books of the district registrar shows that of all persons whose deaths are registered as due to malignant disease during the past thirty years, only two are described as 'coal miners.' Of these one I know positively had long retired from the arduous occupation of coal-getting, and had for many years followed the more gentlemanly occupation of rat-catching."

The other died in the workhouse, and had not worked in the pit for some time. It should be borne in mind that in this same locality cancer is very common, and is often seen amongst the furnacemen, moulders, ironworkers, and general labourers." Another practitioner living in the same district is also unable to recall the case of any collier suffering from cancer. The immunity, however, does not extend to sarcoma. The explanation lies partly: Mr. Webb thinks, in the habitual cleanliness of the collier who "tubs" daily as soon as he comes home from the pits, partly in the fact that his habits rarely lead him to drink water from casual sources. He goes to work early, and habitually in his working hours carries with him a quart can containing cold tea or coffee without milk. He always returns home to dinner, at which he usually drinks tea, or, if he can get it, small beer, whilst his supper consists of bread and cheese, with sometimes an onion and a pint of beer. The colliers in Shropshire are a temperate, peaceable, law-abiding class not given to excesses of any kind. Though they are often seriously injured in their dangerous occupation, they survive the most extensive wounds and fractures, and although they look pale and anemic they are in reality a healthy set of men. It would be extremely interesting if the surgeons who practise in the great coalfields of the North and in the South Wales colliery district would give their experience upon this point of the alleged unequal distribution of cancer mortality in the population of coal-mining districts. If it is a fact that men working underground and not drinking much water are more exempt from cancer than those in a similar state of life working above ground and drinking from casual water supplies, we shall have a more tangible reason for suspecting cancer to be a waterborne disease than is afforded by any of the present theories or statistics.

WITNESSES AND COURTS OF LAW.

At an inquest recently held at St. Clement's Vestry Hall before Mr. Troutbeck, on a man who fell off his cab and shortly afterwards expired, it appeared that a person who witnessed the occurrence declined to give his name and address, or to attend the inquest, on the ground that he did not want to lose his time. The coroner rightly enough urged that it was a citizen's duty to attend, for, as he said, it might be a serious case, involving the liberty of someone else. Undoubtedly, the difficulty of obtaining reliable evidence as to anything which takes place in the streets is a matter of growing importance, but the cause of it is not altogether the fear of loss of time. It is the treatment to which witnesses are so often subjected by coroners and police magistrates which makes respectable men hold aloof. Some police courts are notorious for the manner in which both witness and counsel are treated. In the very issue of the *Daily Telegraph* in which Mr. Troutbeck's humility on the duties of citizens is reported, there is a report also of a case at the Marlborough Street Police Court, from which we extract the following passage of arms: "Mr. Humphreys (the solicitor) was about to put Holloway in the box, but Mr. Newton (the magistrate) said: Before you put him in the box I tell you I shall not believe a word he swears. Mr. Humphreys: I tender him as a witness. I take it that you have made up your mind not to believe him. Mr. Newton: I think that an impertinent observation. Please sit down. Mr. Humphreys further pointed out that owing to the action of the magistrate his witnesses were at a great disadvantage as compared with the police." It will be remembered that it was at the same court and before the same magistrate that only last week Sir George Lewis felt called upon to retire from his case because of the way in which he was treated when appearing for Professor Lister, who had been charged by the police. It must be obvious to everyone what an enormous responsibility is thrown upon the police by the absence of respectable confirmatory evidence, and how easy it might be for an innocent man to be convicted. It is to be feared that there is among

respectable folk a growing dislike to giving evidence and exposing themselves to all that may befall them in the witness box. In cases of accident or sudden illness in the street not only good citizenship but humanity demands that all should help. The knowing Londoner, however, has learnt the lessons of experience as taught in the morning papers, and he takes good care not to risk the witness box; and so, by the unwisdom of magistrates and coroners, it has come to pass that in the affairs of the streets only official evidence is available. This may turn out to be the germ of many evils.

THE ANIMAL OF CULTURE.

PROFESSOR ALBERT, of the Vienna University, has recently published a pamphlet on the subject of the admission of women to the medical profession. He considers that the "zoön politicon," the methodical being, the animal of culture, is exclusively the male, and that it would be waste of time for women to attempt to fit themselves for medical practice. He thinks, however, that they might be trained into useful assistants by spending "two terms in the theoretical and practical study of surgery, gynecology, and midwifery." Any such proposal, however, would be likely to be criticised as severely in Austria as it would be in England. To create a class of very inadequately trained practitioners who could not be easily distinguished by the lay public from those who have been properly trained would be a *volteface* of the most undesirable kind. Professor Albert's theoretical views of what women cannot do are not confirmed by the study of what they are doing at this moment in Great Britain and in many parts of the world. Whether they have any claim to be considered "methodical beings or animals of culture" may be open to discussion, but that they can organise a hospital and carry on surgical work on a large scale and with excellent results has been proved by experience. Professor Albert's scheme would exclude women from all professional dignity and from any but the most meagre remuneration. The women and the public of Austria are not likely to give it serious consideration. The indications in Professor Albert's paper of his superb masculine self-approval seem in this country to be somewhat out of date.

THE BLACKFRIARS SALVATION ARMY SHELTER.

THE hearing of the application made by the vestry of St. George the Martyr, Southwark, for an order prohibiting overcrowding at the above-named shelter was resumed before Mr. Slade at the Southwark Police Court on October 10th. Professor Wanklyn was called for the defence, and he stated that he had examined samples of air taken at this shelter. The results of his analysis were 8.6 parts of carbonic acid in 10,000 parts in one instance and 10.9 parts of carbonic acid in 10,000 parts in another instance. Dr. Severn, who was called for the prosecution, had found 75 parts of carbonic acid in 10,000 parts. This looks like a mistake; the highest proportion of carbonic acid hitherto found in the air of a public building being 40 parts in 10,000. Professor Wanklyn expressed his willingness to have a fresh analysis made by himself, Dr. Severn, and a third person. The case was again adjourned.

THE SICK POOR IN IRISH WORKHOUSES: MEDIÆVAL CASTLEBLAYNEY.

OUR Special Commissioner's account of Castleblayney Workhouse reveals a state of things almost mediæval in the indifference to all that we have learnt to consider sanitary and becoming. There are no indoor closets, no water is laid on, the roller towel is used by all the patients in common, the female lunatics have no paid attendant, what wonder that they showed evidence of neglect in dirt and unkempt hair and slovenly attire. The wards are insufficiently lighted and ventilated, and, as is always the case, the aged and

infirm have no attention at all at night after they are locked in. This being the invariable custom the guardians are content to accept it, but will they try to realise what it means? Old people are wakeful, and the weary vigil of age and helplessness is aggravated by the oppression of foul air and the impossibility of obtaining any help if such were needed. We note that the medical officer has prevailed on the Board to do something towards bringing the sanitation of the house up to modern standards of healthfulness and decency. Much more will remain to be done before it can become a model institution, but we may congratulate the medical officer on this important advance. The union doctor is often the only voice crying in the wilderness of ignorance and prejudice. The lot of the neglected pauper may soon be alleviated by a general awakening of the public conscience; but when that day comes let all honour be given to those who were first in the field, who, unsupported by public opinion, unaided by praise, have so long championed an unpopular cause—the cause of the helpless poor—against the ignorance and prejudice of the average guardian and the hidebound officialism of an obsolete system.

THE "CHURCH ANTIVIVISECTION LEAGUE" AT NORWICH.

A BRANCH meeting of this Society was held last week at Norwich, and four addresses were given in the usual style by three clergymen and a lady. Dr. Beverley and Dr. Burton-Fanning then addressed the meeting and explained the real facts. A vote of thanks was given to them, and a good account of their addresses was published in the *Eastern Daily Press*. It is difficult and thankless work for any member of our profession to speak at such a meeting, and expose himself to be talked about for a week after it. But, as a rule, if he has carefully selected and arranged his arguments beforehand, he obtains a good hearing, and may even carry an amendment to the effect that, under the restrictions of the Act, experiments on animals ought to be allowed. The proofs which Dr. Beverley and Dr. Burton-Fanning selected were taken from abdominal surgery, cerebral localisation, and the antitoxin treatment of diphtheria. These examples, and the use of thyroid extract in myxœdema, are exactly suited for meetings of this kind; and it is worse than useless to speak on these occasions unless one is well provided with the right sort of facts, arranged ready for use. The Secretary of the Association for the Advancement of Medicine by Research (57, Wimpole Street, W.) is always glad to send literature regarding experiments on animals to anybody who wishes either to speak at a meeting or to study the subject for himself.

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS.

THE annual meeting of Fellows and Members of the Royal College of Surgeons of England will be held on Thursday, November 7th, at 8 p.m. The report to be then presented sets out in full the new by-laws (Sections iv, xvi, and xxv) which have been approved by the Home Secretary, and signed by him, by the Lord Chancellor, and by the Lord Chief Justice. The last election of members of Council was held under the revised by-law dealing with this matter. The most important new by-law is that determining the powers of the Council in dealing with cases of misconduct of Fellows or Members. The Council will in future be able to deal with many cases of misconduct of which under the more limited scope of the old by-law they were unable to take cognisance, and the disability under which the Council formerly not infrequently laboured of being unable to take action against Members of the College whose names had been removed from the *Medical Register*. The question of the admission of women to the examinations for the diploma of Member will come up for consideration, but before any final decision is taken it will probably be found advisable

to await an opportunity for consultation with the Royal College of Physicians, since at the present time the diploma of Member is practically only granted in conjunction with the licence of the College of Physicians. The tone of the report in the paragraphs dealing with finance is somewhat desponding and puzzled. The receipts are less and the expenditure greater. The decrease is due in part to a falling off in fees for the Fellowship Examinations, in part to other causes, but in the main to a decrease in the payments received from candidates at the First and Second Examinations for the Membership. The decrease on the Second Examination was anticipated, since there had been a decrease on the First Examination in the previous year; but the Finance Committee express the opinion that "the continued falling off in the receipts on the First Examination calls for the most serious consideration." No explanation is suggested, but it may be assumed that its causes are similar in nature to those which have in recent years caused an appreciable decline in the number of new students entering at the medical schools. Among these are to be numbered the greater activity of the northern schools of medicine, many of whose students seek degrees from the Victoria and the Durham Universities, and the growth of the Cambridge School, in short the growing disposition to seek elsewhere than in London a degree in medicine, the value of which is becoming more and more appreciated by medical students and their parents and guardians.

HOSPITAL ACCOMMODATION IN LONDON.

At a meeting of the Marylebone vestry held on October 10th, Mr. E. White, J.P., presiding. Mr. A. Wynter Blyth, medical officer of health of the parish, reported that six cases of scarlet fever in the parish were notified to him that morning, and an urgent case of diphtheria, for which there was no available accommodation in the hospitals of the Metropolitan Asylums Board. He had succeeded in getting the urgent case of diphtheria admitted into the Middlesex Hospital, but the cases of scarlet fever remained unisolated in private houses, mostly in one- or two-roomed tenements. In the course of a heated discussion, Sir Edwin Galsworthy, chairman of the Asylums Board, said the Marylebone vestry was not relieved of its responsibility because it was the especial duty of the Asylums Board to take infectious cases. The Board had been, and now was, doing its level best to meet all emergencies, and to keep pace with the demands made upon its accommodation. It was decided to convene a conference of delegates of London local authorities to "consider the position of the Metropolitan Asylums Board as the body which provides for the cure of infectious diseases in the metropolis."

THE BALY MEDAL.

Arran the delivery of the Harveian Oration before the Royal College of Physicians, by Dr. Church, this day (Friday), the Baly Medal will be presented to Dr. W. H. Gaskell, F.R.S., of Cambridge. The Baly Medal was founded in 1886 by Dr. F. D. Dyster "in memoriam Gualielm Baly, M.D.," and is awarded every alternate year to some person who has distinguished himself in the science of physiology, especially during the two years immediately preceding. Dr. William Baly, whose memory is thus commemorated, was at the time of his death, in 1861, by a rather singular accident on the South-Western Railway, Assistant Physician to St. Bartholomew's Hospital, and was joint Lecturer on Medicine with Dr. (afterwards Sir George) Burrows. He was also Physician to Millbank Prison, and in his Goulstonian Lectures on Dysentery had described the second epidemic of that disease (1846-7) in that prison. He was Physician to the Queen, and in large practice at the time of his death, at the age of 47, but his earlier years were devoted to the study of physiology. He was the translator into English of Müller's *Physiology*, and it was for this reason that when his friend Dr. Dyster, of Tenby, desired to perpetuate Dr. Baly's

memory by a medal, he associated it with physiology. The first award was made in 1869, and the recipient was Richard Owen; among the names of those who have since received it are those of Claude Bernard, Carl Ludwig, Charles Darwin, and Brown-Séquard, to mention only those who are no longer with us.

DISCOMFORTS OF RAILWAY TRAVELLING.

A TIME is within the memory of many of us still living, when we were grateful if we arrived at the end of a railway journey without having received bodily injury, and when a diet of station sandwiches (celebrated by Dickens in *Mugby Junction*) was considered sufficient for our bodily wants upon a journey. At the present time much has been done to ameliorate the condition of the railway traveller, but there is one important reform which requires to be completed on all trains before it becomes of any use to the public. We refer to the provision of lavatory accommodation for all classes. By the present arrangement the traveller may get a lavatory carriage of any class, but until he starts on his journey he seldom knows whether he will do so or not. For first-class fare we pay about 3d. a mile, or double the fare generally paid in North America, where lavatory accommodation is universal. As a preliminary step to getting this supplied to all classes, the public should insist on having it provided on all first-class carriages, and decline to use them at all until such accommodation is provided. The public would be more satisfied to find comfort in this particular in their journeys than even the saving of a few minutes of time on the journey to Scotland—a matter of very little importance to most of us.

FEES TO MEDICAL WITNESSES.

A CORRESPONDENT, signing himself "H. E. C. C.," sends a graphic account of his experience as a witness before magistrates. He is acting as assistant medical officer of an asylum in the Midlands, at which an attendant recently attempted to commit suicide. The case had, of course, to be investigated in Court, and the medical superintendent requested "H. E. C. C." to attend, "in case his evidence should be wanted." He attended accordingly, without any summons (mistake number one). On being called into the witness-box he asked for his fee, and was promptly rebuked by the presiding magistrate—a Major, pompous, overbearing, and apparently ignorant of law, who bullied his brother magistrates and everyone else present in the Court. The Major threatened to commit the young medico for contempt of court, and here "H. E. C. C." gave in, and gave evidence without any fee (mistake number two). The Major and his brother magistrates happened to be members of the asylum's committee, and "H. E. C. C." has since been informed by one of the others, that evidence such as his is never rewarded with a fee in the courts of the magistrates in that county. The statement of their practice is probably accurate, but the practice is palpably wrong. A medical witness is entitled to his fee as a professional man, whether his evidence is technical or scientific, or not; and he renders himself liable to no penalty if he refuses to give evidence till his fee is paid. The safer course is to keep out of court altogether until a summons with the proper fee has been served. A witness who attends voluntarily, as "H. E. C. C." did, puts himself at the mercy of the Court; and if he should be rudely treated by an overbearing chairman, must take the consequences of his own indiscretion in so attending. Possibly "H. E. C. C.," if he had persisted in his refusal to give evidence without his fee, might have been wrongfully committed for contempt of court, and so become a martyr. He might even have brought an action for damages against the Major, and obtained a substantial solatium for his wounded feelings. But these possibilities cannot now be realised. "H. E. C. C." has merely been added to the number of his professional brethren who have been refused their proper remuneration. The Major and his brother

magistrates will continue to decide cases regardless of law or justice until someone who is bold enough to insist on his rights comes before them. The right to some remuneration is clear; but rights are useless if not enforced. An opportunity of demonstrating that they exist has been missed.

FARNBOROUGH DRAINAGE.

An announcement of considerable interest with regard to this pressing matter was made at the meeting of the parish council last week. Mr. Radnor, the expert called in, looking at the question quite impartially, sees that the evils of the present system will never be completely remedied, though possibly they might be patched up. He therefore advises the council to face the position boldly, to abandon the present farms, and to secure a site for drainage at Cove. It remains now for the council to act on this sound advice. This new departure may be costly, but it must be remembered that any attempt to put in order the existing farms would also involve considerable present expenditure, whilst in a few years time it might have to be repeated. Moreover, there is a distinct advantage about the new scheme which could never quite be gained by any work of improvement at the old farms—namely, it will carry the drainage a considerable distance from the residential part of Farnborough, and it will certainly give to the town greater security than exists at present against disease. A decision is urgently needed.

A PRECOCIOUS CRIMINAL.

An inquest was held last week on the body of a male infant four months old, who had been brought in dead into Charing Cross Hospital, its death being due to suffocation caused by pieces of coarse blue paper, such as sugar is wrapped in, pushed down its throat; these were at once removed, and every effort made to restore the infant, but without avail. The mother testified that she had gone out for a few minutes, leaving in the room with the baby an older child of three years, who had often betrayed jealousy of the infant. On her return she found the infant choking, and at once brought it to the hospital. Subsequently the child accompanied her parents to the mortuary, and on seeing the body of the infant, pointed to it, and said, "I done it," and there can hardly be a doubt that this spontaneous confession of hers conveyed the truth. The jury wisely returned an open verdict; the only alternative, indeed, would have been for them to have found the mother guilty of causing the death by neglect. We are reminded of a similar instance where a three-year-old girl, jealous of the twins who recently arrived, took the opportunity, when the nurse was out of the way, to pull them both from their cradle, and proceeded to drag them downstairs, holding them by their long clothes, so that their heads were almost reduced to a pulp by the time she got to the foot of the stairs. It is needless to add that the infants did not long survive the ill-usage. Children of this age are apt to be very jealous of those who have come in to share with them the affection of their parents, and are wont to be excessively cruel sometimes, and of course until they are old enough there is no prevention possible except by watchfulness on the part of mother or nurse.

DENGUE FEVER AT HONG KONG.

Our Special Correspondent writes: An epidemic of dengue fever is prevalent in Hong Kong. It is characterised by its infective character, by a suddenly developed high temperature (105° or even 106.5° F. after a few hours' seizure), pain in the limbs, vomiting, coated tongue, and frequently mental aberration or excitement. In many districts it is impossible to get servants at any price. The period of incubation is under twenty-four hours. A coolie engaged as a chair carrier, after sleeping one night where the disease is raging, invariably develops the fever. Dengue being perhaps the most readily infectious disease known, it

can be understood how few Chinese escape, when it is remembered how they herd together. Eight coolies employed as chair carriers in a European house will sleep in a room 10 feet by 10 feet by 10 feet. A few deaths have occurred amongst Chinese. Europeans have as yet escaped fairly well, although many cases have occurred amongst children. With children a rash occasionally occurs, sometimes there is coryza, at times catarrh of the throat and trachea. Diarrhoea, orchitis, and boils are common sequelae during convalescence. As regards treatment, quinine is well nigh useless. The effects of antipyrin or phenacetin are slight and transient. The real treatment is change of house and locality. In twenty-four hours, sometimes immediately, the temperature will drop to normal and a long way below (98.4°), after a change from the infected locality, especially to a higher level. Salicylate of soda is the most useful drug during the attack, and strychnine the best during convalescence. The plasmodium malarie is not present even in cases assuming a pseudo-intermittent type.

CAMARAN: A DEPOT FOR CHOLERA.

It may seem late to refer to matters which took place so far back as in March, but as we have now been enabled to obtain from official sources the exact facts and dates regarding the asserted importation of cholera into the Hedjaz by pilgrims from Bombay, we think it well to place them on record. Cholera is said to have first declared itself at Camaran amongst the pilgrims of the steamship *Mahamoodie* in lazaretto there. Now the *Mahamoodie* left Bombay on March 6th with a clean bill of health and certificate showing no deaths from cholera during the week previous to her departure. She arrived at Camaran on March 16th. During the voyage to Camaran, 3 deaths occurred amongst the pilgrims, the causes being respectively senile debility, pneumonia, and phthisis pulmonalis. On March 23rd, or seven days after their arrival, 2 of her passengers died of diarrhoea, and on March 24th cholera was declared by the quarantine officers to have broken out, that is, seventeen days after leaving Bombay, which was then free from cholera, and seven days after arriving at Camaran. The pilgrims were quarantined at Camaran for thirty-nine days, and during that time 54 of them died—28 from cholera and 26 from ordinary diseases. The surviving pilgrims, re-embarking on April 24th, reached Jeddah three days after cholera is said to have appeared in Mecca itself, namely, April 24th or 25th. The next vessel from Bombay left that port on March 16th, with no cholera deaths on its bill of health, carrying 1,021 pilgrims. She arrived at Camaran on March 24th, and four days after disembarking its passengers cholera declared itself among them. The vessel was quarantined for forty-five days before the pilgrims were allowed to re-embark for Jeddah. The agents state that there were absolutely no suspicious deaths on board ship on the voyage from Bombay to Camaran. After the departure of the above-mentioned vessels others set out from Bombay on March 17th and 27th, and on April 10th, 16th, 20th, etc. Of these the first three are alone of any interest, because they alone could have arrived in time to introduce cholera into the Hedjaz by the time it was known to be present there. Neither the *Naseri*, leaving Bombay on March 17th, nor the *Mobile*, starting on March 27th, suffered from cholera at Camaran, and they were allowed to proceed after the usual ten days' detention always in force. The *Naseri* on the voyage to Camaran had 4 deaths—2 from old age and debility, 1 from convulsions, and 1 from central hæmorrhage—while the *Mobile* had 2 deaths—1 from tuberculous meningitis, the other from pneumonia. The pilgrims on the *Husinee*, which started on April 10th, did, however, suffer from cholera at Camaran. It is clearly evident that none of these vessels carried cholera from Bombay, but that in each case in which cholera took place the infection was incurred at Camaran—a place which, as our correspondent asserts, has been cholera tainted for the last fifteen years.

REPORTS

ON

THE NURSING AND ADMINISTRATION
OF IRISH WORKHOUSES
AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

IV. CASTLEBLAYNEY UNION, CO. MONAGHAN.

This is a large house, built originally for 1,000 inmates, though with the new regulations as to cubic space we doubt if more than half that number could be accommodated. In the infirmary the space per bed is already too small. The house is on the immediate outskirts of the town on a hill overlooking the railway. At the time of our visit the number in the house was 190, of whom 22 were in the wards and 30 altogether on the relief book. Dr. Wilson, the medical officer, kindly met us and went round the house with us. The structure plan is the same as that in the other country unions.

THE INFIRMARY

was divided among the sick, the idiots, and the maternity department. On the ground floor we went into a ward of eight beds for females, most of them being occupied; a paved passage led down the middle, but the floor under the beds was boarded. The beds were of modern pattern, elsewhere the "harrow" bed is in use. The more serious cases appeared to be in this ward. Across the passage is a stone-paved room called a day room; upstairs is a larger ward having nine beds in it. Opening out of this is a ward for children, and beyond the lying-in ward, with a staircase from it leading down to the female lunatics' quarters. On the male side the disposition is the same, except that the children's ward is appropriated to the male idiots. The nurse's rooms are in the middle block. The walls are rough surface white-washed, the uneven surface showing plenty of dust. On the ground floor the rafters are unceiled; in the floor above the roof is pitched and plastered. There was nothing to redeem the dreary aspect of the wards, the beds were crowded, only a narrow space forming a passage in the middle, and between the beds was space for a chair, but such articles of furniture are more conspicuous by their absence; a wooden bench being the most frequent seat provided for these sick folk. Straw ticks and straw pillows were on the "harrow" beds; on the iron wire wove beds we found a mattress. It is painful to see these short, narrow beds in use for the sick; the comfort of the straw tick depends on the nature of the straw and the manner in which the tick is filled, and no care can prevent the vermin which they harbour. Between the beds is a double shelf bracket, used by the patients for their mug or personal possessions. The ventilation is by the windows; those on one side are of respectable dimensions, but opposite are small slit openings near the ceiling, useless either for light or air, so that the wards are not well lighted. The fireplaces, one in each ward, have wide open chimneys, with a few bars; these must consume much fuel and give but little heat in return, and only add to the uninviting aspect of the wards.

THE SANITARY APPLIANCES

for the sick consisted of a bucket-chair in each ward, and a basin on a bracket with roller-towel suspended above, changed, as the nurse informed us, when necessary, but evidently used by the patients in common. There are no indoor conveniences, nor is there a supply of water; the hot water is heated in the kettles; there are no fixed baths, but movable baths are used in the infirmary and body of the house. All vessels used during the night remain unemptied until the morning.

THERE IS ONE TRAINED NURSE

and a paid assistant, untrained; the rest of the nurses are inmates with illegitimate children on the female side, and for the male inmates of more or less age and infirmity. There is no nurse for the night, and the sick are dependent on the attention of these mothers with their infants or the

more capable among the men. We saw several acute cases among the patients, and besides the usual belaboured cases, though the wards were comparatively empty, the time being midsummer.

THE FEVER HOSPITAL

was a pleasant contrast to the infirmary; the wards are larger and more lofty, the walls have a smooth white-washed surface, there is cross-ventilation, the windows giving a good supply of light and air. The wards are on two floors, the lower ones being a little smaller; in all the wards the fireplaces are of old construction; narrow beds and straw ticks are used in this department, and if the frames were wider we should not quarrel with these for infectious work. There is a laundry and kitchen, but we were surprised to see how little attempt is made to keep the apparatus in serviceable repair; the kitchen grate was out of order, and we saw the nurse heating water for her patients on this range, of which the front bars were falling out and the bottom bars deficient; in the laundry also most of the service pipes were split. The nurse in this block has had six months' training at the Fever Hospital, Cork Street, Dublin; she had two patients suffering from diphtheria in the wards, both convalescent.

THE LUNATICS

are placed at the ends of the infirmary building. This class comprises the insane, imbeciles, and epileptics. The cells have been removed, and the lunatics are in dormitories, but their surroundings were unspeakably dreary. The wards are dark and ill-ventilated, those on the female side crowded with women in all stages of helplessness; the men are better off, as some of them are employed about the grounds. There is no paid attendant for the females; an idiot master is on the male side. There are no baths or other conveniences for washing, so that we were not surprised to see that their persons and clothing looked dirty, their hair unkempt, and no evidence of care in their appointments. What can be expected when this irresponsible class is practically left to see after themselves? The males, as before mentioned, are placed in the upstairs ward near the sick; the medical officer, doubtless confronted by a choice of evils, has probably made the best selection; but we feel that these noisy inmates are not desirable neighbours for the sick. The whole matter of the care of the workhouse lunatics in Ireland calls loudly for attention, so it is useless to attempt to alter these minor details. These patients are locked up at night, and are provided with pails and buckets for sanitary purposes. The airing-courts are small stone-walled yards. Nowhere in this department could we see anything which suggested employment or alleviation. In this direction, however, there is a move on, as a new building is in process of erection to accommodate the male lunatics, and is being fitted with all modern appliances; this building Dr. Wilson said was to be ready for occupation this year.

THE AGED AND INFIRM

are as usual in the wings of the body of the house on the ground floor. The dormitories, dark, uninviting, and cheerless, are, with the exception of the yards, the only places where these old people can spend their days; rows of harrow beds on each side, one open grate surrounded by benches. There are a few armchairs in each ward, rough walls of doubtful colour, unceiled rafters, four windows in a long ward, one at either end, and two in the middle of the length; no appearance of occupation or amusement; the old men in listless groups round the windows; the females, a few at needlework, but many too old or feeble to employ themselves; a basin and a very dirty roller towel. This was summer; when we picture the long winter's evening and the feeble light, a dreary evening brought to an end, by the turn of the key on the outside; the open pails with their contents fouling the air, already fetid with the use of the room by day, we think that the hopeless captivity of these inoffensive paupers shows an apathy on the part of the authorities that would be criminal but that, unhappily, it wears the sanction of custom. There are no indoor conveniences attached to this department, and the outside privies are at the far end of the yards.

THE NURSERY

is divided into two sections—that for the orphans, and that

for the infants with their mothers; the former is in the small room adjacent to the females' ward, and the latter is the able-bodied women's dayroom. The first class appeared to be much better cared for. The woman in charge, herself an inmate, was doing her work well, and as she was free from the interference of ignorant mothers, the poor little things had a chance. They were clean and cheerful in appearance, and looked on good terms with their nurse. In the other nursery there were about five infants; here, on the contrary, they were dirt, squalor, untidiness, and fretfulness. The infants lie on straw ticks in wooden cradles; some were being nursed and others are bottle fed, of course, the tube bottle being in favour. We were informed that a movable bath is used in this department.

RECOMMENDATIONS.

We see from a newspaper report that since our visit the Committee appointed to confer with Dr. Wilson recommends "that register grates be placed in each ward, and that every ward in the house be fitted with Turner's ventilators; that the pail and privy system be done away with, and water-closets erected all over the house." This is indeed a step in the right direction, and we congratulate the guardians on this action. We take the liberty of supplementing this recommendation by asking that the quarters occupied by the old people be improved by giving them more comforts, better beds, armchairs, more light, and more appliances for keeping themselves clean; in the hospital that a night nurse be appointed, and a paid attendant for the female lunatics. We fear to add baths and lavatories to our list, but cherish the hope that these counsels of perfection may one day win their way with the guardians.

THE SELF-SATISFACTION OF TRURO.

THIS workhouse has received a visit from two Commissioners in Lunacy, who inspected the condition of two men and eight women, and reported "the accommodation to be fair; rooms, beds, etc., clean; and that the patients appeared to be well cared for." The Board is delighted, and contrasts this report with that given in the BRITISH MEDICAL JOURNAL of September 19th, 1894, which they are pleased to describe as "rather unsatisfactory." In turning to that report, we note that it does not deal with the condition of the lunatics, except so far as they would come under the class of patients; but if any of our readers refer to the report in question they will see that it deals with hard facts of insufficient nursing, especially at night, and antiquated wards and appliances for the treatment of the patients, a manner of dealing with the sick pauper which ought not to be a matter of congratulation on the part of the body responsible for such a state of things. Considering how much the attention of the public has been directed to this house, first during the inquiry into the conduct of the master, and then through the controversy respecting the appointment of an untrained nurse as assistant, it seems to us that the most businesslike course would be to make an earnest effort to set the house in order, and wait for congratulations when solid progress could be reported.

NURSING IN WORKHOUSE INFIRMARIES.

As a corollary to the movement which has been so effectively developed by the BRITISH MEDICAL JOURNAL in its reports on provincial workhouse infirmaries on behalf of better nursing arrangements existing in these public institutions we are glad to see that an association has been formed entitled the Workhouse Attendants Association. Among the officers are: *Patron:* Her Royal Highness Princess Christian. *President:* The Countess of Meath. *Vice-Presidents:* Adelaide Duchess of Bedford, the Duchess of Rutland, Constance Marchioness of Lothian, the Lady Bloomfield, the Lady Knightley. *Mrs. Hugh Rathbone*, *Miss Home-Cochrane*, *Sir William H. Broadbent, Bart., M.D.*, and *Rev. J. W. Horsley, M.A.* *General Committee:* Mrs. Edwin Booth, *Miss Bramston*, *Poor Law Guardian, St. George's, Hanover Square*; *Mrs. Charles*, *Poor Law Guardian, Paddington*; *Miss Clifford*, *Poor Law Guardian, Bristol*; *Miss Eyre*, *Miss Glossop*, *Mrs. Angus Hall*, *Mrs. Healey*, *Poor Law Guardian, Liverpool*; *Mrs. Heniker*, *Poor Law Guardian, Fulham*; *Mrs. Burdon-Sanderson*, *Oxford*; *Mrs. Shaen*, and *Mrs. Arnold Toynbee*, *Poor Law Guardian, Oxford*. *Honorary Secretaries:* *Miss Lee*, 20, *Bryanston Street, Portman Square*, and *Miss Mary E. Johnson*, 5, *Upper Park Place, Richmond, Surrey*.

A further executive Committee has been appointed including *Miss Louisa Twining*, *Poor Law Guardian, Tunbridge*.

This Association is formed for the purpose of introducing trained attendants into the wards for the aged and infirm, epileptics, imbeciles, and infants in workhouses. At the

present time the charge of many of these wards devolves upon wardsmen and wardswomen chosen from among the inmates. Now that public attention is especially directed to the condition of paupers it is generally acknowledged that some change in this arrangement is desirable. In England the workhouse is the only national refuge for the old and infirm poor. In France and Germany they are received in hospices and tended by "the Little Sisters of the Poor" and by deaconesses. This Association trains in well-managed institutions women to take charge of these wards, who will, while adding considerably to the bodily comfort of the inmates, raise their moral and religious tone. The Countess of Meath has paid for the training expenses of the first six suitable probationers, and it is earnestly hoped that the public will generously come forward to assist in the extension of this scheme.

WATERBORNE DIARRHŒA AND DYSENTERY.

AN outbreak of diarrhœa and dysentery in the city of Melbourne, ascribed to the agency of drinking water, and located within a circumscribed area and brief space of time in 1892, is of such importance as to demand that it be permanently placed on record in our English Indian journals. The report, which is elaborate and valuable, is by Dr. D. Astley Grosswell, the health adviser to the colony of Victoria. The circumstances briefly summarised were as follows:—

In the last ten days of November, 1892, there occurred in a well-defined and limited section of the city (hereafter termed the "block," seeing that it comprised only a block of streets) an outbreak of diarrhœal disease in circumstances which seemed to point to some factor common to the whole block, and common only to that block, since the attack occurred with great simultaneity, and all within the epidemic area thus sharply defined. Inquiry of a special and close character showed that 185 separate premises were involved in the block, and from the 144 occupied tenements information was forthcoming of a sort to help the inquiry. It was found that 140 of these took the tap water common to the city generally, and that of 53 of these habitually taking the water in a boiled state only 1 (1.8 per cent.) was invaded; that in 14 the water was generally boiled, 3 (14 per cent.) being invaded; and that of 68 in which the water was as a rule taken unboiled and unfiltered, 34 (50 per cent.) were invaded. There were indeed other 8 houses invaded, but Dr. Grosswell does not insist on these, since they may not have had relation to the particular outbreak, owing to dates of occurrence and the like; but even apart from these there was much to condemn the water as the causative agent, and accordingly further inquiry was made to determine the point outside the special area, that is, immediately outside it, and the facts elicited showed that in 93 out of 105 houses giving information outside the block in which the same tap water was taken, there had been in the epidemic period cases as follows:—At 15 houses taking boiled water, and at 7 using filtered water, no illness; at 21 generally boiling the water, 1 case; and only 1 again at 55 houses using the water in a raw state. Here, then, was an enormous difference of attack incidence on houses inside and outside the block, and, as regards the former, on those boiling and those not boiling their drinking water.

Now the disease in question was of a diarrhœal nature, as already stated, and was accompanied by severe abdominal pains, by vomiting, and by passage of blood *per rectum*. What were the circumstances whereby the water, if, indeed, water were the cause, could have acquired its property for harm in such a small section of its reticulation? The reason was not far to seek. On November 23rd the pipes of the block thus invaded had been cleared of all water for the purpose of doing some repairs to the service mains of certain premises in the block. In order to complete the repairs the water was turned off from the mains running round the streets of the block and the fire plugs in the streets were, some of them, "staked" with the view of more quickly emptying the mains. The fire plug in use was similar to what is known in this country as the ball hydrant, an arrangement which permits of the ingress of all sorts of surface impurities at certain states of pressure in the mains. It was immedi-

ately after this emptying of the mains in the block that the epidemic outburst occurred; and elaborate experiments were made in January with the pipes treated in precisely the same manner in which they were treated on November 23rd, with a view of ascertaining if possible how the disaster might have been brought about. The single exception was that after emptying, the mains were flushed out copiously, and the first water issuing from a particular hydrant collected and analysed. The water issuing in the first half minute consisted of foul liquid mud, seven to twelve buckets full, an analysis of a sample showed it to be in the main composed of foul matters, derived in chief part from an adjacent sewer, or rather open gutter, only 5 feet away and at a higher level.

It was thus seen that on November 23rd, when no flushing took place, similar filth to that issuing on the day of experiment from the hydrant must have found its way into the systems of consumers of the water in the block and to a slight extent also to consumers outside the block, though in a much more dilute form, the ramifications of the water service permitting only little of the water in the block mains to find its way outside the epidemic section. Now we learn that the fire plug openings are fixed, and that service pipes are also fixed in Melbourne (without intermediate service box) near to, below, and actually into urinals, drains, etc., and that leaking mains are permitted to lie just beneath street gutterings and immediately alongside the foulest of open pervious drains in soil thoroughly saturated with putrid filth. Thus either by way of open fire plugs or by way of leaking drains and leaking water mains—which are apparently numerous—the water of Melbourne at this time could have become fouled. These mains are open to access of human urine, animal excrement, sweepings, and all sorts of street and household filth. It was no doubt accidental that particularly foul filth was present in juxtaposition to the emptied mains in this block, but the same thing might have been happening on a smaller scale all over the city. The water at the time of the epidemic was noticed to be milky, foamy, fermented, and discoloured. And as lending additional colour to the condemnation of water as the *vera causa* of the dysenteric diarrhoea, the experiments carried out on the block mains in January, after the manner of November 23rd, and notwithstanding the subsequent flushing, were followed by diarrhoeal illness of a like kind in the inmates of some of the houses in this block.

WELL-VACCINATED LOCALITIES.

MR. ALEXANDER WHEELER (Darlington) writes to us: Will it ever be possible for your pen to do us justice? The BRITISH MEDICAL JOURNAL of September 19th says: "The towns which have suffered most from small-pox epidemics are those in what are known as the woollen districts—Bradford, Keighley, Dewsbury, Leicester, etc., where vaccination has been most neglected."

Take Bradford. It is not there that vaccination has been most neglected. A glance at the vaccination Local Government Board returns would have prevented your committing yourselves to so serious an error. Vaccination is patronised and enforced in Bradford; but take Keighley, not only is there little vaccination there, but there is little small-pox since vaccination fell out of use; and by what perversion of fact you could say it was a place that "suffered most" from small-pox epidemics I cannot understand. It is not true. Nor is it true of the other two. Leicester has not suffered anything like as much as Birmingham or Sheffield, where vaccination is run as the salvation of men. You must surely be both bigoted and sore to use such words.

Now take this town, it has let vaccinations run down, in obedience to a strong popular desire, but the small-pox is simply absent, from the wise action of the authorities in pulling down the old small-pox habitat and treating all new dwellings as places where sanitation must be followed.

It is no use trying to blink the issue of the war; the fact is out, and is well known, that there is not the least need to be in fear of small-pox if there is the proper care to keep out of the abode and lie the results and effluvia of decaying organic matter.

The following tabulation of the facts of the epidemics referred to will offer sufficient answer to Mr. Wheeler:—

Ten Years.

	1886	1887	1888	1889	1890	1891	1892	1893	1894	1895
Bradford, Yorks:										
Percentage of default under Vaccination Acts ...	5.1	4.9	4.1	7.1	6.6	16.7	14.0	20.4	21.7	21.0
Deaths from small-pox ...	2	—	—	2	—	—	2	1	—	—
Rate per 1,000 population ...	0.00	0.00	0.00	0.01	—	—	0.00	0.00	—	—
Sheffield:										
Percentage of default under Vaccination Acts ...	5.1	5.3	4.6	4.3	3.4	2.2	5.3	5.1	5.4	6.9
Deaths from small-pox ...	4	2	24	8	—	27	60	—	—	—

Leicester* (all deaths from small-pox to 1891 registered in Blaby district):										
Percentage of default under Vaccination Acts ...	20.2	43.3	47.9	52.1	60.1	72.2	77.0	79.6	84.7	88.9
Deaths from small-pox ...	—	—	—	—	—	—	—	—	—	—
Rate per 1,000 population ...	0.00	0.00	0.00	0.00	—	—	—	—	—	—

* Leicester vaccinates and revaccinates all exposed to infection whenever a small-pox case arises.

All the facts for the other towns named cannot be given. It must be held in mind that the vaccination returns issued by the Local Government Board convey no true idea of the state of vaccination of the whole population, as, for instance, we know of Leicester that two years back the medical officer of health estimated 98 per cent. to be vaccinated. It is unvaccinated and badly vaccinated sections of communities (rather than whole populations, which are variously circumstanced as to vaccination) that suffer most from small-pox.

THE EVOLUTION—PAST AND PROSPECTIVE—OF MEDICAL AND SANITARY WORK IN INDIA.

By BRIGADE-SURGEON-LIEUTENANT-COLONEL KENNETH MACLEOD, M.D., LL.D.

QUESTIONS of medical reorganisation and sanitary development in India are at the present time undergoing keen discussion. There seems to be a general consent that some change is necessary and impending; but the grounds on which that change is needful and the manner in which reform is to be accomplished do not appear to be always clearly realised. Service considerations seem too large in the argument, and it is not sufficiently held in view that medical and sanitary administration must constitute a part of general administration; and that questions of reorganisation must turn upon the condition and requirements of the country, and not upon the history or qualities or rights of present establishments, or the claims and qualifications of those who clamour to replace them. A review of the evolution of general and medical administration in the past is necessary in order to understand clearly the faults of the present and needs of the future in respect of medical and sanitary work.

For this purpose I have drawn up a table in which the more prominent features of the history and administration of India, since the granting of a charter to the East India Company in the year 1800 up to the present time, are stated on one side, and the consequent changes which have taken place in the strength and constitution of the medical services are shown on the other.

Scheme of Administrative and Medical Evolution in India.

Historical.

seventeenth century. Factory, writers, native agents and subordinates, ships, a few soldiers.

Eighteenth century. Acquisition of territory by conquest or request, war; armies, white and black; navy, civil administration, by presidencies and districts, of acquired country; collectorates, courts of justice, galleys. Police established, and subordinate revenue, judicial and clerical services organised.

First Half of Nineteenth century. Extension of territory; increase of army and navy; annexation of new provinces; centres of civil government multiplied; provincial administration created; considerable attention paid to education and medical relief; peace, protection, and commerce extending.

1807. The Indian Mutiny. Extensive disorganisation of military establishment and civil government.

Suppression of mutiny; augmentation of European army; resumption of civil administration.

1858. Honourable East India Company abolished, and government of India assumed by the Queen.

Some administrative confusion in consequence of transfer of Government from the Company to the Queen.

Reorganisation, military and civil. Rapid progress in peaceful government, and great increase of schools and hospitals; local self-help encouraged in these. Some measure of self-government established in presidency towns.

Realisation of great sickness and mortality among soldiers, prisoners, and population; deplorable sanitary condition of country becomes evident.

1872. Lord Mayo's policy of decentralisation gives increased responsibility and power to local governments. Considerable increase of activity in medical and sanitary matters follows.

Expenditure of separating military and civil medical administration fully realised. Progress in public medical relief, medical education, sanitation, vaccination, and vital statistics continues.

1882. Lord Ripon's scheme of local self-government elaborated. Municipalities and local bodies created and entrusted by law with power of collecting and spending money for local purposes—medical relief and sanitation among them.

From this bird's-eye view of Indian administration, it is evident that our government of the Empire has been pervaded by several well-defined principles, chiefly (1) Military unification; (2) separation of civil from military administration; (3) decentralisation of civil government; and (4) development of local self-government. It is on these lines that progress will proceed in the future, and any change which is considered necessary in the interests of the country ought to take the shape of gradual development rather than abrupt revolution.

The recent creation of four army corps under one chief is another step towards consolidation of the military forces of India. Probably a higher degree of assimilation of the

Medical.

Surgeons to attend officials; hospitals for soldiers and unfortunates; compounders and dressers to assist.

Increase and medical establishment for attendance on officials and troops and service in navy. Superintending surgeons and Medical Board appointed. Company's medical officers posted to districts for attendance on officials and charge of Government posts, hospitals, etc. Apothecaries and native doctors trained in hospitals.

Medical staff enlarged; all medical supervision conducted by Company's officers; civil charges multiplied; hospitals and dispensaries established for medical relief of general population, vaccination started; medical schools founded; subordinates trained in these employed in subordinate posts; some attention paid to sanitation of military cantonments and civil stations.

Medical officers largely utilised on service; serious check to medical and sanitary progress.

Gradual return to the *status quo ante*.

Great jealousy and friction between British and Indian medical services.

1850-63. Indian Medical Service closed; civil medical duties largely entrusted to trained Indians and "casuals." Increase of uncontented and subordinate medical services.

1868 Indian Medical Service reopened. Officers restricted to charge of native army and civil employment.

1866 Administration of British Army hospitals and medical staff assigned to British Medical Department.

1867. Civil Medical Department organised. Provincial governments appoint their own medical inspectors.

1868. Sanitary Commissioner with the government of India appointed.

1868. Provincial Sanitary Commissioners created. Considerable friction between medical and sanitary departments and between imperial and provincial medical inspectors.

Provincial governments take medical and sanitary matters more into their own hands, and resent interposition of military medical department.

1880. Military medical administration unified, separated from civil, and placed under one head. Civil medical administration reorganised and placed under control of provincial governments. Licentiates and graduates of Indian medical schools settling in practice in large towns and villages.

Local bodies support and found hospitals and dispensaries, and employ medical subordinates for medical and sanitary purposes. Great increase of sanitary work, and closer attention to health matters in general.

native to the European section of the army will result in the course of time; and the question of amalgamating and unifying the Army Medical Executive, medical administration having already been amalgamated and unified, will eventually arise. Meantime the differences of constitution and location of the two sections of the Army, and the different conditions under which the medical executive of each are engaged, will probably militate against consolidation of the latter.

Military and civil medical administration have been completely separated since the year 1880, and the system then commenced has worked well. No complaint has arisen from the Governments under which they have served of inefficiency or neglect on the part of that section of the Indian Medical Service which is employed under civil administrations. On the contrary, it is allowed that the work has hitherto been done well, and that officers of the Indian Medical Department have rendered splendid services in war and peace—in medical relief, sanitation, vaccination, education, the management of prisons and asylums, and in many other capacities. It is true that they are primarily recruited for military service, are trained in the Army Medical School at Netley, have to serve two years with the colours, and are liable to recall from civil employ in case of military exigency. As a matter of fact, this recall has seldom taken place since the Mutiny, and as a matter of experience these officers are none the worse—rather the better as regards status and discipline—for their military training. It was once the fashion to disparage military medical work. It consists after all in treating the sick and wounded and improving the sanitation of barracks, lines, cantonments, and camps. In India it is frequently combined with civil work. The work is by no means paltry nor the men incompetent, and the reduction of the death-rate of the European army from 60 to 12 per 1,000 is no mean achievement.

Equally anachronistic is the phrase "fossil seniors." Administrative officers in these days are the survival of the fittest, and are carefully selected both at home and abroad. That the liability to recall to military duty has not damaged the work of civil surgeons in India is quite certain. Whether the policy of maintaining in this manner a reserve of medical officers for military contingencies is expedient and sound or otherwise must depend on administrative considerations; especially on the question, how far the contingency of military exigency on a large scale can be banished from Indian thought. The recent cry for a purely civil service has arisen from an interested class which hopes to profit by the change, and not from those who rule the country and administer its military and civil affairs.

Even if it were decided to be advisable, on administrative grounds, to entertain a purely civil medical service, it would be necessary to obtain the same class of men as at present and in a similar way. The primary duty of civil medical officers is to attend on Government officials and their families, and take charge of Government institutions. Europeans, or Europeanised persons, are obviously best fitted for these purposes, and the universal rule in India that all official departments must, for efficiency and progress, be officered in chief by Europeans cannot with impunity be set aside in the case of the medical and sanitary services. Plenty of employment has arisen, and more will arise, as the country develops, for Indians educated in India without destroying arrangements which have hitherto worked so well.

The real cause of dissatisfaction with medical and sanitary services in India as now constituted is that disease and death are yearly ravaging the country; that sanitation is in a very backward state, and that these services are feeble in the face of conditions making for deterioration of health and destruction of life throughout a vast area covered by an immense population. What are a few hundred doctors and a few score sanitarians to the 280 millions of India? All this is quite true; but does the remedy lie in multiplying and debasing the medical and sanitary executive, and is it the duty of Government to carry medical relief to every door and compass the cleansing of every home?

The remedy consists rather in following out the lines of policy—decentralisation, and self-government—already initiated, and developing the spirit and practice of self-help and self-support among the people. This has been already

done largely as regards medical relief, but it is even more necessary in matters of sanitation. Medical relief requires a skilled agency, but the work of cleansing, which ought to commence with the home, can and must be wrought by the people themselves.

It is absurd to contemplate an army of sanitarians and scavengers sweeping the Indian Empire. The head of the house must be held responsible for the cleanliness of the homestead, the urban authority of the town and the district and provincial authorities for the execution of important works necessary for the health of the community at large. The duty of Government consists in showing why and how sanitary measures are to be undertaken. By means of advisers and inspectors the sanitary needs of the country and community are ascertained, and this done, the ruling power ought to insist on the proper steps being taken by the local authority to secure cleanliness and prevent practices dangerous to health. The present advising and inspecting agency requires strengthening and organising, and arrangements have to be made for the scientific study of disease causes.

But sanitary progress must depend on sanitation becoming part and parcel of the rule of the country and life of the people as in England. As development proceeds in this direction there will be abundance of employment for Indian medical men.

I have in these remarks designedly limited myself to principles, and avoided comment on particular proposals and plans of medical reorganisation.

The points which I have endeavoured to establish may be summarised in these three propositions:

1. The sanitary defects and defaults of India do not result from any ignorance or incapacity on the part of the Indian Medical Service, but depend upon the circumstances and habits of a teeming and ignorant population spread over a vast extent of unhealthy country.

2. The arrangements for medical aid to Government servants and medical charge of Government institutions and for medical administration are satisfactory; but the arrangements for supplying the sanitary requirements of India are rudimentary and ineffective.

3. Sanitary reform and progress can be accomplished only by educating, persuading, and empowering the people to adopt measures conducive to health as a detail of domestic and communal life. To that end the State requires an organised establishment, acting under the orders of imperial, provincial, and district authorities to investigate, report, and advise.

ROYAL COLLEGE OF SURGEONS.

A QUARTERLY COUNCIL was held at the College on October 10th; Mr. CHRISTOPHER HEATH occupied the chair. The minutes of the last meeting were read and confirmed. On the recommendation of the Museum Committee, it was resolved that the series of drawings of malignant and other tumours collected by the late Mr. J. W. Hulke be accepted, and that the best thanks of the Council be given to Mrs. Hulke for the presentation of the same to the College.

It was announced that Mr. Tweedy had presented to the Library a MS. by Archile de Verona, entitled, "De Dolori Juncturatum," and the thanks of the Council were accorded to him for his donation.

The draft report, prepared by the subcommittee, to be presented to the Fellows and Members at the meeting on November 7th next was approved and adopted.

Messrs. Heath and Howse were re-elected members of the Committee of Management and of the Laboratories Committee respectively.

The report of the Laboratories Committee gives the following interesting particulars: As regards the examination of suspected diphtheritic material for the Metropolitan Asylums Board, no fewer than 4,431 specimens have been examined and reported upon during the four months June to October. The average number of specimens examined per day has been 15. Since September 1st the Director has supplied about 750 doses of antitoxic serum for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, and he hopes to be able to meet the demands of the hospitals, which are, however, somewhat greater than was

anticipated. The Laboratories Committee, on the recommendation of the Director, have given £100 from the grant made by the Goldsmiths' Company for researches on the antitoxin treatment of diphtheria, to Dr. Cartwright Wood, who is carrying on investigations as to improved means of treating the horses with a view to obtaining the serum in a shorter time than is possible by the methods hitherto in use.

It was resolved that the following institutions be added to the list of recognised places of instruction in chemistry, physics, and biology—The University College of North Wales, Bangor; Wyggeston School, Leicester; Victoria Institute, Worcester (without biology)—and that the National Hospital, Queen Square, W.C., be recognised as a place of study during the fifth year of the curriculum.

The College of Physicians have decided to appoint six delegates to confer with a like number from this College upon the question of the examination for the fifth year.

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

Mr. E. C. CRISP, M.R.C.S. Eng., L.R.C.P. Lond. (Cirencester) writes: The reports of deaths under chloroform which appear in almost every number of the BRITISH MEDICAL JOURNAL form very melancholy reading. In the case reported by Mr. Coates on October 12th, it would be interesting to know why chloroform was administered in preference to ether. The heart's action was ascertained to be feeble before the operation, and there seems to have been nothing to contraindicate ether, so that the case was essentially one in which ether and not chloroform should have been used, and in all probability if it had been the patient would have been alive now. Ether may be contraindicated in a very few instances, but in the large majority of cases it is the best and safest anæsthetic, and it seems almost criminal to use in preference to it chloroform, which is five times more dangerous.

Dr. E. W. Dickson has favoured us with the following notes of a case of death under chloroform which occurred at the Coombe Lying-in Hospital, Dublin, on September 23rd: The patient, A.S., aged 38, was prepared for chloroform on September 23rd, in order to have the uterus curetted for an incomplete abortion. There was no evidence of cardiac disease. The heart was examined by Dr. F. W. Kidd, Master of the hospital, who also took charge of the pulse. Chloroform (Duncan and Flockhart's) was administered drop by drop on the ordinary face mask covered with lint. At first the patient took it quietly, and breathed well. In a few minutes she had a sort of clonic spasm of the arms and legs, then conjugate deviation of the eyes occurred upwards and to the left, and the pulse stopped. The administration of the anæsthetic was suspended when the spasm did not pass off, and artificial respiration was at once commenced. This was continued for over forty minutes, and a few respiratory efforts were made by the patient in the early part of the time, but they gradually ceased. The heart never recommenced beating. Inhalation of nitrite of amyl, hypodermic injection of ether, stretching the sphincter ani, inversion and hot stupes over the heart, were all tried, but without avail. At the necropsy the heart was found free from valvular lesion, but in a condition of fatty degeneration. About 5j of chloroform had been given, and the patient had not been fully anæsthetised. The corneal reflex was present just before the fatal issue.

SCHOOL PRECAUTIONS.

THE New York Board of Health has approved of certain recommendations which Dr. Higgs, the bacteriologist to the Board, has suggested that it should make to the Board of Education. Among these are the following:

1. The use of slates, slate pencils, and sponges shall be discontinued in all the public schools. 2. According to requirement pupils shall be supplied with pencils and penholders, each pupil to retain these received in a box provided for the purpose, such box to be marked with the pupil's name. Pencils and penholders shall not be transferred from one pupil to another without suitable disinfection. 3. All school property left in the school building by a child sick with any contagious disease, and all such property found in

an apartment occupied by a family in which a case of small-pox, typhus fever, diphtheria, scarlet fever, or measles has occurred, shall be taken by the health department for disinfection or destruction. 4. Books which are taken home by pupils shall be covered regularly once each month with brown manilla paper. 5. Places for drinking water on the ground floors of the school buildings shall be discontinued, and a covered pitcher provided for each class room, in which fresh water shall be placed before every session. A numbered cup, to be kept in the class room, shall be issued to each pupil. No interchange of cups shall be allowed.

OPENING OF THE MEDICAL SCHOOLS:

UNIVERSITY OF EDINBURGH.

The various classes in the University of Edinburgh and Extra Academical Schools were opened on October 15th.

In opening the class of the Practice of Physic, Professor Sir Thomas Grainger Stewart, after indicating the plan of the course to be pursued, went on to discuss some of the more important recent advances in medicine. Referring to serum therapeutics and immunity, two diseases had been specially studied along these lines, namely tetanus and diphtheria. The former disease was so grave, that so far as could be ascertained the mortality from it had generally been about 75 per cent.; under the new treatment, however, the most marvellous results were attained in chronic cases, and even in acute cases, when the dose of the poison was not excessive, and when the cases were seen early enough, the results were most encouraging. Passing to the subject of diphtheria, he exhibited a series of tables of cases under the care of the Metropolitan Asylums Board, von Ranke (Munich), Baginsky (Berlin), Roux, cases in the Hospital Trousseau, from Richet, Hermann Briggs, and Fanck (Brussels), to show the mortality under the old treatment as contrasted with the new; and urged that these tables abundantly proved that there was ground for great expectations from the latter. After speaking on the good effects of the remedy, he said the treatment had certain disadvantages, such as rashes, abscesses, joint inflammation. Some said that albuminuria and nephritis occurred in certain cases, but of this he was doubtful. Some maintained that paralysis was more frequent, but, if so, this was probably explained by the fact that a much larger number of severe cases recovered. The large bulk of the remedy to be injected was a disadvantage, but he believed that this would soon be surmounted. Then there was the extraordinary difficulty of the production of the antitoxin in quantity sufficient to meet the demand for it. When we were able to get more and better antitoxin he believed that better and more uniform results would be got. Finally, how were we to measure the dose to be exhibited in any given case? We required more light and more precision on this point. By and by we should hope to get remedies for the whole series of microbe diseases along these lines, and thus widen the range of our possibilities in treating such diseases. Already in this University Professor T. R. Fraser had done excellent work with regard to snake poison. In conclusion he referred to the epoch-making work of Pasteur in this relation.

Professor A. R. Simpson sketched the history of the chair of midwifery in Edinburgh University from its creation in 1726. The Edinburgh chair was, he said, the oldest professorship in this subject in any university. He gave brief notes concerning the various occupants of the chair. The latter part of the lecture was given to a eulogy of Dr. Thomas Keith, whose pioneer work led to the ultimate and amazing triumphs in the department of ovariotomy.

Professor Chiene (surgery) took as his subject the careers of Pasteur and Dr. Thomas Keith, and urged that the lives of these two eminent men were incentives to work and duty. He referred to Professor Fraser's work on snake poison, and expressed the hope that a chair of bacteriology would soon be established in the University of Edinburgh.

Professor Rutherford, in opening the class of physiology, discussed the conditions that tend to the attainment of the physiological ideal.

Sir Thomas Grainger Stewart, in opening the class of clinical medicine, took as his subject the Schott methods of the

treatment of chronic diseases of the heart. He described a recent visit to Nauheim and some cases he had seen there, the mode of treatment, and the effects of that treatment as observed by himself, and he exhibited various illustrative charts and diagrams, and explained how he proposed to carry out special inquiry in regard to the value of this treatment during the present winter session.

EDINBURGH SCHOOL OF MEDICINE.

Emeritus Professor Struthers gave the opening address at the Edinburgh School of Medicine in Surgeons' Hall, his subject being medical education. He maintained that the medical schools, much as they had advanced, had not done so as fast as they might have done. More practical teaching and more inquiry ought to be encouraged, and there should be less lecturing in these days of good textbooks. What lecturing there was should rather be in the way of comment on practical work. His remarks were not aimed at the Edinburgh schools in particular, because he believed that, taken as a whole, no schools of medicine in the United Kingdom could be compared with those of Edinburgh.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTH (MEDICAL FACULTY).

The College opened on October 9th with an introductory lecture by Professor Galloway, which was delivered in the lecture theatre of the chemical department. The lecturer was supported by the principal and staff, and several members of the Council and of the University Court.

The attendance of students overtaxed the capacity of the lecture room, and the number of entries for the entrance scholarships has been greater than in any other previous year. The medical classes commenced on the following day, and the number attending the lectures showed a steady increase. Several ladies have availed themselves of the courses of medical study open to them at Cardiff, and the admirable Woman's Hall of Residence.

The efforts made to prepare students for the higher examinations in medicine have already been appreciated by them, and in the classes of anatomy and physiology there are fourteen students preparing for the London Intermediate M.B., three for their Primary Fellowship, as well as three who are preparing for the M.B. of the University of Edinburgh. The rest of the students are preparing for the London Conjoint Board.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held in the Council Room of the Association, at No. 429, Strand (corner of Agar Street), London, on Wednesday the 23rd day of October next, at 2 o'clock in the afternoon.

The following Committees will also meet:

Tuesday, October 22nd, 1895.—3.0 P.M. Premises and Library Committee.—4.0 P.M. General Practitioners Committee.
Wednesday, October 23rd, 1895.—11.0 A.M. Journal and Finance Committee.—4.30 P.M. Parliamentary Bills Committee.

FRANCIS FOWKE, *General Secretary.*

October, 1895.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary.*

BRANCH MEETINGS TO BE HELD:

Next meeting of the District will be held at the home of the person in charge, 1000 Thompson Road, N.W., on Tuesday, October 21st at 8 p.m. Mr. W. C. Parsley will preside. Dr. W. J. Cleveland will read a paper on the subject of "Cancer." Conducting the study, and in addition to read, "The Cancer Committee," will meet at 441 E. - 12th Street, Hattaway Secretary.

SOUTH EASTERN BRANCH, WEST LONDON DISTRICT.—The next meeting will be held at the County Hall, London, on Thursday, October 11th, at 4 p.m. Dr. J. P. A. Goss, will be in the chair. Dinner at the West End Hotel at 6 p.m. after the meeting. All members of the South Eastern Branch are invited to attend, and to introduce new and old friends. Agenda: *Antropometry* for next meeting. Papers: Dr. Stanley Boyd (London): Some Surgical Cases of General Interest. Dr. Montague Murray (London): Hydrochloric Acid in the Diagnosis and Treatment of Chronic Gastric Disorders. Members desirous of exhibiting or reading notes of cases are invited to communicate at once with the Honorary Secretary, ALEX. HOWE WALKER, The Common, Cranleigh.

Borden Counties Branch.—The autumn meeting will be held at the Grosvenor Hotel, Birmingham, Kendal, on Friday, October 25th. A meeting of the Council will be held at 2 P.M. The general meeting will be held at 2.30 P.M., when the President, Dr. Smith, Dunsmuir, will take the chair. Dr. A. J. Whelan (Kendal): (1) A boy with Enormous Spleen recovering under Splenic Extract. (2) Boy case of muscular atrophy Epilepsy of Enormous Doses of Bromide. Dr. W. E. Parker (Kendal): A Cretin recovering under Thyroid Extract; and Photographs and Illustrations of numerous Urticaria before and after treatment. Dr. W. H. Cockill (Kendal): A case of Albuminuria with Atrophy of Optic Nerve closely simulating Cerebral Tumour. Dr. B. Walker (Kirkby Stephen) and Dr. A. J. McCallum: Sections of Mammary Tumours under half-a-dozen microscopes. Dr. P. F. Sturridge (Kendal): Notes on the Epitaph of 300 School Children. Dr. A. J. Newman (Bowness): Genetic Studies—a digest of the work of Dr. G. H. Scargave (Mullingham). The Hypodermic Use of Cocaine in Neuralgias. Dr. R. A. Taylor (Kendal): Bone-setters' Mispractice. Dinner will be served at 4.30 P.M., when visitors will be the guests of the Kendal practitioners in the profession with Dr. Newman, of Bowness. Visitors who have not already done so will kindly communicate their intention of being present to Dr. Parker, Kendal, not later than the morning of the 24th, so that adequate arrangements may be made.—R. D. HELLS, Honorary Secretary, Carlisle.

PETHAMPTON BRANCH.—The winter meeting of the Branch will be held in Perth on Friday, November 1st, 1885.—A. R. URQUHART, Honorary Secretary.

SOUTH OF IRELAND BRANCH—The annual general meeting of this Branch will be held on Saturday, October 24th, in the School of Art, Nelson Place, Cork, at 5 P.M. Agenda: Council's Report. Election of Officers. The following matters will be discussed: 1. The Abuses of Poles in Cork; 2. Hospital Abuse; 3. Midwives Registration Bill; and any other matters which members may wish to bring forward. Medical Society's dinner at Imperial Hotel, Cork. Members who have not previously sent their subscriptions will please do so to Dr. PHILIP J. LEE, Father's Hill, Cork.

STIRLING, KINROSS, AND CLACKMANNAN BRANCH.—The autumn meeting of this Branch will be held in the Station Hotel, Stirling, on Tuesday, October 22nd, at 3 p.m. The election of office-bearers for the year will take place and other business postponed at summer meeting will be transacted. The President (Dr. J. C. McVail) will deliver his Presidential address, entitled *Gleanings from Practice*. Further particulars by circular to members.—C. J. Lewis, Honorary Secretary, Stirling.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, at 3.15 P.M. on Friday, October 26th.—W. LEWIS MORGAN, Honorary Secretary, 27, Broad Street, Oxford.

SECRETARY JOHN L. GALT II.—The twenty-second annual general meeting of the Aviation North Western Club, opened on Tuesday, October 24, at 4 p. m., when an address will be delivered by the President, John L. Galt. Members and friends will dine together at 6 p. m. at the Grand Central Hotel, Oakland.

SOUTHERN BRANCH: NORTH-EAST HANTS DISTRICT.—The next half-yearly meeting will be held on Friday, November 1st, at 4 P.M., at the Medical Library, 1, Broad St. East, Southampton. Those desirous of reading papers or of exhibiting cases or specimens are requested to communicate with O. C. CLARKE, M.D., Honorary Secretary, 27, Elm Grove, Southampton.

BRANCH BRANCH.—The autumnal meeting of this branch will be at the Railway Hotel, Tamworth, on Friday, 25th Nov. at 8 P.M. The subject is selected by ballot, and will be given after lunch by Club Practice, and the day will be given to Mr. [illegible] and Mr. [illegible]. The [illegible] will be glad to receive notice of the meeting.—W. M. KENT.

NORTH OF INLAND BRANCH.—The members of this Branch will be held at the Royal Hotel, North Inland, on Monday, May 19, at 12 noon. Gentlemen who wish to read papers, or patients, or bring any other business before the meeting, will please call on the Secretary, Mr. J. H. B. Smith, M.D., F.R.S.E., at 10, St. George's Street, Dublin, by Tuesday, May 18, latest.

SYDNEY AND NEW SOUTH WALES BRANCH.

The thirteenth annual meeting of this Branch was held at Sydney on March 20th; Dr. W. H. CRAIG (President) in the chair. Ninety-four members and three visitors were present.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

Death of Sir Robert Duff.—The President stated that since the last meeting of the Branch the death of his Excellency Sir Robert Duff had occurred.—Dr. SYDNEY JONES proposed, and Dr. GRAHAM seconded, that a letter of condolence be forwarded to Lady Duff.

New Members.—The PRESIDENT announced the election of the following members: Mr. G. L. Murray, Sydney; J. Flynn, Sydney; F. W. Laidlaw, Melbourne; E. A. Binney, Sydney; T. P. Anderson, Kilmara; F. Deacon, Hillston; J. Kerr, Wollongong; D. Luker, Liverpool; Hugh Kirkland, Bathurst; A. Pentland, West Maitland; R. W. Crooke, Young; T. J. Henry, Warialda; C. E. Corrie, Sydney; Max Sally, Riverstone; S. Fielder, Goulford; L. J. Lammack, Waverley; K. O. Newland, Cootamundra; A. G. Crook, Newcastle; J. B. Mallory, Annandale; G. Watt, Hay; T. Lane, Inverell; J. Foran, Rylstone; A. Carvalho, Broken Hill; T. Herald, Dennington; H. Walter, Pymble; W. D. Power, West Maitland; A. G. Cooley, North Sydney; G. A. Sweet, Napier, N.Z.; R. H. Hughes, Chatswood; L. B. Key, Nyngan; E. G. E. Allen, Burwood; T. E. O. Henry, Sydney; J. C. Cox, Sydney.

President's Address.—The President (Dr. W. H. Croghan) gave his address. Dr. Frasier proposed and Dr. Knapp seconded a vote of thanks to Dr. Croghan for his address. Carried.

Officers and Council.—The **PRESIDENT** announced that the following had been elected office bearers and Councillors for the ensuing year:—**President:** Dr. E. J. Jenkins. **Vice-President:** Dr. Sydney Jones. **Councillors:** Drs. Fiaschi, Huxtable, Clubbe, W. Chisholm, Knagge, Crago, Worrall, Scot Sarving, Thring, Faithful, Coutie, Quail.—Dr. Crago then vacated the chair, and Dr. E. J. Jenkins thanked the members for having elected him President.

A GENERAL MEETING of this Branch was held on April 26th, at the Royal Society's Room, Sydney, Dr. JENKINS (President) in the chair. Fifty-four members were present.

Correspondence.—Letters were read from Mrs. White, of Singleton, acknowledging letter of sympathy; and from Lady Duff, acknowledging letter of condolence.

New Members.—The following were admitted members: Dr. Mead, Quirindl; Dr. Cunningham, Cedar; Dr. G. H. Phillips, Parramatta; Dr. L. G. Davidson, Balmain; Dr. McCredie, Globe Point; Dr. Heils, M.P., Goulburn.

Notice of Motion.—**FR. ASQUITH** moved notice of the following resolution:

That no member of Council hold office for more than three years.

Election of Auditors.—The President having explained that the election of auditors had been overlooked, moved:

That Drs. A. Jarvis Wood and G. L. Williams, who had been duly proposed and seconded, be elected auditors for the ensuing year.
Carried *unanim.*

Communications.—Dr. KENDALL exhibited a patient who had been relieved of long-standing sciatica by gymnastics.—Dr. CLINE exhibited a female child aged 3 years, suffering from a primary sore on the buttock, and well-marked rash on the trunk. Drs. ANGEL MONEY, MORGAN, MARTIN, and NICHOLS made remarks upon the case.—Dr. FOCKLER read notes on the Prescribing and Wearing of Spectacles, and gave a demonstration of modern ophthalmic optical instruments and appliances. Dr. GORDON McLEOD discussed the paper.—Dr. HENDER read a paper on a first series of Fifty Cases of Abdominal Section. Drs. THURNO and WENZEL discussed the paper, and Dr. HENDER replied.

The general meeting of the Branch was held at the Royal Society's room, Sydney, on Friday, May 31st, 1895. Dr. Jas.

KING (President) occupied the chair, and there were fifty-two members present. Drs. Lillie (formerly of Moree), Macdonald (Queensland), Haynes (West Australia) were present as visitors.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

Communications.—Dr. GORDON MACLEOD exhibited a patient suffering from Congenital Malformation of the Iris, with a Polycoria in the Right Eye, and explained the case.—Dr. W. C. MACDONALD read a paper on some Experience of North Queensland Snakes.—The PRESIDENT, Drs. SCHRODER, CHARLES MARTIN, McKAY, COLFE discussed the paper; and Dr. MACDONALD replied.

The general meeting of the Branch was held at the Royal Society's Room on June 28th, Dr. JENKINS (President) in the chair.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

New Members.—The election of the following new members was announced:—Dr. Carruthers (Balmain), Dr. Bloch (Albury), Dr. Flashman (Parramatta), Dr. Macdonald (Queensland), Dr. McBarney (Queensland).

Communications.—Dr. POCKLEY exhibited a patient suffering from Cholesteroline Crystals on the posterior surface of the Lens of the Eye, with Hemorrhage into the vitreous of the other Eye.—Dr. FIASCHI exhibited a patient suffering from Syphilis. Dr. CRAGO and Dr. ANGEL MONEY made a few remarks on Dr. Fiaschi's exhibit.—Dr. MULLINS read a paper on the Duties and Responsibilities of Medical Practitioners in New South Wales. The PRESIDENT, Dr. FIASCHI, Dr. NEWMARCH, Dr. LENNHOF, Dr. MEGGINSON, Dr. MORGAN MARTIN, Dr. SYDNEY JONES, Dr. WORRALL, Dr. POCKLEY discussed the paper; Dr. MULLINS replied.—Dr. McKAY read a paper on the Progress of Gynecology.

The usual monthly meeting of this Branch was held in Sydney, on Friday evening, July 26th, 1895, Dr. E. J. JENKINS (President) in the chair. There were thirty-seven members present.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

New Members.—The PRESIDENT stated that the following gentlemen had been elected members of the Branch:—Dr. L. J. Haynes (Perth), Dr. G. L. Lawson (Goulburn), Dr. C. O. Birch (Liverpool), Dr. G. Gillon (Darlinghurst), Dr. H. Lillie (Sydney), Dr. W. Shortt (Corowa), Dr. P. J. Kelly (Balmain).

Communications.—Dr. J. MARSHALL exhibited a case of Sporadic Cretinism. Drs. BENNETT, GILL, SCOT SKIRVING, ANGEL MONEY discussed the exhibit.—Dr. COLFE described a new Hemostyptic, *pengheer-djamhi*. Drs. FIASCHI and DIXON discussed the subject.—Dr. FIASCHI read some notes on Santini's Hydatid, resounding or booming as a diagnostic sign of multiple hydatid cysts.—Dr. VAN SOMERON read a paper on Typhoid Fever, some points in management and etiology. Drs. CHENHALL, QUAIPE, SCHRAEDER discussed the paper.

Hospital for Consumption.—Dr. SYDNEY JONES moved the following resolution:

That, in the opinion of this Branch, the establishment of a hospital for the cure of consumption in this colony is urgently required.

The resolution was discussed by Drs. KENNE, VAN SOMERON, SCOT SKIRVING, MEGGINSON, and JENKINS. The resolution was carried unanimously.

MALAYA BRANCH.

An ordinary monthly meeting of this Branch was held in the Raffles Museum on June 1st; the Vice-President (Dr. Simon) in the chair.

Cases.—Dr. HIGHER showed a case of Peripheral Neuritis following upon an attack of influenza. When he examined the patient two days after the onset of the symptoms of paresis, and ten days after seeing him for the first time suffering from influenza, he found paresis to a marked extent affecting the extensors of the feet, legs, and thighs. The patient also complained of numbness of the extremities, a feeling of pins and needles and lightning pains. The deep reflexes were absent. A week later, after large doses of

strychnine and treatment by massage freely applied, the paresis was almost gone, and the reflexes had returned although still weak. Reference was made to a similar case, in which the fingers and the heart were affected as well as the lower extremities. Dr. HIGHER also brought forward a Eurasian, aged 40 years, who presented a well-marked deep Retinal Hemorrhage in the Right Eye, and a large Separation of the Retina on the Left. The retinal hemorrhage was of only a few weeks' duration, and was apparently a complication of an attack of malarial fever. The separation of the retina was of old date, due, it seems, to an attack of plastic cystitis when a child. A history of injury is uncertain.

Confirmation of Minutes.—The minutes of the previous meeting were then read and passed.

The Diagnosis of Malarial Fevers.—Surgeon-Captain GARIO, A.M.S., read for Surgeon-Captain F. SMITH, A.M.S., of Penang, a paper on the diagnosis of malarial fevers, with some account of the malarial parasite in Malaya. The paper was illustrated by diagrams showing the various forms of parasite described by Surgeon-Captain Smith.—In the discussion which followed Dr. LEASH said that he placed less reliance upon the height of the patient's temperature than upon the condition of the pulse and respirations.—Dr. HIGHER spoke of the rarity of true types of malaria in Singapore.—Surgeon-Captain GARIO agreed with Dr. HIGHER with regard to the absence of typical malaria in Singapore. He only found classical malaria in men who had come from India. He had lately two deaths in the regiment from acute remittent fever, verified in each case by *post-mortem* examination. In both cases cerebral symptoms were very marked.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.
A MEETING of this district was held at East Grinstead on October 8th. Mr. P. E. WALLIS of East Grinstead presided.

Communications.—The PRESIDENT showed a boy, aged 10, who on June 24th, 1895, had both Tendines Achillis divided by a field mower. On the left side some inches of the tendon were torn away, some bone removed by the lower end of the tibia, and the ankle joint opened. The patient had recovered with perfect use of the ankle.—Dr. A. J. RICHARDSON showed photographs of a girl, aged 10, with a Congenital Hypertrophy of the Feet, to which the term *Scotopody* had been applied. She was in other respects well-formed and healthy. Dr. Richardson read a paper on Serumtherapy, giving a historical sketch of the treatment, and discussing the methods of immunisation and the action of antitoxins.—Mr. FORSMAN read notes of a case of Division of the Median Nerve at the Wrist-joint, in which nerve suture was practised on the fourth day after the injury. Sensation had in large measure returned a month after operation. Motor power was becoming re-established at the eighth week. After two years the hand was "as strong as ever it was," but some numbness of the index finger still remained.—Mr. A. H. DODD read notes of a case of Pulmonary Embolus occurring six weeks after delivery in an albuminuric patient recovering from phlegmasia dolens. The patient was suddenly seized with acute pain in the mid-sternal region passing through to the spine, and "felt as if bound inside with a tight cord." She presented a pale, drawn, anxious expression, dyspnoea (without cyanosis), and feeble pulse of about 20 per minute. The symptoms gradually diminished in intensity, till some five hours later the pain suddenly returned, this time in the right clavicular region, and the patient was again in *extremis*. Twelve hours later she had quite recovered.

NORTH OF ENGLAND BRANCH.

The autumnal meeting of this Branch was held at the Hydropathic Establishment, Hexham, on October 8th.

Communications.—Dr. HUMS read a paper on Appendicitis, in which he emphasised the necessity of early diagnosis and of early operation, of which he gave illustrative cases.—Dr. DRUMMOND showed examples of Diffuse Congenital Cystic Disease of the Kidneys. The patient was a woman, aged 47, the mother of sixteen children. Her health through life was feeble, but she had no illnesses of note until the last year, when recurring attacks of diarrhoea compelled her to seek the aid of her medical attendant, Dr. Johnstone Weir. The

diarrhoea persisted more or less up to the end, and she gradually lost strength and flesh. The final attack began ten days before her death, and consisted of most obstinate diarrhoea and rapid loss of strength. Forty-eight hours before death uræmic convulsions set in, with deepening coma. The diagnosis of cystic disease of the kidneys was made on recognising the uræmic condition and the presence of double kidney tumour. Dr. Drummond advanced the opinion that the disease was of the nature of adenoma, and compared the renal tumour with the common type of an ovarian cystic disease. The kidneys weighed about 2 lbs. each.—Mr. RICHARDSON MORRIS described a new operation for the cure of Vesico-vaginal Fistula. The principle on which this operation was based was a free exposure of the opening in the bladder by reflection of the vaginal wall for some distance round it and closure of the vesical opening by a continuous Lambert's suture. In the case related a horse-shoe shaped flap of the anterior vaginal wall was separated from the bladder, the opening in which was exposed and made watertight by a continuous silk Lambert suture, the ends of which were cut short. This was carefully suturing over it the vaginal flap with catgut. The operation was performed with a scalpel and ordinary needle and needle holder and occupied less than half an hour. Healing occurred by first intention.—Dr. MORRIS discussed the Pathology of Exophthalmic Goitre. He urged that the fact that the administration of Thyroid gland in Graves's disease restored health to the patient, and its discontinuance was followed by a return of the symptoms, proved that Graves's disease was due to the cessation of the secretion and decay of a permanent thyrotoxic gland. The thyrotoxic secretion had a depressing effect on the heart, circulation, and medulla, and its cessation in adults was followed by excitability of the medulla, producing the symptoms of Graves's disease.—Dr. ALLMON (Newcastle-on-Tyne) read a paper giving details of a well-marked case of Osteomalacia, and exhibited photographs showing the great improvement which had taken place under a treatment which he believed to be original, namely, by bone-marrow extract.

Dinner.—The usual dinner was held after the meeting.

NORTH WALES BRANCH.

The annual meeting of this Branch was held at Criccieth on July 11th. In the absence of Dr. EYRES LLOYD, the President, Dr. LLOYD ROBERTS was voted to the chair.

New Members.—Messrs. Wm. Cecil Fenwick, M.R.C.S., Liverpool; Richard Griffith, M.R.C.S., Aberystwyth; Llewellyn Roberts, M.D., Llandudno; and Evan Williams, M.R.C.S., Llanelli, were admitted members of the Association and Branch; and Messrs. F. H. Barrett, F.R.C.S., Liverpool, and Herbert W. S. Williams, M.R.C.S., Holywell, of the Branch.

Installation of New President.—The CHAIRMAN, in felicitous terms, vacated the chair in favour of Mr. T. HENRY HUGHES, M.R.C.S. Eng., President-elect, Chairman for South Carnarvon.

Proposed Intermediate Meeting.—Dr. LLOYD ROBERTS, J.P., Denbigh, proposed, and Mr. H. JONES ROBERTS, Pen-y-groes, seconded:

That an additional intermediate meeting in the autumn of each year be held.

On being put to the meeting, it was unanimously passed.

Election of Officers.—The following were elected office-bearers for the ensuing year: *President-elect*: Mr. Richard Williams. *Honorary Secretary*: Mr. W. Jones Morris. *Honorary Treasurer*: Dr. Samuel Griffith, J.P. *District Council*: Messrs. R. Arthur Pritchard, T. L. K. Lawley, Llewellyn, Hugh Jones, Dolgellau; H. P. Howlands, Towy; J. R. Jenkins, Ruthin; and J. Lloyd Roberts, Denbigh. *Representation on the Council of the Association and Parliamentary and Local Committees*: The Honorary Secretary was unanimously re-elected.

Minutes of Meeting.—It was resolved:

That the autumnal intermediate meeting in 1933 be held at Ruthin; the spring intermediate meeting in 1934 at Llandudno; and the annual meeting in 1935 at Carnarvon.

Report of District Council.—This report stated that the increase in numbers of the Branch was the highest in its history. Reference was also made to its flourishing financial position; to the grievous loss it had sustained in the death of Dr. A. E. Farnour, of Denbigh, the last of its original mem-

bers, his many virtues, good qualities, and intense devotion to the Branch, which had been very appropriately borne witness to in his obituary in the *British Medical Journal*; to the useful and practical papers and discussions on professional subjects brought forward at the meetings of the year; to the expression of opinion on the part of the Branch on many questions of professional polity, and the resolutions passed thereon; to the interest taken in its affairs by the members.—On the motion of Mr. LLOYD WILLIAMS, seconded by Dr. ROBERT JONES, the report was unanimously adopted.

Midwifery Registration Bill.—A general discussion, in which many members took part, on this question was concluded by the unanimous adoption of the following resolution, proposed by Mr. LAWSON TAIT, seconded by Dr. LLOYD ROBERTS (Denbigh):

That the action of the Parliamentary Bills Committee in postponing the discussion of the Bill till the Branches have had time to consider it be approved of.

Medical Defence.—The following resolution was unanimously carried:

That this matter be referred to a future meeting of the Branch, as it requires most careful consideration.

President's Address.—The PRESIDENT briefly referred to the Sanitary Conditions of South Carnarvonshire, touching upon the growing popularity of its health resorts, Criccieth and Talbally, their undoubted salubrity, and the duty of the medical practitioners of the district to keep a vigilant eye on the proceedings of the public authorities, and concluded with some excellent practical suggestions on the ethical relations of medical men.—On the motion of Mr. ARTHUR PRITCHARD, seconded by Dr. E. J. LLOYD, a hearty vote of thanks was recorded the President for his address.

Communications.—Dr. RICHARD JONES, D.P.H. Cantab., Consulting Medical Officer of Health to the County Council of Merioneth, read a paper entitled *Death and Disease among Quarrymen: a Statistical Inquiry*. A hearty vote of thanks was passed to Dr. Richard Jones for his valuable paper, and a hope was expressed that it might be circulated among those concerned in this important trade.—Mr. R. H. MILLIS ROBERTS, F.R.C.S. Edin., read notes of a case of Obturator Dislocation of the Femur, giving its history, treatment, literature, and opinions as to its causation and reduction. He was warmly thanked for his remarks.

Cases.—Mr. HENRY EVANS exhibited patients suffering from (1) Progressive Muscular Atrophy; (2) Progressive Muscular Atrophy with Epithelioma; (3) Myxoedema. Each of the cases gave rise to a discussion, in which many members joined, and Mr. Evans was thanked for bringing the cases forward.

Dinner.—In the evening the members sat down with the Rector and Chairman of Local Board of Criccieth as guests to a well-served and enjoyable dinner.

This autumnal intermediate meeting was held at Ruthin on September 11th. There were twenty-six members present. In the absence of the President (Mr. Hunter Hughes), Dr. J. R. JENKINS was voted to the chair.

New Members.—Messrs. R. T. Davies, L.R.C.P. Edin. (Prestatyn) and Evan L. Williams, M.D. (Amlwch), were elected members of the Association and Branch; and Messrs. W. H. Griffith, L.R.C.P. (Prestatyn), G. J. MacAlister, M.D., M.R.C.P. (Liverpool), and Robert Owen, L.R.C.P. (Pen-y-groes), of the Branch.

Communications.—Dr. H. DRINKWATER (Wrexham) read notes of a case of Jacksonian Epilepsy, in which he had triumphed with marked success. He detailed the steps of the operations, his reasons for the site, and the successive stages of this recovery. The paper gave rise to an interesting discussion, in which the members generally took part; and Dr. Drinkwater was thanked and congratulated.—Dr. JEROME S. DEW (Chesham, Manchester Royal Infirmary) gave a practical address on some points in the investigation of Nervous Diseases.

—Dr. J. LLOYD ROBERTS read notes of recent cases of Hernia at the Denbigh Infirmary, which was a practical summary of a series of cases differing in many particulars. In the subsequent discussion Mr. LAWSON TAIT said that he had for some time had under consideration the advisability of a median intraperitoneal operation rather than

the canal operation in cases of hernia—to pull the bowel from inside rather than push from the outside. Unfortunately his experience of hernia was not as great as for other abdominal operations, but he should wish, if the opportunity presented itself, to give his plan a trial.—Mr. W. THELWALL THOMAS, F.R.C.S., read notes of some recent cases of Bone Operative Surgery.—Mr. HUGH E. JONES, F.R.C.S., read notes and exhibited a specimen of extensive Mastoid Disease, involving a large portion of the petrous portion, in which operative treatment was refused.—Dr. F. H. BARENDT read a paper on Eczema Squamosum.

Resolutions at Annual Meeting.—Mr. LAWSON TAIT deferred action with regard to his motion regarding the resolutions at the annual meeting so that his propositions may be circulated to the members.

Luncheon.—The members lunched together prior to the meeting, and a most enjoyable meeting in one of the loveliest spots in Wales was spent.

SPECIAL CORRESPONDENCE.

PARIS.

The Medical Department in the Autumn Manœuvres.—*Insanity among Silk Spinners.*—*Suppression of an Epidemic of Anthrax.*—*Aluminium Cooking Utensils for the Army.*—*General News.*

THE hospital of evacuation organised at Bourg-la-Reine was in working order on October 10th, under the supervision of General Berruyer, director. A considerable number of medical men and members of administrative staffs went to Bourg-la-Reine. At 9 A.M. the wounded sent on from Champigny arrived; they were immediately removed from the carriages, placed on *brancards*, and carried to the wards set apart for their form of illness. On the 11th the manœuvres of the Army Sanitary Service were terminated by a lecture from the director of the manœuvres and the dismemberment of the sanitary train. This train was organised at 1 A.M. In the waggons were arranged the apparatus for suspending different kinds of *brancards*, with the necessary material for tending the wounded. At 1.30 the hospital was evacuated, and the wounded carried on *brancards* were placed in waggons. Those not seriously wounded were placed in the second class carriages, the first class carriages being reserved for the use of General Berruyer, the health service officers, the medical and civil officers. At 2 o'clock the train started for the Paris Montrouge Station, where a divisional ambulance service was in working order. The Sanitary Service manœuvres have not brought to light any novelties. The war material of the preceding years, slightly improved, again does service. As to the manœuvres for receiving the wounded, they are always equally unlike the reality and contrary to the war directions, which do not allow any of the ambulance staff to go beyond the reserves of the battalion, otherwise the bearers would be exposed to the enemy's fire. These imperfections are inevitable during the annual manœuvres, owing to want of space. It is impossible that manœuvres of this kind can give a true idea of the necessities and emergencies of actual war. The sanitary service manœuvres should be attached to the annual autumn manœuvres. One or two divisions could be set aside to simulate the wounded. The medical officers of the reserve corps could be called out, and would learn more in four days than in eight of ordinary service. It is stated that five times as many more would be working and learning for the same expense as now. After noting the above shortcomings, it is only fair to admit that the organisation of the ambulance was perfect. The help stations were quickly established and worked admirably.

M. Spratling has recently published notes of 57 cases of insanity occurring in six years among silk spinners. All the cases occurred in the same town, which has a population of less than 100,000 inhabitants. This large proportion of insane in a calling followed by comparatively few persons is a fact worthy of note. Moreover, there appears to be a connection between the position daily assumed by the workers, and their excessive mental tension, and the development of insanity. Half of the insane were predisposed by hereditary

influence. Alcoholism was a factor in only 4 cases. All the 57 cases studied by M. Spratling at the *Manège des Insensés* Asylum were very serious; 14 were cured, 5 were slightly improved, 6 remained stationary, 6 died, 26 are still in the asylum, and are considered incurable. All forms of insanity are more severe among silk spinners than among other patients. M. Spratling also observed that insanity among silk spinners becomes more and more frequent; this he attributes to the machinery, which becomes more and more complex, necessitating constant and unremitting attention on those who have to work it. Mental overstrain from this cause and positions causing severe bodily fatigue are believed by M. Spratling to be the source of insanity among the silk spinners.

At a recent meeting of the Academy of Sciences M. Pasteur announced that the letters of condolence addressed to the Academy on the occasion of Pasteur's death are so numerous that a list of them will be printed at the expense of that scientific body. It is stated that Professor Duclaux will succeed Pasteur at the Pasteur Institute. As successor he frequently replaced his illustrious chief. A letter from New Jersey, received by a prominent American member established in Paris, states that anthrax appeared among the cattle of that locality some months ago; the disease was so widespread and terrible that the inspectors were at a loss how to combat it. A petition on the subject was addressed to the Minister of Agriculture by M. Powell, President of the Sanitary Committee of Bridgeton. An order was immediately sent to veterinary surgeons to vaccinate 2,000 cattle with Pasteur's lymph. This was done, and the disease was stamped out at a cost of 2,000 francs.

When the Madagascar expedition was decided on, the French Minister of War decreed that aluminium cans and other utensils should be supplied to the regiments ordered to Madagascar. M. Balland, Principal Army Pharmacist, has presented a report to the Academy of Sciences on the advantages of these utensils. Hitherto the dearth of aluminium and its frequent deterioration have prevented it from being used for cooking utensils. In fluid kept in aluminium utensils a cloudy deposit formed, which gave them an unwholesome appearance. M. Balland in 1892 made experiments which demonstrated that aluminium in contact with vinegar in four months loses 0.349 gramme per square decimetre, and 0.045 gramme with a salt solution of 5 per cent. The Madagascar expedition has proved that aluminium utensils can be used without any injurious effects. They are durable, neither the action of fire nor that of fluids or solid food stuffs having any influence on them. The surface becomes blurred, but the weight after ten months' use is not perceptibly diminished. Food does not remain long enough in the cans to take up any considerable quantity of the metal; moreover, the compounds thus formed would be harmless.

Mdlle. Julie Goldber has bequeathed the whole of her fortune to be divided between three night asylums.

M. Lapparent and M. Bertrand are mentioned as successors to the late Professor Pasteur in the Mineralogy Section of the French Institut.

ROME.

Antituberculous Serum.—*Congress of the Medical Society.*—*News.* THIRTEEN phthisical patients are being at the present time treated in the Santo Spirito Hospital with Professor Maragliano's serum, but the investigation is not yet sufficiently advanced to permit the issue of a report on the results obtained. It is doubtful now whether any report will be issued, as the Minister of the Interior has just published a decree that for the present the antituberculous serum prepared by Professor E. Maragliano cannot be freely sold and used for treatment until the Superior Council of Health has approved of it. He deems it advisable, however, to permit the experimental treatment under the direct responsibility of the preparer, so that he may be able to test its therapeutic value. Professor Maragliano intends giving a full description of his method of preparing and using the serum at the meeting of the Italian Congress of Internal Medicine. This statement is looked forward to with much interest by the profession in Italy, as the professor has not yet published full particulars of his method.

The sixth Congress of the Italian Medical Society will be held in Rome, under the presidency of Professor Baccelli, from October 22nd to 28th. For the past two years the annual meetings have been suspended in consequence of the International Medical Congress. The King will honour the Congress with his presence. The two chief subjects for discussion are: Sero-therapeutics, introduced by Professors Foh of Turin, and Maragliano of Genoa; and the Slackening of Nutrition, introduced by Professors de Renzi and Reale. This year there will be for the first time a clinical conference on practical subjects. It will be held at the Santo Spirito Hospital, and Professors Cardarelli, De Giovanni, Gioceco, and Riva will take part in it.

The Italian Hydrological Congress was opened at Venice on October 10th, and was largely attended, especially by those members living in Venice. The Congress was opened by Dr. Vinai, the President of the Hydrological Association.

The Minister of the Interior has issued a decree prohibiting the introduction of rotten or damaged maize into the kingdom for any purpose whatsoever. It appears that large quantities of unwholesome maize have been imported from foreign countries into Italy for apparently industrial purposes and as food for animals only. The Minister states this was simply a pretext to permit its free introduction, as it was afterwards consumed as food by the poorest classes, with grave injury to their health. He also states that unwholesome maize, even if adopted for the preparation of alcohol, does not cease to be injurious to those who may drink it, and that it may also be injurious as a food for animals.

The death is announced of Dr. A. Tebaldi, Professor of Psychiatry in the University of Padua.

LIVERPOOL.

Liverpool Medical Institution.—Opening of the Session.—President's Address.

THE inaugural meeting of the session of the Liverpool Medical Institution took place on October 10th, when the usual introductory address was delivered by the President, Mr. Chauncey Puzey, his subject being the earlier history of the antiseptic movement, which, he said, might be described as terminating with the decline and fall of the carbolic spray. At first sight, he remarked, it might appear that a great part of Lister's work had been proved to be erroneous, but he believed the whole course of his work was useful and of steady progress, its successes being the abolition of pyæmia and septic infection, and the union of wounds by first intention. The results of his practice in this respect might be estimated from statistics published by Professor Simpson in his essay on "Hospitalism" in 1869, when Lister was working out his earlier methods. These statistics showed, as the results of some thousands of amputations, that the ratio of deaths to recoveries was, in Parisian hospitals, 1 to 1½, in London hospitals 1 to 2½, and in provincial hospitals from 1 in 3½ to 1 in 7, the mortality increasing with the number of beds in the hospital. In private country practice it was 1 in 9.2. In 1874 Erichsen stated that pyæmia proved fatal in 83 per cent. of primary amputations, in 44½ per cent. of secondary, and in 24½ per cent. of amputations for disease.

When he (the President) first came to the old Liverpool Royal Infirmary he was struck with the freshness of the wards and the smaller mortality after major operations as compared with his experience at Guy's, but the mortality, especially from pyæmia, was such as would be now considered terrible. Lister's contribution to the happier condition of things which now exists began in 1867, when, at the annual meeting of the British Medical Association, he delivered an address on the antiseptic principle in the practice of surgery, his plan being based on the results of Pasteur's researches. He based his practice on the principle of destroying the minute organisms suspended in the air, compound fractures being the first class of cases to which he applied it. The acid in its full strength, melted by heat, was introduced into all accessible recesses of the wound by means of a piece of rag held in dressing forceps, a piece of lint dipped in the strong acid was laid over the wound, and was covered with a piece of black tin or sheet lead. In Lister's hands this treatment was very successful, but in

other hands fatal poisoning from carbolic acid occasionally took place, and before long surgeons were content with carbolic lotion and oil. In 1871 Lister, in his address on surgery at the meeting of the Association at Plymouth, recommended the 1 in 40 solution, and for the first time fully described the well-known Listerian dressings, and he also advocated the use of the spray, employing Dr. B. W. Richardson's small hand spray producers. About this time the method was fully adopted in the Liverpool Royal Infirmary with the best results, the improvement being effected under the management of the late Dr. William Cheever, who had been Lister's house-surgeon, and who succeeded the President at the infirmary as resident medical officer.

Whatever might now be thought of the spray, he (the President) had no doubt that for many years it was a most valuable agent under the sanitary and other conditions then existing. However, from the first it met with great disapprobation, and as early as 1879 it began to be pointed out that it was not an essential part of the method, while in 1882 Lister himself began to show signs of doubt as to its necessity in the face of improved antiseptic arrangements and sanitary surroundings, and in the year 1887 he finally gave it up. There were two addresses which stood out prominently—that of the late Sir W. Savory at the annual meeting at Cork in 1879, and that by Sir W. Stokes at Worcester in 1882. Since the writing of this paper was commenced, the names of two great workers whose names gave rise to it had come very prominently before the public. Lister had been elected President of the British Association, Pasteur had been called away from the scenes of his useful work, and the whole civilised world had heard of his departure with respectful regret. Mr. Puzey concluded his remarks in the following words:

"Let us hope that Lister may be long spared to us; but, when the time arrives for his departure, I think that no better inscription could be engraved on his tomb than these eloquent words of Sir James Paget: 'More than any other he did good, both by his own work and by leading others to do their best in their own way.' For the present we can look forward with pleasurable anticipation to the time next year when we shall have him in this city as the President of the British Association. Then, I am certain, from no section of our citizens will he receive a more hearty welcome than from the members of the Liverpool Medical Institution."

A cordial vote of thanks to the President for his address was proposed by Mr. Rushton Parker, and seconded by Dr. Alexander, and carried by acclamation.

The members of the Institution were subsequently entertained at a supper and smoking concert by the President, an excellent programme being rendered by some of the guests.

The biennial dinner of the Liverpool Medical Institution took place recently at the Adelphi Hotel, the President, Mr. Chauncey Puzey, being in the chair. About one hundred members and several guests were present. Among other toasts, that of "The Clergy and the Medical Charities" was proposed by the President, who coupled the toast with the names of the Rev. J. Bell Cox, his old schoolfellow, and the Rev. John Watson, perhaps more widely known as "Ian Maclure." The Rev. J. Bell Cox, in replying, suggested that as in many of the higher grade schools, including that in which he was interested, there was a cookery class, such classes as well as other schools of cookery might be made useful in providing dinners for convalescent patients just discharged from hospitals, some arrangement being made between the hospital staffs and the school managers by which the dinners should be classified and food provided suitable to the various cases. The Rev. John Watson, in the course of his speech, took occasion to state that there were many doctors, both in Scotland and in the South, as forgetful and as utterly Christian as "William MacLure." It had been one man's good fortune to know four country doctors, each one of whom might have cut for his hero. He desired to thank his readers, and chiefly the medical profession, for the reception given to the doctor of Drumtochty. From all parts of the English-speaking world letters had come to him in commendation of "William" from doctors who had received new courage from the book.

The next Congress of French Scientific Association will hold its opening meeting in the Sorbonne, Paris, on April 7th, 1896.

MANCHESTER.

Entries.—Annual Dinner.—Extension of Royal Infirmary.

THE entry of new students at the Owens College Medical School is distinctly above that of last year, and there is a decided increase of candidates for the University degree, so that it would seem that the influence of Victoria University is making itself distinctly felt in the surrounding districts. The magnificent new laboratories of the physiological, pathological, and other departments are proving a great boon, as throughout they are equipped with all modern arrangements, so that the students have ample space for carrying on their work. It is thus possible, with the greatly increased accommodation, to allow the students to do many things for themselves which are not possible in small laboratories.

The annual dinner of the Owens College and Royal Infirmary took place last week under the genial presidency of Mr. Mold, the popular lecturer on mental diseases.

The "infirmary question" is on again. That an increase of beds is required has long been conceded, but the question is: Are the additional beds to be added to the present site, or what is to be done? A subcommittee appointed some time ago to report on this question have now sent in two reports, one on the part of the majority and the other by a minority. The following is the gist of the report. The majority stated:

That only by rebuilding would it be possible adequately to provide, in a fit and proper way, the requirements of an infirmary brought up to date essentially, with every latest improvement, and otherwise worthy of the city of Manchester. As to the plan upon which such a building should be constructed, they were unanimous that the pavilion principle was by far the most suitable, and on consulting a competent authority they found that there would be no difficulty in constructing a pavilion hospital containing the accommodation that in their opinion is absolutely indispensable, and that could be looked on as satisfactory with due regard to architectural, sanitary, and all other considerations, on the present site without covering to any important extent the land now vacant within the area of the infirmary boundaries.

While the minority:

Do not see the necessity of building an entirely new hospital, as they believe that all the necessary additions and alterations required can be provided by a modification of the existing building. The cost of a new building cannot, in the opinion of the minority, be less than, and will probably exceed, £200,000.

The following resolutions were ultimately adopted:

That the signatories to the majority report be requested to obtain full plans and elevations on which they propose the hospital shall be rebuilt on the present site, and also to obtain evidence from experts in hospital buildings and others as to the practicability and efficiency of such plans, and an approximate estimate of costs.

That a further subcommittee be appointed to obtain the opinion of experts and others as to the building of a new supplementary hospital elsewhere to provide for the additional accommodation required, to obtain plans and an approximate estimate of the cost of such hospital, and also to report as to what alterations in the present building would be necessary to bring it up to date, and to make it as efficient as possible according to modern ideas (without providing additional accommodation for patients now), with the probable cost of such alterations.

That the signatories to the minority report be asked to give full details of this scheme, and be given equal powers as to the preparation of plans and the calling in of experts as have been given to the members who signed the majority report.

CORRESPONDENCE.

LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS AND THE TITLE OF "PHYSICIAN."

SIR,—In reference to a recent article in the *BRITISH MEDICAL JOURNAL*, in which the claim of the Licentiates of the Royal College of Physicians of London to the title of "Physician" is discussed, I desire to remove all misapprehension on the subject by stating that when the class of Licentiates was established on its present basis, the College consulted the standing Counsel to the College—Sir Richard Webster, the present Attorney-General—on this very point. He gave it as his opinion that those on whom the College conferred its licence were thereby legally constituted physi-

cians. The incident is well within my recollection, and I have no doubt at all about the matter.—I am, etc.,

October 10th.

F. R. C. P.

A BRAVE DOCTOR.

SIR,—Allow me to thank you for the very laudatory remarks in the *BRITISH MEDICAL JOURNAL* of October 12th. I cannot, however, let the occasion pass without placing before my medical friends a few material details.

I was unable to descend in the ordinary way to the beach owing to the tide having cut off the path. The coast-guard officer then selected a shelving portion of the cliff, and by means of a life line fastened under his arms scrambled down, I following in the same manner, and arriving safely with a few scratches and bruises. I was at no time during the descent suspended in mid-air, as depicted in certain illustrated papers; but there is no doubt of the risky nature of the undertaking owing to the strong gale blowing and the slippery nature of the shale. Others followed in the same way; and, after all, I feel that I did no more than any man would do under such urgent circumstances. I greatly regret that we had not sufficient assistance to save the unfortunate man.

I take this opportunity of thanking the many members of my profession who have so kindly written to me on the subject.—I am, etc.,

Hiracombe, Oct. 14th.

CHAS. W. E. TOLLER.

CHITRAL RELIEF FORCE.

[Forwarded by the DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.]

SIR,—In an editorial paragraph in the *BRITISH MEDICAL JOURNAL* of September 14th in connection with the sickness from which the Chitral Relief Force appears to be suffering it is stated that "the use of Pasteur filters and the boiling of the drinking water were alike neglected, and hence the troops were severely damaged and the efficiency of the enterprise compromised." Now one would very much like to know whether this positive explanation of the sickness is founded merely on theory or on actual observation at the spot. In a letter which appeared in the *JOURNAL* on August 10th Surgeon-Major Battersby, who is with this force, said that he thought the waterborne theory would scarcely account for the prevalence of enteric fever, as the water supply in many instances had been above suspicion, being procured from springs coming directly from the mountain side. He also mentioned that European troops alone were attacked, and now we hear that among these the Bedfordshire Regiment has suffered disproportionately. By the information published one is unable to see how the neglect of using Pasteur filters and boiling the drinking water would account for the selective incidence of the sickness in general or of the enteric fever in particular, and it appears to me that this is the first fact which a theory of causation should account for.

Reports in the daily press state that there is a great amount of sickness—doubtless much of it enteric fever—among the French troops in Madagascar; yet it is reasonable to conclude that, as Pasteur filters have done so much for the army at home, they have been liberally supplied to the expeditionary force.

It would be a good thing were it possible to preserve the health of men in hot climates by Pasteur's filter or Mr. Hart's tea-kettle, but it is unfortunately the fact that ill-health and disease—in both hot and cold climates—arise from many causes. The procuring of the best drinking water possible should never be omitted, but assiduous attention to many other hygienic matters is also necessary. According to my experience, the fevers which attack Europeans in hot climates are seldom due entirely to drinking water, and frequently have little or no connection with it.—I am, etc.,

GILBERT KIRKEB, M.D.,
Staff-Surgeon, R.N.

Aberdeen, Sept. 17th.

* The statement in question was from a well-informed military source. Dr. Battersby's observations are, of course, theoretical, and based on the hypothesis of *omnis origo*. It would always in such cases be advisable to remove known sources before speculating as to unknown. It is the opposite

process which has been the cause of so much sanitary disaster. The Madagascar troops were, according to our information from Paris, equally neglected in sanitary respects, and the importance of attending to the water supply either largely overlooked or greatly neglected for the troops on march. It is unfortunate that experience gained in times of peace does not seem to be always applied to expeditions of war; in the latter case there are always much greater difficulties than in the former.

CERTIFICATED MIDWIVES AND BOARDS OF GUARDIANS.

SIR,—Your readers who are interested in the midwives question will be pleased to hear of the action of the Local Government Board towards Boards of Guardians who propose to employ certificated midwives. The following is from the *Leicester Daily Post* of October 9th:

The Clerk read a letter from the Local Government Board respecting the appointment of Nurse Masters as a midwife at a fee of 5s. a case, in which it was said: "The Board direct me to state that in every case in which an order is given by the relieving officer for the attendance of Nurse Masters, with a view to her acting as midwife nurse, they consider that an order should at the same time be given by the relieving officer for the attendance of the district medical officer, and that he should attend in accordance with the regulations under which he holds office, and should receive remuneration for the case. The Board request that the Guardians may be desired to direct the officers concerned accordingly."

Whatever may be thought of the necessity or otherwise of midwives in private practice, surely all doctors must agree that official bodies like Boards of Guardians should not employ unqualified medical practitioners.—I am, etc.,

Leicester, Oct. 10th.

REGINALD PRATT.

THE DISCUSSION ON FRACTURES OF THE NECK OF THE FEMUR AT THE LONDON MEETING.

SIR,—In the discussion on the above subject, at which I was unable to be present, Mr. Mayo Robson is reported to have said that the treatment which I advocated in a paper recently published, and to which Sir William Stokes and Mr. Bryant had referred, namely, breaking down the impaction under anaesthesia, "had, in Mr. Robson's experience, often been adopted before." I shall be much interested if Mr. Robson will refer me to published reports or give details of any cases which have previously been intentionally treated in this manner, for I was under the same impression as Sir William Stokes, who in his reply at the close of the debate remarked that "he was not aware, from any published writings, that the Leeds school had anticipated Mr. Southam in laying down the principle of disimpaction."—I am, etc.,

Manchester, Oct. 18th.

F. A. SOUTHAM.

THE MALARIAL PARASITE.

SIR,—The *BRITISH MEDICAL JOURNAL* of August 24th, which arrived by the mail of last week, contains a leading article devoted to a condemnation of an address which I delivered before the Calcutta Medical Society in February last. The following seems to be the chief grounds of your complaint.

You appear to disapprove, in the first place, of "warlike official titles" being affixed to the names of members of the Indian Medical Service who like myself have spent nearly the whole of their time in civil employment. You do not seem to have grasped the facts that the Indian Medical Service is essentially a civil one, that the prizes in the civil department form the chief inducement to enter the service, and that we had no choice or voice in the selection of the titles under which we serve. They came to us as a sort of reversion from the sister service, and it seems somewhat inconsistent in the Editor of the *BRITISH MEDICAL JOURNAL* to decide the titles which he is believed to have been largely instrumental in obtaining for that service. Neither is there anything very extraordinary in medical officers of the Indian army holding permanent appointments in the civil department. Military officers are to be found in all civil departments in India, as in the police, the public works, and even in the Civil Service itself in non-regulation provinces. And it is vain to call out about it, as the formation of a reserve of medical officers in this very way is part of a wise and determined policy of the Government of India; and it is not easy to understand how the possession of military titles can affect the efficiency of the officers so employed.

You are good enough to allude to me as having been "for many years chiefly, if not wholly, a highly successful medical practitioner." I object to this as being a wholly inadequate and misleading description of even my present position in Calcutta, which comprises the executive and medical superintendence of a large hospital, besides other official duties which I need not detail. It is true that it is one of the Calcutta appointments to which is attached "the privilege of private practice." But you can have read my address with scant attention to have been able to take "the anomalous relationship of army medical rank to much more lucrative and preoccupying civil medical practice," as representative in any way of my past services in Government employment, or of the lot of civil surgeons generally. I detail in my address official duties which occupied me for eight hours out of each day when I was civil surgeon of Dacca, and the absence of private practice, except in the Presidency towns, is a universal subject of lament throughout India.

You say that the claims I make for scientific research by members of the Indian Services show that I could not have read Mr. Ernest Hart's address, in which the work of the men I mention is acknowledged. I confess that this is true. I was not even aware that it had been printed; and it certainly does not appear in the *Transactions of the Indian Medical Congress*. I, however, heard his address delivered, and I apologise if I am mistaken in my belief that the address as delivered did not contain any of the qualifying expressions which you now quote. My recollection is that he stated without qualification that "India had contributed nothing but confusion to the advance of scientific medicine;" and I must ask to be excused if I persist in saying that Mr. Hart not once, but repeatedly, told us that the only way of diagnosing malarial fever was by the microscope, and that it should be done in every case. I find that my recollection is confirmed by that of my friends, and the impracticability of the information was at the time on every tongue, and evidenced Mr. Hart's inability to gauge the proportions of the problem with which we have to deal in India.

You question the correctness of the advice I gave as to the best time in the fever cycle for the examination of the blood with a view to finding the malarial parasite, and you quote Mannaberg against me. Allow me, on the other hand, to quote from Marchiafava and Bignami. I regret that I am obliged to do so in the original. At page 10 they say: "Alcune ore dopo l'accesso febbrile si vedono nei globuli rossi i plasmodi," etc.; and at page 53: "Se si esamina il sangue nell'acme dell'accesso, si trova il reperto costituito di piccole amebesenza pigmento, etc....nel periodo di preparazione del nuovo accesso ha luogo, d'ordinario, una notevole diminuzione della quantità del parassiti, nel sangue preso dal dito," etc., which is entirely in accord with my advice to beginners to examine the blood of the finger at the end of the hot stage, during the sweating stage, and in the early part of the apyrexial period; and I should venture to think, though I apologise, of course, for the temerity of the suggestion, that clinical experience in India might be a safer guide to the beginner in India than even such authorities as Mannaberg and Marchiafava, especially where they disagree with one another.

You accuse me not only of "many errors of fact," but of "conveying an exaggerated idea of the difficulties of finding the malarial parasite, an idea calculated to deter the modest worker from attempting it." I specially guarded myself against this inference, and warned him "if he wishes not to be discouraged beyond all hope not to begin his investigations in January, February, or March, when a large proportion of our fevers appear to be of non-malarial character, and when the proportion of cases in which the organisms are invisible in blood taken from the finger is very large. Let him wait until September, and he will then begin the study at a time when the organisms are numerous, and frequently to be found."

"During this period let him examine as many specimens as possible, so as to familiarise himself with their various appearances, so that he may not miss seeing them when they are there."

I still regard this as most excellent advice, and I am glad to be able to agree with you that the parasite requires to be looked for in the right way, and in the right way is employed,

and the parasite is there, a child (nay, even a member of the Indian Medical Service) might see it.—I am, etc.,

A. ODOMS, M.D.,
Surgeon-Lieutenant-Colonel; Surgeon Superintendent
of the European General Hospital, Calcutta.

Calcutta, Sept. 14th.

The address in question was published by Messrs. Thacker and Co. in Calcutta immediately after delivery, and Dr. Crombie confirms our impression that he had not read it. In reference to the paragraph on malaria in Dr. Crombie's letter we would remind him that both he and we were discussing the best time in the fever cycle for a beginner in malaria blood examination to select for finding the parasite; and we quoted Mannaberg, who, along with Laveran and many others, distinctly recommends the end of apyrexia and the commencement of pyrexia for this purpose. Dr. Crombie notes Marchiafava and Bignami (pp. 9 and 56, *Sydenham Society's Translation*) to show that the parasites are most numerous during pyrexia and fewest during apyrexia; and he would have us think that Mannaberg and these authors are in disagreement. But if he would study Mannaberg he would find that this authority and all other good observers concur in this particular point. This, however, is not the question at issue. What is wanted is the best time for the beginner to look for the parasites, not the time when they are most numerous. These are two very different things. It is quite true that many more parasites can generally be seen by the expert during fever than during late apyrexia; but it is equally true that during fever the vast majority of the parasites—the new generation in fact—are then so minute—little more than specks in the corpuscles—that they are hard for one unaccustomed to the work to recognise, so that at this stage the beginner, and even the expert, has often to fail back on pigmented leucocytes, or, according to the type of the fever, on any crescentic or flagella-forming spheres that may chance to be present for a diagnosis. But about the end of apyrexia and the beginning of the fever paroxysm the parasites, though fewer in number, are pigmented and have grown so large that a "child might see" them, and hence this is the most suitable time for the beginner to endeavour to find the malaria parasite. A full-grown hen is a much more conspicuous object than a newly hatched chicken—a self-evident proposition as applicable to the malaria parasite as to the barn-door fowl.

If Dr. Crombie had quoted the passages from Marchiafava and Bignami *in extenso*, and had translated them, his readers would have had no difficulty in reconciling what he would consciously have them believe is a discrepancy between these authorities, Mannaberg, and ourselves. A mutilated quotation gives an incorrect impression. In other respects this letter does not correctly represent the effect of our leader, with which it may be compared.

LONGMORE'S GUNSHOT INJURIES.

Sir.—In the last paragraph of the note you appended to my letter which appeared in the BRITISH MEDICAL JOURNAL of October 12th, you quote me as having said that "we are already supplied with ample statistics as to the effects of the use of small arms." What I did say was that we had full statistics as to the effects of small arms of the Martini-Henry pattern. As regards the wounds rifles produce, these weapons may be divided into two classes: one comprising the modern rifles of small calibre, and the other all the older rifles firing the elongated cylindro-conoidal bullet—the Martini-Henry, Snider, Gras, Chassepot, needle gun, Minié, etc. The point I wished to make in my remarks on Sir Thomas Longmore's second edition was that it contained the ample statistics which are available as to the use of rifles of the second category, but that the omission of statistics of the effect of the use of modern rifles was not a defect, or that it was unavoidable, for the reason that none existed. As regards the Balmaceda rebellion in Chili, we have no information as to the effect of the small boxes used there, except some general statements which are now known to be, in great part, inaccurate. I certainly would not "seriously maintain that the work was complete" if it omitted important statistics which were available, but I do not consider that it does so.—I am, etc.,

W. F. STEVENSON,
Professor of Military Surgery, Army Medical
School, Netley.

October 14th.

THE ANDREW CLARK MEMORIAL FUND.

Sir.—In the BRITISH MEDICAL JOURNAL of October 12th you have rightly stated the cause of the failure of this fund—that the profession had not an opportunity of expressing its wishes on the form which the memorial should take.

Clinical medicine was a strong point with Sir Andrew; any scheme which would have contributed to the advancement of its study would have been dear to his heart; therefore may we not hope at the eleventh hour that a meeting of medical men will be called in order that Sir Andrew Clark's memory may be perpetuated by some worthy memorial?—I am, etc.,

Warwick Square, S.W., Oct. 11th.

THOS. LANGSTON.

INADEQUATE SALARIES OF PUBLIC HEALTH APPOINTMENTS.

Sir.—I should very much like to enlist your help in trying to induce those of the profession who have taken up public health work to make a stand once for all against such sweating as appears to be contemplated by the East Sussex County Council, judging from their advertisement in the BRITISH MEDICAL JOURNAL of October 5th. The JOURNAL has of late said much to encourage the medical men of Cork and elsewhere in their resistance to the grinding terms which the clubs and medical aid societies have sought to impose. Is this bargain proposed by the East Sussex County Council not quite as stringent?

This proposed appointment in East Sussex is unfortunately not the first of its kind. There are others, of which the remuneration is on much the same scale, which have been sought after and accepted even by men of some standing in the profession, and the need is therefore the greater that some expression should be given to the opinion held by, I trust, the vast majority of the profession, that all those who apply for such posts show an utter want of respect for themselves and their profession.

The appointment of a county medical officer of health on such terms must mean one of two things as regards the County Council: either that they are quite ignorant of the work to be done by a county medical officer of health, which is the more charitable supposition, or that they do not wish their officer to be too active in the discharge of his duties; but as regards the medical officer of health appointed the former excuse can scarcely be applicable, and he must be undertaking the office well knowing that the salary is totally inadequate to the work which ought to be done.

I have laid stress upon the injury to the profession which such an appointment will give rise to, but it is evident that the injury to the public will be no less. The medical work now being done by the medical officer of health in a few of the more advanced counties where they are properly remunerated can evidently not be looked for under such an arrangement as that proposed by the East Sussex County Council.

It may be that this advertisement is merely a matter of form, and that it is the intention of the County Council to combine the post of county medical officer of health with some of those for local sanitary districts, but if so it would have been only fair to make the facts known, and even so the above remarks apply to other similar posts in other counties.

It is, Sir, I hope you will agree with me, high time that the profession should make some protest against such treatment.—I am, etc.,

October 9th.

PUBLIC HEALTH.

* * The duties of the appointment appear to be those ordinarily assigned to the medical officer to a county council, and the "honorarium" offered is one hundred guineas a year and travelling expenses.

The proprietors of the *Provincial Medical Journal* have decided to discontinue its publication after the December number. Dr. T. M. Dolan, the editor of the moribund periodical, proposes to provide a substitute in the form of a monthly journal of medicine and surgery, to be entitled *The Scalpel*.

A monument to Duchenne, of Boulogne, will shortly be erected in the Salpêtrière. It is the work of M. Desvergues, the sculptor, and M. Debré, an architect. It is also proposed to erect a memorial to Duchenne in his native city of Boulogne.

OBITUARY.

THOMAS KEITH, M.D., LL.D. EDIN., F.R.C.S. EDIN.

THE death of Dr. Thomas Keith, which occurred on October 9th, though a source of deep regret to his professional friends and an irreparable loss to the profession generally, was by no means unexpected. For a considerable time past Dr. Keith had practically retired from active professional life owing to the advances of an old-standing disease.

Thomas Keith was born on May 27th, 1827, in his father's house at St. Cyrus (or Ecclesraig) in Kincardineshire, within six miles of Montrose, in Forfar, from which it is separated by the estuary of the North Sea. Dr. Keith's grandfather, the Rev. Dr. Skene Keith, made himself celebrated by an important work, *The Agriculture of Aberdeenshire*. His father was the Rev. Dr. Keith, of St. Cyrus, who wrote several theological works and pamphlets still well known in Scotland; he died, aged 80, sixty years after his book on *Forfar* appeared. His mother was sister to Sir Thomas Keith.

Dr. Keith received his early education at Aberdeen Grammar School and Mariachal College. Dr. George Keith, his brother, informs us that "in Aberdeen, while still a boy, he began to be troubled with passing small calculi from the bladder, which later were found to consist of pure cystic oxide. One of them stuck in the urethra, and had to be removed by operation. To try to cure the ailment he got large quantities of carbonate of soda, and this he blamed for upsetting his stomach and for much of his subsequent miseries." In 1838 Mr. Syme unsuccessfully performed lithotomy. In 1841 he opened the bladder but found the stone in the urethra. In 1849 a large abscess formed behind the kidney. Mr. Skene Keith opened it and the sinus never closed. In 1851 a small sharp stone lodged about the neck of the bladder and caused bleeding. The bladder filled with clot; the stone was ultimately passed. Thus Dr. Keith passed a life of feeble health varied only by attacks of acute agony; yet his courage never failed him and he worked and attained fame in spite of intractable infirmity.

His medical education was entirely conducted at Edinburgh, where he was apprenticed to Professor (afterwards Sir) James Simpson, for whom he did much work. He was, his brother informs us, the last medical apprentice in Edinburgh. Dr. Keith acted as Resident Surgeon to Mr. Syme in the Edinburgh Royal Infirmary. He was much attached to Mr. Syme, and declared to the last that he was indebted to that great surgeon for sound principles in the treatment of surgical cases, especially simplicity, painstaking, and absolute cleanliness. The attachment was mutual, and continued till Mr. Syme's death. Dr. Keith had previously attended the second Mrs. Syme during a long illness.

After qualification, Dr. Keith accepted the appointment of Surgeon to the Hon. Wm. Abercromby, British Ambassador at the Courts of the King of Sardinia, at Turin, where he remained two years. During his stay in the Italian city he published a paper in one of the local journals on the evils of the then prevailing system of copious blood-letting. His action, which posterity can more than justify, caused him great trouble, and all the profession in Turin, except one of the principal surgeons, treated him with marked discourtesy. Afterwards he became a partner in the practice of his brother, Dr. George Skene Keith, and remained for twenty years in partnership, the surgical work in the practice being placed almost entirely in his hands.

Although in his first years he practised obstetrics with success, yet from an early period he devoted himself to general surgery, in which he had a large practice. Ultimately, however, he confined himself to gynaecological surgery. It was in 1862 that Keith performed his first ovariectomy, having seen how successful Sir Spencer Wells had been in his series of operations commenced four years previously.

Dr. Keith removed for the first time a cystic ovary, and followed up his first ovariectomy by a long and successful series of abdominal sections. He strongly believed in well-trained assistants. Dr. James Gibby, and afterwards Mr. Skene Keith, were on that account chosen for co-operation. Believing that general hospitals were not, when he began his

labours, sufficiently aseptic, Dr. Keith, at a personal cost of over £3,000, converted into a hospital a house in Great Stuart Street, Edinburgh, and there many of his earlier operations were undertaken.

It is needless to speak of the success which attended his work as an ovariectomist. Though the only successful performer of this operation in the city at that time, he extended the benefits of his little hospital to both rich and poor alike. In 1870 his merits as an operator had become so well recognized that the managers of the Infirmary acknowledged his position by appointing him extra-surgeon for ovarian disease, and he filled this post for eighteen years, resigning it only on his removal to London. In this capacity he did much to increase the fame of the Edinburgh Hospital and School. He was in the habit of allowing a select number of students to see his operations, and these opportunities were most eagerly sought after, and highly prized by students and practitioners alike.

During these years of active work in Edinburgh, Keith not only perfected the operation of ovariectomy, but applied himself to reducing the mortality of hysterectomy, and his modifications were so eminently successful that before leaving the Edinburgh Infirmary he had made the operation comparatively safe. In 1888, out of 33 cases recorded there were only 3 deaths.

Dr. Keith was for some years Extra-examiner in Surgery in the University. In 1888 he resolved to go to London, and the managers of the infirmary recognised the importance of his services by acknowledging in a very appreciative minute their sense of the greatness of their loss.

While in Edinburgh he built up for himself a world-wide reputation, and his professional journeys were not confined to Great Britain, but included various parts of Europe and America. His departure from Edinburgh was deplored not only by the entire profession, but by a large circle of friends and patients. Of a very retiring disposition, and disliking all fuss and ostentation, Dr. Keith did not take a very active part in Edinburgh society. He belonged to all the scientific societies in the city, though he did not take a prominent part in any of them. All his magnificent work was done in a quiet unassuming manner.

After Dr. Keith and his son, Mr. Skene Keith, came up to London, they continued to practise abdominal sections with great success. The electrical treatment was extensively tried in cases of fibroma, and Dr. Keith found after long experience that though electricity cannot "disperse" a fibroid, it places a patient who has a fibroid that causes pain or trouble in the position of a patient who has a fibroid that is in no sense a source of danger or suffering.

For the last three years Dr. Keith's infirmities prevented him from doing any active work. In the course of the summer he visited his home near Montrose, and returned to London feeling much better; but the heat seems to have been the direct cause of a debility which increased till it proved fatal early on the morning of Wednesday, October 9th. Dr. Keith dying without any suffering at his residence in Charles Street, Berkeley Square. He was buried last Friday in Kensal Green Cemetery.

Dr. Keith married Miss Johnston, first cousin to the wife of Sir James Simpson. Mrs. Keith and their six children all survive him. Three out of Dr. Thomas Keith's six brothers entered the medical profession like himself. One survives, Dr. George Skene Keith, his former partner, who qualified over seven years before his now deceased brother, and who, in his 78th year, lives in retirement at Currie, near Edinburgh; another brother died, aged 70, in Algiers. The other brothers who became medical men both died young.

Dr. Keith was well known as a writer. His early successes in ovariectomy were published in the *Edinburgh Medical Journal* between 1867 and 1874. His *Contributions to the Surgical Treatment of Abdominal Tumours* relate to that still unsettled question, the treatment of uterine fibroids. The first part (published in 1868) treated of hysterectomy; the second appeared a few years later, and related to electricity as a therapeutic agent in fibroid disease. A large number of papers on these two subjects are to be found in past numbers of the *British Medical Journal*, especially in 1887 and 1892.

Dr. Keith certainly showed no approval of the principles

and practice of certain Continental authorities who advocate very early vaginal hysterectomy for fibroid, on the score that the tumour may grow bigger and give trouble or even cause danger. "To the woman with a fibroid uterus, who has passed the best of her years in weariness and pain, middle age brings relief, and old age may be spent in peace," writes Dr. Keith. "Hence the difficulty in knowing how far we are justified in advising interference for a disease that troubles for a time, though it rarely kills." He knew as all the profession should know, that many fibroids fail even to trouble for a time.

In 1894 much of Dr. Keith's latest experience was embodied by his sons in their work, *A Textbook of Abdominal Surgery*. The authors admit that electricity is in no sense a panacea, and deprecate over-zeal in any kind of operative work.

The fame of Dr. Keith brought him many honorary distinctions, hardly necessary to recapitulate in the case of a man whose name was so well known. He was made an LL.D. of the University of Edinburgh on the occasion of the tercentenary, and received the same honorary degree from Aberdeen. He was an Honorary Fellow of a large number of British and foreign societies. In the United States, in particular, he was deeply respected, as reference to the American medical papers will amply prove, for his professional merits, his courtesy, and his impartial judgment of foreign authorities on his speciality.

Dr. Keith took a lively interest in many social questions, though the feeble health which hindered him throughout his career quite precluded him from appearing as a publicist. Early in 1881 an attempt was made to gain him over to the antivivisection cause. An enthusiast called upon Dr. Keith, who expressed an opinion that a certain series of experiments on animals were of questionable value. After the manner of such persons, the interviewer misrepresented Dr. Keith's statement at a public meeting. Dr. Keith replied in a very strongly worded paragraph to be found in the *JOURNAL*, vol. i. 1881, p. 138. He expressed his indignation that a gentleman had been misled at the meeting in question for honestly declaring that many sham humanitarians thought as much of their overfed, wheezing, pampered cats and dogs as of human life. He concluded by deprecating the degradation of science involved in a Parliamentary licence.

Sir Spencer Wells writes: I willingly comply with the Editor's request that I should write something as to my appreciation of the work of my old friend Thomas Keith. Latterly, although he has been practising in London, I have not seen so much of him as I did many years ago in the early days of ovariectomy. We then saw a good deal of each other. He was in Edinburgh while I was in London, but he often came up and I occasionally visited him in Edinburgh. We were then, and have been since, on the most friendly terms. We compared notes together, and gave each other what help we could. I had done eight cases of ovariectomy when Keith began, and he soon afterwards sent me a lady from the West of Scotland, whom he subsequently told me was the first case for which he received the usual fee. She wished me to go to Scotland and operate, but I advised her to leave herself in Keith's hands. The operation proved quite successful, and I believe she is still alive. This case increased our intimacy, which then went on without interruption as long as he was at work.

When Duncan and Lister came to London, Keith felt lonely in Edinburgh, and soon followed them; but his health failed, and although he was enthusiastic in his treatment of uterine tumours by electricity, I doubt whether his hopes and expectations were fully realised. Between two and three years ago he became ill, and went to his native place in Scotland, of which he was very fond, and where his health improved, and only returned to London two or three weeks before his death. It is nearly three years since he did his last ovariectomy, and after that time we very seldom met.

He operated between 500 and 600 times, and his success was very great. He was one of the earliest, and has been one of the most successful operators. He was thoroughly honest, and was to be believed in every word that he said or published. He was most cautious in giving an opinion, and equally so in acting upon it. I was much amused some thirty years ago when I asked him to see a lady

in London, of whose case I was doubtful. I said, "Shall I operate or not?" He replied, "She is a nice-like woman." I said, "Yes, very; but shall I operate?" He said, "She is a very nice-like woman;" and that was all he would say. But she got well, and is still alive. I have often laughed with him since over his cautious judgment of the case.

He thought I was not sufficiently favourable to a specialist's views; but I met several patients soon after his arrival in London. Some of the cases are quoted in his book. The results were encouraging, but not so favourable as I had hoped. During his illness his son continued the treatment, but I think with more confidence in surgical than electrical methods. Another son, now in London, is devoting himself to obstetric practice.

I have been trying in vain to put into words my appreciation of Keith as a friend and as a professional brother, and I am driven to quote a few sentences which I once addressed to medical students from Dr. James Jackson's *Letters to a Young Physician*. Writing of Dr. Holyoke, the first President of the Massachusetts Medical Society, he said: "It was on account of his professional merit that he was thus honoured, but all the more that his whole character was most worthy of respect. He had the delicacy of taste, as shown in his manners and general bearing, which grew out of a fine organisation and of a cultivated mind. His conceptions were clear and his memory strong, though, like other old men, he lamented its decay in the latter part of his life. He had not lost it, however, as was shown on the day which completed his 100 years, and when he began a new century. His reputation was unspotted. I never heard anyone hint at even any moral error in his life." I might easily say of Keith all that Jackson wrote about Holyoke. I should like to quote more from Jackson's letters, but I know how fully your space is occupied, and must be content to refer your readers to his book published at Boston in 1855, entitled *Letters to a Young Physician just Entering on Practice*, and with a few words from the preface dedicate it to Dr. Warren, with which I may fittingly conclude this tribute to the memory of a very dear old friend. Jackson writes:

"You and I began our active lives in this city nearly at the same time. It was when Boston had about one sixth of its present population, and I suppose much less than a sixth of its present wealth. We were so circumstanced as to be peculiarly rivals. Our business led us across each other's paths every day for a long series of years. What one gained the other seemed to lose. It would have been very easy for us to have got up a pretty quarrel at any moment; and, having once begun, we might each have got partisans, and all the usual entanglements to such cases appertaining might have followed. Happily we pursued a different course. We met together with the feelings we had as fellow-students. We took much delight in consultation and discussion on professional subjects, and were ever ready to help each other. We have, indeed, maintained a strong personal interest in each other's welfare and promoted each other's happiness. We do not resemble each other in temperament and cannot see all things alike. From this cause and not always looking at objects from the same point of view we often differed in opinion. But we have always agreed to differ. We have not often disputed and never have quarrelled on account of this difference of opinion nor on any other account. In our intercourse with the stock each has given the other credit for what was good in him instead of studying and publishing the other's faults. In every work for the promotion of medical science or for elevating the profession we have co-operated heartily, neither of us trying to push the other aside. And thus it is that being now as regards age in the front rank of our profession we have continued to this day on terms of intimacy and friendship. This is something to rejoice in, and something for which we may properly thank God, and I know you will join me in giving thanks reverently.

"As we are nearing the end of our journey I hope I may be excused for stating this experiment and its results. I would show to young men how grateful those results are. I can say to them that our interests have been promoted by our friendly treatment of each other; that each of us has gained by it much more than either of us could have done by the sharpest quarrels. If they believe me, any two of them

zymotic death-rate averaged 3.7 per 1,000. The lowest zymotic rates during last quarter in the various sanitary areas were 1.2 in Lee, 1.3 in Plumstead, 1.7 in London City, 1.8 in St. Martin-in-the-Fields, and 1.9 in St. George Hanover Square and in St. James Westminster; while the rates ranged upwards to 6.1 in Poplar and in St. George Southwark, 6.2 in Bethnal Green, 6.3 in Shoreditch, 7.7 in Mile End Old Town, 7.8 in Limehouse, 9.3 in St. George-in-the-East, and 13.4 in St. Luke.

Thirty-one deaths from small-pox of persons belonging to London were registered during the three months ending September last, of which 6 belonged to Camberwell, 4 to Whitechapel, and 2 each to Strand, Shoreditch, Bethnal Green, Lambeth, and Plumstead sanitary areas. Measles showed the highest proportional fatality in Rotherhithe, St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Battersea, and Camberwell; scarlet fever in Strand, Shoreditch, Whitechapel, St. George-in-the-East, Limehouse, and Poplar; enteric fever in St. Luke, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Camberwell, and Greenwich; whooping-cough in Poplar, Clerkenwell, St. Saviour Southwark, Newington, and Lambeth; enteric fever in Hackney, Shoreditch, and St. George Southwark; and diarrhoea in Rotherhithe, St. Luke, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, St. Saviour Southwark, and St. George Southwark.

During the quarter ending September last 1,631 deaths from phthisis were registered in London, equal to an annual rate of 1.5 per 1,000. Among the various sanitary areas the lowest phthisis death-rates were recorded in Fulham, Hampstead, Stoke Newington, Wandsworth, and Lewisham; the highest rates in Westminster, Strand, Holborn, Clerkenwell, St. Luke, Whitechapel, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, and St. Olave Southwark.

Infant mortality in London last quarter, measured by the proportion of deaths under one year of age to registered births, was equal to 20 per 1,000; this rate exceeded that recorded in the corresponding period of any year since 1887, and was 29 per 1,000 above the mean rate in the third

quarters of the ten preceding years. Among the various sanitary areas the rates of infant mortality were lowest in St. George Hanover Square, St. James Westminster, Islington, Stoke Newington, Rotherhithe, Lee, and Plumstead; while they showed the largest excess in Holborn, Clerkenwell, St. Luke, St. George-in-the-East, Limehouse, St. Saviour Southwark, and St. George Southwark.

THE MANAGEMENT OF PAUPER LUNATICS.

LEX writes: 1. A man is sent to the workhouse, of which I am medical officer, and placed in the asylum before my arrival without any detention order. He has previously been in more than one asylum, and has lately been drinking and is somewhat excited. There is not sufficiently apparent proof of insanity to warrant my certifying him at once, but I think it desirable to keep him under observation for a week or two. Can I (under Section 21 of the Lunacy Acts Amendment Act, Sub-section 2) give a detention order for fourteen days without a magistrate's or other medical man's order? 2. A certified lunatic in the workhouse asylum is becoming more and more restless and troublesome; he is suffering from chronic mania, and, though not dangerous to himself or others, ought to be removed to an asylum where he can receive more systematic treatment. A magistrate refuses to sign the order, on the ground that the patient "has no delusions."

1. No. 2. "Lex" can do no more than make a full representation of the facts to the justice—that is, having once freed himself from responsibility by doing his part under Sections 14 and 16 of the Lunacy Act, 1880.

DUTIES OF A DISTRICT MEDICAL OFFICER.

H. T. asks the following four questions: 1. When a medical order has been granted does it continue in force for the current illness only or should it be renewed after any specified time? 2. Is it necessary to

MEDICAL NEWS.

THE ninth French Congress of Surgery will be held in Paris from October 21st to 26th under the presidency of Professor Boscq.

We are pleased to announce that Mr. Trimmer has sufficiently recovered from the injuries inflicted on him by the miscreants who robbed him in Lincoln's Inn Fields, to be able to resume his duties at the Royal College of Surgeons.

THE late Mr. Charles Cardale Babington, Professor of Botany in the University of Cambridge, has bequeathed the whole of his valuable collection of plants to the University. This is in addition to his botanical library, which was presented to the University by the late professor in June, 1888, and is now in the University Museum.

THE first meeting of the Matrons Council for the winter session will be held at the rooms of the Medical Society, Chandos Street, Cavendish Square, on Thursday, October 24th, at 5.30 P.M., when Miss Isla Stewart, Matron of St. Bartholomew's Hospital, will open a discussion on a Uniform Curriculum of Education for Nurses.

THE winter course of Lectures and Demonstrations given by the staff of the Hospital for Consumption and Diseases of the Chest commenced on Wednesday, October 9th, when Dr. Douglas Powell gave a lecture on Angina Pectoris. Other lectures are given on succeeding Wednesdays until December 18th.

EDINBURGH ROYAL INFIRMARY.—The following appointments have been made by the managers:—*House-Physicians*: Drs. Joseph E. Bowes, Frank W. B. Fitchett, John Forbes, William J. Garbutt, David M. Hutton, Ernest M. Skote, and Frederick Skay Stanwell. *House-Surgeons*: Drs. Charles J. Hill Aitken, H. P. Barlow, W. H. Bryce, Henry F. J. Simson, and David Waterston.

At the Quarterly Court of the Directors of the Society for Relief of Widows and Orphans of Medical Men held on October 9th, the President, Sir James Paget in the chair, two new members were elected. There were no fresh applications for grants; applications for continued assistance were read from 51 widows, 8 orphans, and 4 orphans on the Copeland Fund, and it was determined that a sum of £1,182 10s. should be distributed at the next Court, subject to the report of the visitors. A sum of £452 was voted to be given at Christmas, namely, £8 each to the 51 widows, £3 each to the 8 orphans, and £5 each to the 4 orphans on the Copeland Fund. A grant of £20 towards the self-maintenance of an orphan was made, and a special grant of ten guineas was given to a widow. The expenses of the quarter amounted to £55 2s.

THE FIFESHIRE MEDICAL ASSOCIATION.—At the last meeting of this Association, held at Kirkcaldy, the President (Dr. J. Sutherland Mackay) delivered an address upon Historical Pathology, with special reference to the "Black Death" and the Cholera Epidemic in Spain of 1885, the latter being described from personal experience. Reference was then made to the high mortality from preventable diseases in Great Britain, and an appeal made to assist in diminishing this waste of life. The President then moved a resolution to the effect that the holder of a "Medical Aid" Society's appointment should be ineligible for membership. After some informal discussion, entirely in favour of the proposition, it was determined to make some further inquiries as to the attitude of the General Medical Council in respect to such appointments. The following officers were elected for the ensuing year:—*President*: Dr. William Mackay, Falmouth, Largs. *Vice-President*: Dr. Aitken, Buckhaven. *Honorary Treasurer*: Dr. A. G. Macdonald, Cupar. *Honorary Secretary*: Dr. Douglas, Cupar. *Councillors*: Drs. D. Hamilton, Kyle, and Hurlington, St. Andrews, and Dr. Hamilton, Guardbridge.

ENTRANCE SCHOLARSHIPS.—At St. George's Hospital an entrance scholarship in Arts of the value of £145 has been awarded to Mr. Thomas Clegg Farnham, and scholarships in Arts of the value of £50 to Mr. Henry Ayrton Chaplin, Mr. Edw. Frank Clegg, and Mr. Lawrence Jones. Entrance scholarships in Science of the value of £85 were awarded to Mr. Herbert Springfellow Pendlebury, B.A., of Pembroke

College, Cambridge; to Mr. Henry Goodridge Deller, B.A., of Trinity College, Cambridge; and to Mr. John Howell Evans, B.A., Oxford. The two last named were bracketed equal, but owing to the excellence of their papers a full scholarship was awarded to each.—At King's College, London, the Warneford Scholarship of £25 for three years has been awarded to Mr. R. N. Batterbury, and scholarships of similar amount for two years to Mr. J. G. Pritchard and Mr. H. G. Wright. The Clothworkers Company's exhibitions have been awarded to Mr. C. F. Mott (£30 for two years) and Mr. R. H. C. Gompertz and Mr. C. L. Cartwright (£20 for two years). The Sambrooke Exhibitions have been gained by Mr. N. L. Stuart (£60) and Mr. A. C. Williams (£40).—From a revised list issued by St. Mary's Hospital Medical School it appears that an exhibition of £25 has been awarded to Mr. A. Ferguson MacCallan, B.A., Christ's College, Cambridge, and that the three Natural Science Scholarships of 50 guineas each were awarded to Mr. E. W. Holyoak, Mr. A. F. Hayden, and Mr. J. Tattersall.

MUNICIPAL VACANCIES.

The following vacancies are announced:

BELGRAVE HOSPITAL FOR CHILDREN, 77 and 79 Gloucester Street, S.W.—Surgeon to Out-patients; must be F.R.C.S. Eng. Applications to the Honorary Secretary by November 1st.

Parker: Sequel to a case of Removal of the Right Patella; recurrence after six years in the iliac glands; death. Dr. A. Wilson: The Treatment of Acute Pleural Effusion by Incision. Mr. C. Mansell Moullin: Suprapubic Cystotomy and Prostatectomy in Cases of Multiple Growth.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Craig: Stupor, Catalepsy, Katatonis, Dementia.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

- FITCH.—On the 4th inst., at Churchgate House, Chadderley Corbett, Kidderminster, the wife of Dennis Fitch, M.R.C.S., of a daughter.
- HUDSON.—On Friday, the 11th inst., at 16, Harley Street, Cavendish Square, W., the wife of C. E. Leopold B. Hudson, F.R.C.S., of a son.
- LANGFORD-JONES.—On the 6th inst., at Tan-y-Graig, Bangor, the wife of Alderman E. Langford-Jones, M.R.C.S.Eng., Mayor of Bangor, of a daughter.

MARRIAGE.

SEATER-GILL.—On October 14th, at Linkinhorne Parish Church, Cornwall, by the Rev. Norman Leslie Jackson, M.A., Howard Seater, M.R.C.S., L.R.C.P.Lond., second son of Daniel Seater, M.A., of Obverse Hall, Plymouth, to Susanna Josephine (Phenie), younger daughter of the late Joseph Gill, of Bath. No cards.

DEATH.

THOMPSON.—On September 26th, at Clyde House Cradley, of Bright's Disease, Wesley Hayes Thompson, M.D.Durham, L.R.C.P., L.R.C.S.Eng., aged 5 years.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS RESPECTING EDITORIAL MATTERS SHOULD BE ADDRESSED TO THE EDITOR, 428, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 428, Strand, W.C., London.

AUTHORS DESIRING REPRINTS OF THEIR ARTICLES PUBLISHED IN THE BRITISH MEDICAL JOURNAL ARE REQUESTED TO COMMUNICATE BEFOREHAND WITH THE MANAGER, 428, Strand, W.C.

CORRESPONDENTS WHO WISH NOTICE TO BE TAKEN OF THEIR COMMUNICATIONS SHOULD AUTHENTICATE THEM WITH THEIR NAMES—OF COURSE NOT NECESSARILY FOR PUBLICATION.

CORRESPONDENTS NOT ANSWERED ARE REQUESTED TO LOOK TO THE NOTICES TO CORRESPONDENTS OF THE FOLLOWING WEEK.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN ORDER TO AVOID DELAY, IT IS PARTICULARLY REQUESTED THAT ALL LETTERS ON THE EDITORIAL BUSINESS OF THE JOURNAL BE ADDRESSED TO THE EDITOR AT THE OFFICE OF THE JOURNAL, AND NOT TO HIS PRIVATE HOME.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

SUFFOLK asks what St. Polten's lotion for eczema is composed of.

M. O. H. asks what are the best books to get for giving the nursing lectures for women under St. John Ambulance.

SHROBORN asks for advice as to the drugs, clothing, etc., to take to South Africa. Any other information will be appreciated.

M. D. asks how hot salt water baths may best be obtained in London for a patient; and, if these cannot be obtained, how best to substitute them at home.

MEMBER will be much obliged for information regarding the use of electricity in stimulating the growth of hair, in premature baldness for example, a cheap but effective battery; kind and strength of current to be used, and method of application of the poles.

NAILED BITING.

MEMBER OF R.M. ASSOC. asks for advice in preventing a girl, aged 10 years, from biting her nails. The child herself is very anxious to stop this evil habit.

PETROLEUM LOCOMOTIVES.

J. O. asks whether the petroleum motor has as yet been applied to tricycles in this country, either instead of or in aid of pedalling. It would be a great boon to many country practitioners in going distant rounds to have an auxiliary power to turn on when the rider is tired, and it probably would not be very prominently in contravention of the Act.

RECOVERY OF SMALL DEBTS.

G. P. asks for experience as to the best method of dealing with small bad debts among the working class. Sums from 2s. 6d. to 2l. are often run up, and I find are very difficult to collect. This is especially the case with the smaller sums, where people have one or two visits only.

AMBULANCE LECTURES.

J. C. G. writes: I have been asked to give some ambulance lectures in connection with the Technical Education Committee, about twelve in the course, what is the best book to recommend my class to read? I have *St. John's First Aid*, but I judge that hardly sufficient for my purpose. Also, where could I hire a manikin to illustrate anatomical lectures, and approximate cost?

*A *Manual of Ambulance*, by J. Scott Riddell, published by Griffin, Exeter Street, is a very good one, but there are many others. We are not aware that any suitable manikins are to be had. Our correspondent is advised to purchase a skeleton, which can be got at Kimpton's, Wardour Street, or many other medical booksellers or instrument makers, at a cost from 25 to 30s. or more. The diagrams published by the Science and Art Department for their lectures, three in number (the Muscles, the Vessels, and the Viscera), will be found useful, cost about 2l. each.

COLLEGE HERALD.

*P. D. asks where he can find a correct heraldic description of the arms of the various medical corporations, such as the Colleges of Surgeons and Physicians, the Faculty of Physicians and Surgeons, Glasgow, etc., or where paintings of their crests could be obtained.

*A note on book with which we are acquainted containing a correct heraldic description of the arms and crests of the various medical corporations. The arms of the Barbers and Surgeons will be found in Mr. Sidney Young's *Arms*. There is a description of those of the Royal College of Physicians in Munk's *Roll*, vol. III, p. 118, and a

woodcut of these on the title-page of the *List of Fellows*. The armorial bearings of the Royal College of Surgeons of England are described and figured in the *College Calendar* as a note to section I of the By-laws. Sir Charles Cameron gives an account of the arms of the Royal College of Surgeons in Ireland in his *History of the College*, p. 68. For an accurate description and for paintings of these coats of arms, our correspondent will probably find it necessary to apply to the secretaries of the various corporations.

TEXTBOOKS OF PHYSIOLOGY.

T. F. writes: I am anxious to re-read the subject of physiology. Would you mention the best book for the purpose—one including the latest discoveries?

*We would recommend our correspondent to read the latest edition of any of the standard works on physiology, namely, *A Textbook of Physiology*, by M. Foster, M.A., M.D., London: Macmillan and Co.; *A Textbook of Human Physiology*, by Dr. L. Landolt and W. Stirling, M.D., 2 vols., London: C. Griffin and Co. (42s.); *An Introduction to Human Physiology*, by A. D. Waller, M.D., London: Longmans, Green, and Co. (18s.); *Manual of Physiology*, by G. F. Yeo, London: J. and A. Churchill. (14s.); *Elements of Human Physiology*, by E. H. Starling, London: J. and A. Churchill. (7s. 6d.) The three last named are works in one volume, and so one of these would probably suit our correspondent's purpose best.

ANSWERS.

H. A. C. should communicate with the authorities of the St. John Ambulance Association, St. John's Gate, Clerkenwell.

CANDIDATES AND FALSE TEETH.

MEDICUS.—False teeth have not hitherto been held a disqualification in candidates for the Indian Medical Service, provided, of course, that a sufficient number of sound natural teeth remain.

THE INUNCTION OF MERCURY.

C. M. J., in reply to "High Peak," recommends the white precipitate ointment of the *London Pharmacopoeia* spread on linen 4 by 3 inches applied to the soles of the feet every morning. This gives no indication of treatment, and is preferable to blue ointment. "C. M. J." adds that he has used it for years.

HOSPITAL APPOINTMENTS.

E. H. C., J. S. B., D. S.—There is very little doubt that if any appointment were made contrary to rules duly passed, in accordance with the deed by which the hospital is incorporated, such appointment would be voidable; but it is probably very rarely the case that rules regarding the appointment of house-surgeons are of such a fundamental nature, or that they are so strictly worded as to make it possible to prove that such an abuse as is described by our correspondent is, in fact, contrary to the deed. Unless the matter were taken up by an influential governor, we doubt whether good would result by any attempt to bring the matter to the test of law.

INDECENT LITERATURE AND THE POLICE.

A CORRESPONDENT has sent us a number of advertisements cut from a local provincial paper, and also a circular from a publisher containing notices of books which he considers, and probably quite correctly, to be of an improper nature. The suppression of the circulation of such literature is a matter of police administration, and, if the police do not see their way to interfere, we apprehend that it is not within our power to take any useful action. Our correspondent sends us also a volume, apparently a reprint of a work issued many years ago, containing a great deal of matter which might pander to the prurient mind. However objectionable it may be that such works should be placed in the hands of the general public, we fear that no remedy is to be found except through the action of the police.

SHIPS' SURGEONS.

SHROBORN R.M.S.P.Co. writes: In reply to "O.M.B.," who inquires about the duties, etc., of a ship's surgeon, I would recommend him to apply personally with copies of his testimonials at the offices of the different shipping companies; a introduction to one of the directors or managers is of great advantage, in fact almost indispensable. Pay averages 20 to 25s a month in the better class companies, some of the smaller ones not giving any salary, but allowing the surgeon to charge passengers for attendance. In most he must supply a complete outfit of uniform, etc., and in some he has also to supply instruments. The duties are in almost all cases gratuitous, all passengers and members of the crew who may require his services, and generally to supervise the sanitary condition of the ship. He is subordinate only to the captain. He must not expect a berth without waiting some months.

NOTES, LETTERS, Etc.

THESAUER TROVE.

THE custom of placing paper money between the leaves of a book for safety, particularly in books which are not likely to attract much attention, and forgetting all about it, was exemplified not long ago when a Turin physician came upon a treasure of silver. The physician had to refer to a book upon anatomy which was in a bookcase in a library belonging to the family of Dr. Giordano, who had been dead some two years. This wonderful book contained some Italian recipes and a receipt for a deposit at the Banca d'Italia, altogether of the value of the above-named sum. The papers were of course handed over to the family of the late doctor.

MEDICAL REGISTRATION.

M.D. writes: Your notice under this heading is a timely one, and may save much annoyance. Several years ago I moved into another street a few hundred yards distant from my former residence, and not being aware of the remarkable habit of the General Medical Council, had not intimated my change of residence. I have reason to believe that all my letters were forwarded, but I never received a line from the Council, and was therefore much surprised to find that my name did not appear in the Register. To me this was of no moment, but to many it might have been of serious importance. Is it not strange, Sir, that this communication, if sent—which in my own case I do not believe it was—should not have been registered?

WATERBORNE CHOLERA.

BRIGADE-SURGEON E. D. TOMLINSON, M.D. (retired pay), writes: In a paper in the October number of the *English Illustrated Magazine*, there is an account of an "interviewing" of Mr. Carl Hagenbeck, who it appears, was the exhibitor of the East African show at the Crystal Palace, and he is also the proprietor of the zoological gardens at Hamburg, and from the account of the interview I take the following extract: "But perhaps the most interesting of Mr. Hagenbeck's many interesting observations on the health of his animals was made apropos of the cholera epidemic at Hamburg. Before the cholera reached the human inhabitants, the inmates of his gardens were attacked by it. They had violent cramps and other choleraic symptoms, and in a short time sixty animals died. He stopped the epidemic, which was clearly choleraic, by boiling all the water given them to drink, a precaution which, if observed by the crowded population near the Hamburg docks, might have prevented the epidemic which attacked them a month later." This statement is interesting as supporting Mr. Ernest Hart's opinion.

MILITARY SANITATION IN INDIA.

A CORRESPONDENT of the *United Service Gazette*, signing himself "Panjab," writes: "I was in Rawal Pindi (Panjab) three or four years ago when General Luck commanded the division for six months. He and Brigade-Surgeon Churchill were most energetic in pushing the pure water supply on; indeed, I believe we were saved that year from an awful epidemic of cholera in the cantonment through their zeal. I do not know how the general squared it with the authorities at Simla, but he was fearless and plucky in everything he undertook. I often heard army doctors say how they liked serving under him." More generals like him would put a very different face on things as they now exist, for it is the want of support by generals that makes the task of the army medical officer in sanitary work so difficult and disheartening.

A CANINE COLLECTOR FOR HOSPITAL FUNDS.

FROM 1660 to 1665 the treasury of the Bristol Royal Infirmary has benefited to the extent of some £33 in all by the sagacious collections of "Punch," a wire-haired brindled Irish terrier. In the course of six years his average annual takings may be reckoned at £5 10s.; the last, that of 1665, consisted of 2,600 coins of all sorts. At the inn called the Plume of Feathers, in Bristol, there is a large tin case on a table in the bar, which is his savings box, and in this he carefully deposits whatever coin may be given him. Above this hangs his portrait. His antics and gambols are amusing enough. He will sit about a spittoon or a heavy chair in the bar and parlour, and make the one or the other gyrate until the clatter attracts attention. Then he looks up, and touches the visitor's pocket with his paw. When given a copper he will jump upon the table, where is placed his savings box, and wait until a bit of biscuit or a cake is brought to him. This he places on his nose, puts the coin in the slit, tosses the cake into his mouth, wags his tail, descends, and proceeds upon a fresh quest. "Punch" is the proud possessor of two silver medals, bestowed upon him by the infirmary, and a handsome inscribed silver collar.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	2s. 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An advertisement of 100 lines or more costs 100 times the above rates.

Advertisements should be addressed, addressed to the Manager, at the Office, not later than upon the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a remittance.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at Post Office addresses addressed either in initials or numbers.

THE HARVEIAN ORATION ON HARVEY AND THE RISE OF PHYSIOLOGY IN ENGLAND.

Delivered before the Royal College of Physicians of London on
October 18th

By W. S. CHURCH, M.D., F.R.C.P.,
Senior Physician to St. Bartholomew's Hospital.

MR. PRESIDENT.—In obeying your request that I should undertake the delivery of the Harveian Oration, I am painfully sensible of the gravity of the task you have imposed on me. For 230 years, with but few intermissions, the College has, in obedience to Harvey's own wishes, assembled to commemorate its benefactors, and if we can no longer precisely follow Harvey's directions, and "commemorate all the benefactors of the said College by name, and what in particular they have done for the benefit of the College," the remainder of his words are still applicable, for part of the Harveian Oration's duty is "to exhort others to imitate those benefactors, and to contribute their endeavours for the advancement of the Society according to the example of those benefactors." This annual office has been filled during the years that have elapsed since Harvey's institution of it by some of the most illustrious Fellows on our roll—by Garth (1697), Arbuthnot (1707), and Akenhead (1750); by Mead (1723), Heberden (1750), and Warren (1768), not to mention others of more recent date, men whose names will ever remain fresh in the history of the literature and medicine of our country. I have no claim to be associated with these great names, nor with the many learned and eloquent men who have addressed you in recent years, and I should have shrunk from attempting the task your favour has imposed on me had I not felt that in asking me to undertake it you were mindful of the position which it is my lot to hold in connection with the great hospital to which the immortal Harvey was thirty-four years physician, in which he exercised an influence over its governing body that remains to this day, and where his memory is yet held in reverential remembrance.

I wish it were possible for me to bring forward from the records of St. Bartholomew's Hospital any new facts illustrating either Harvey's life or works; but many years ago Sir James Paget, in his *Records of Harvey*, exhausted all that is known of him from the journals of our hospital. In the fragmentary notices of him which we there meet with he is seen as the trusted adviser to the governing body, and as the maintainer of the dignity of his order rather than as the physician. In his *Prælectiones Anatomicae Universales* we obtain glimpses of his work in the wards of the hospital, and had his *Medical Observations* come down to us there can be little doubt that in them much would have been found which emanated from the wards of the hospital and the dissections of patients who died whilst under treatment there.

Foremost among the benefactors to our College present to the mind of Harvey when he established this annual Oration must have been Dr. Richard Caldwell and Lord Lumley, who together founded and endowed in 1581 the Surgery Lecture, which, under the name of the Lumsian Lecture, Harvey held from 1615 until 1656, and in the course of which he demonstrated to the College his immortal discovery.

I have failed to find out the nature of the connection, if any, between Caldwell and Lord Lumley. The latter succeeded his father, Lord Arundel, as High Steward of the University of Oxford in the year 1558, the year before Caldwell appears to have completely severed his connection with the university. Of Lord Lumley Camden says "that he was a person of entire virtue, integrity, and innocence, and in his old age a complete pattern of true nobility."

By the kindness of our Registrar, my attention has been drawn to the very interesting notice of Caldwell in Halliwell's *Chronicles*, where an account is given of the first lecture delivered under the terms of this bequest by Dr. Richard Forster, "which was celebrated by a goodly assembly of Doctors, Collegiate and Licentiate, as also

some Masters of Surgery, with other students, some whereof had been Academical. Dr. Caldwell, his white head adding double reverence to his person, notwithstanding his age and impotency, made an Oration in Latin to the auditors, the same by occasion of his manifest debilities unfinished at the direction specialle of the President; who after a few words shortle and sweetle uttered, gave occasion and opportunity to Dr. Forster, then and yet the appointed Lecturer, to deliver his matter."

It is impossible for me to mention the long list of those who, by their munificence or by the honour which their lives and labours have bestowed on the College, have to be commemorated as benefactors since the days of Harvey.

Within the present year we have had a notable example, not only of the generosity, but, what is still more to be desired, of the brotherly feeling which Harvey desired should exist among us. No one among our Fellows has, during the last fifty years, been a brighter ornament to this College or a greater benefactor to his country or the world at large than Edmund Alexander Parkes. It must be a source of gratification to us all that Dr. Hermann Weber, when generously endowing the College with the magnificent sum of £3,000 for the furtherance of original research on the "Prevention and Cure of Tuberculosis" should have associated Dr. Parkes's honoured name with his own. The triennial prize, which the College has decided to found with this bequest, will tend, let us hope, not only to keep fresh in the memories of many generations of Fellows the genial and liberal donor and his valued friend, but may accomplish the object of the giver and lead to future discoveries by which the ravages of tuberculous disease may be controlled and abated, if not altogether prevented.

It may interest the College to know that the subject selected for the first competition is "The Means, Prophylactic or Curative, deemed by the Author to have Value in the Control of Tuberculosis, especial regard being had to their Application to Human Tuberculosis."

I should like to pause here to set before you at somewhat greater length the useful, pure, and unselfish life of Dr. Parkes and to recall to your memory the excellence of his scientific work in connection with the ingestion and elimination of nitrogen in the system, as well as to draw your attention to the benefits which our naval and military services and the general public have received from his labours in the field of hygiene; but I must pass on now and content myself with thus briefly alluding to the munificent gift of Dr. Hermann Weber and the memory of Edmund Alexander Parkes.

Harvey's fame is immortal, and he is to be placed in the same category with Hippocrates, Aristotle, Archimedes, and Newton, who by their genius may be looked upon as not so much the exponents as the founders of their respective branches of knowledge. Aristotle was the first, and in a sense the greatest, of biologists. Harvey was the founder of physiology. Harvey himself was an Aristotelian, educated in all the learning of the schoolmen; and in attempting to estimate his genius and originality it is almost impossible for us in these days of independent thought to realise the crushing influence which authority then exercised on the minds of men; in the words of Dryden, they—

betrayed
Their freeborn reason to the tyranny
And made his torch their universal light.

As in medicine, although there must have been practitioners before the days of Hippocrates, he is to be taken as the starting point, so in biology, notwithstanding the labours of Parmenides, Empedocles, and others of still earlier date whose writings are known to us but by fragments, Aristotle stands alone as the originator of biological science. He, together with his immediate successors, took, as has been observed by Professor Huxley, "the broadest view of the subject, and man assumed his place as neither more nor less scientifically interesting than his fellows."

Harvey's admiration of Aristotle is profound; he calls him the supreme dictator in philosophy, and in the introduction to the *De Generatione Animalium* says: "Foremost among the ancients I follow Aristotle, he is my leader." Dr. W. Ogle,

¹ Dr. Parkes died of an aneurysm of the aorta, March 20th, 1896.

² *Against the Poets. To Dr. Garth.*

³ Appendix to Richard Owen's *Life*.

in the preface to his excellent translation of Aristotle's work *On the Parts of Animals* says most justly: "The biological treatises of Aristotle are more often quoted than read; and it may be added much more often misquoted than correctly quoted." The prominent feature of Aristotle's biological writings, as indeed of his philosophy generally, is classification, in which respect his writings contrast strongly with the poetical and imaginative treatises of his forerunner Plato.

From the time of Aristotle to that of Harvey no advance was made in physiological knowledge; in truth it had receded, overwhelmed by the glosses and erroneous interpretations so often put on Aristotle's writings.

In attempting to estimate Harvey's merits as a discoverer it is necessary for us as far as possible to realise the state of knowledge at the commencement of the seventeenth century, and the nature of his surroundings. Subsequently to the time of Aristotle, who was very imperfectly acquainted, as he himself admits, with human anatomy, the Alexandrian school, where the two rivals, Erasistratus and Hierophilus, practised human dissection, and had considerably advanced human anatomy; their observations and discoveries were made use of by Galen, who added to anatomical knowledge by his accurate dissections of the lower animals, including apes. The anatomical facts thus observed were of comparatively little use through their being treated as disjointed observations; thus there can be no doubt that Erasistratus observed the lacteals in the mesentery of sucking kids hundreds of years before Aselli rediscovered them in dogs; and Aselli's observations would have proved as barren as Erasistratus's had Pecquet not traced the lacteals to the receptaculum chyli and thoracic duct, which vessel had many years before been noticed by Eustachius in the thorax of the horse, and described by him as the *vena alba thoracis*.

With the revival of learning human anatomy began to be studied on account of its obvious bearing on medicine and surgery, and by Harvey's time, owing to the labours of Mundinus, Sylvius, Eustachius, Vesalius, Fallopius, and others, the details of the bodily structure of man observable by the unassisted eye were for the most part discovered.

In physiology, on the other hand, there had been no advance whatever, unless the very imperfect knowledge of the lesser circulation be considered as having a claim to be so regarded. It in no way detracts from Harvey's merit or originality that Servetus, Columbus, and Cesalpinus all had an idea of the lesser circulation, without however comprehending it or seeing to what it led, nor that Fabricius had demonstrated beyond doubt the existence of the valves in the veins. Dugald Stewart has remarked, "in the sciences, the observations and conjectures of obscure individuals on the subjects which are level to their capacities, and which fall under their own immediate notice accumulate for a course of years, till at last some philosopher arises who combines these scattered materials, and exhibits in his system not merely the force of a single man, but the intellectual power of the age in which he lives."⁴

Regard must also be paid to the spirit of the times, and the remarkable uprising of independent thought and inquiry which characterises the century immediately preceding Harvey's birth.

Bacon is frequently spoken of as the founder of inductive philosophy and the destroyer of the syllogistic reasoning which had been all powerful before his day. This may be true when applied to moral philosophy, but is certainly not so when we consider physical or natural philosophy. In his biological writings Aristotle makes constant use of the inductive process, and he points out that it is absurd to suppose that syllogistic reasoning could lead to the discovery of any new principles;⁵ and again he says still more definitely "that reasoning is naturally prior and more known than proceeds by syllogism, yet is that more perspicuous to us which is based on induction."⁶

Aristotle's inveterate custom of specifying a final cause for every structure and organ which he came across in the animal body not only led him into many absurdly erroneous conclusions, but joined with the oft-quoted maxim of Bacon,

"Causarum finalium inquisitio sterilis est et tuncquam virgo Deo consecrata nihil parit," has led to the wonderful work he did in biology being less thoroughly appreciated by us than it deserves. Bacon's objection to the consideration of final causes in physics was owing to his belief that it "banished the study of physical causes; the fancy amusing itself with illusory explanations derived from the former." That Bacon was wrong in this view is proved by Harvey himself, for we have it in his own words, as reported by Boyle,⁷ that it was from studying the valves of the veins, and believing "that so provident a cause as Nature had not placed so many valves without design," that he was first induced to think of a circulation of the blood.

Equally false is the belief very generally held that Bacon was the first to revolt from the tyranny of the Aristotelian school. The alliance which had taken place between the Papal Church and the Aristotelians caused those who at the Reformation refused to recognise the infallibility of the Church of Rome also to throw off their allegiance to the tenets of the schools. Luther and Calvin, not to mention lesser men, declared that no man could be an Aristotelian and a Christian; and St. Paul's warning, "Beware lest any man spoil you through philosophy and vain deceit after the tradition of men,"⁸ was a favourite text for the ministers of the Reformation to expound.

The same spirit of inquiry which broke down the tyranny of the Church also freed men's minds from the trammels of the dogmas of the current philosophy. The physicists, by questioning the accepted doctrines of the nature of the universe, were the first to commence this healthy movement, and the widespread popularity of Ramus's teaching very greatly expedited the change which occurred. Ramus, from the commencement of his career, disputed the authority of Aristotle, and may be said to have spent his whole life in opposing the orthodox philosophy of the times, and perished a martyr to his opinions and the rancour of his opponents in the massacre of St. Bartholomew's Day (1572).

Harvey, when at Padua, must have been in the midst of the conflicting theories and bitter controversies of the Aristotelians and their opponents. His even and well-balanced mind prevented his joining either party. Throughout all his writings he pays the greatest respect to Aristotle, and takes him as his main guide in his work *De Generatione Animalium*. He makes also constant references to him in his *Prolectiones Anat. Univ.*; and when Aubrey asked him what he should read, bid him go to the fountain head and read Aristotle, Cicero, and Avicenna. The same authority tells us that Harvey, whilst esteeming Bacon much for his wit and style, was not enamoured of his philosophy. It would be interesting to know how intimate Harvey was with the Lord Chancellor, and whether their communications merely partook of the character of physician and patient, or whether Harvey discussed philosophical questions with the older man.

My predecessors in this office have so fully vindicated Harvey's claim to the discovery of the circulation against the attempts which have been made within recent years to deprive our countrymen of this honour that I will pass on, merely thanking Sir Edward Sieveking and Sir George Johnson for the able and triumphant manner in which they have refuted the statements put forward in favour of Cesalpinus as the true discoverer of the circulation of the blood.

Neither Servetus, Columbus, nor Cesalpinus in any way anticipated Harvey, who not only discovered the greater circulation, but demonstrated it and explained the true motion of the heart. He, and he alone, recognised the muscularity of the heart's wall and perceived and demonstrated that it was the contractile power of the heart which was the primary cause of the pulse and of the circulation of the blood through both systemic and pulmonary vessels. Harvey by a chain of close and acute reasoning, drawn from direct experiments, and from observations on the pulsation in aneurysms and in vessels distal to aneurysmal dilatations and to portions of rigid and calcified arteries, demonstrated once for all that the motion and contraction of the heart was the main, though not the only, cause of the pulse.

Leaving then the *Exercitatio Anatomica de Motu Cordis et*

⁸ *1 Cor. x. 5.*

Sanguis, I wish to consider that which Harvey's discovery rendered possible, the rise of physiology, more especially in England, and the part which Harvey himself took in founding it.

It must be always borne in mind that but a portion of Harvey's work has come down to us. We gather from his extant writings that he had collected materials for, if not composed and completed, the following treatises: *Observationes de Uteri Lienis*; *Observationes de Motu Locali*; *Tractatus Physiologicus de Amore Libidine et Coitu Animalium*. We do not know how far advanced his *Medical Observations*, to which he makes frequent references: his disquisitions on the *Cause, Uses, and Organs of Respiration*; his *Medical Anatomy, or Anatomy in its Application to Medicine* may have been. Harvey announces, in his first disquisition to Riolanus, his "intention of putting to press this last work," and it must be regarded as an irreparable loss that the world should have been deprived of the material he had collected, for one cannot doubt that his *Medical Anatomy* would have displayed the same master mind as is shown in his other works, and that morbid anatomy would have been advanced to the position it was placed in a hundred years later by Morgagni. As it is we have to collect Harvey's general views of physiology from scattered passages in his works.

Next to his *Exercitatio Anatomica de Motu Cordis et Sanguinis*, his most important treatise is *De Generatione Animalium*. This is an unfinished work. Harvey had probably intended to publish a larger and more complete work, but had failed to satisfy himself on the subject of generation, and what he was persuaded by Sir G. Ent to entrust to him for publication were but the exercises from which Harvey had intended to compile his treatise. Possibly the loss of his *Observations on the Generation of Insects* prevented his undertaking the larger work; for no one who reads the treatise will come to the opinion that Harvey was prepared to publish it in the shape in which we now have it. In the exercises we find much repetition both of words and ideas, much speculative matter on which he expresses no opinion. Not having satisfied himself as to the facts of generation, he allows himself to be under the influence of the

Master Sage of those who know,
(Dante's *Inferno*, Cant. iv, l. 131.)

and wanders off from observed facts into the shadowy but enticing realms of fancy and metaphysics.

It is no detractor from Harvey's merit that he failed in understanding the nature of generation. The necessary means were not in existence; the simple magnifying glasses he used for the inspection of the *punctum saliens* were unable to show him his error in supposing that the male element did not enter the uterus—a conclusion he came to after repeated inspections. Writing of the uterus of the dog after copulation, he says: "I began to doubt, to ask myself whether the semen of the male could by any possibility make its way by attraction or injection to the seat of conception; and repeated examination led me to the conclusion that none of the semen reached this seat." (Exercise lxvii); and in another place (Exercise l) he asks "whether the conception of the uterus be of the same nature or not with the conceptions of the brain, and fecundity be acquired in the same way as knowledge—a conclusion in favour of which there is no lack of argument;" and in his essay on Conception he gives us what I imagine was his final conclusion: "The woman, after contact with the spermatic fluid *in coitu*, seems to receive an influence and become fecundated without the co-operation of any sensible corporeal agent, in the same way as iron touched by the magnet is endowed with its powers."

The aphorism *Omne vivum ex ovo* is ascribed to Harvey, and often quoted as if he made use of the expression. It is true that at the end of his consideration of the development of the egg he concludes by quoting Aristotle with approval: "All living creatures, whether they swim, walk, or fly, and whether they come into the world in the form of an animal or of an egg are engendered in the same manner." But it is quite evident from many passages in his treatise that Harvey did not unconditionally reject the doctrine of spontaneous generation. In Exercise lxxi, after stating "now we at the very outset of our observations asserted that all animals were

in some sort produced from eggs," he goes on to explain his meaning more fully: "an egg is a conception exposed beyond the body of the parent whence the embryo is produced. Let us therefore say that that which is called *primordium* among things arising spontaneously, and seed among plants, is an egg among oviparous animals; the prime conception in viviparous animals is of the same precise nature;" and earlier in Exercise xlv, when discussing the difference between epigenesis and metamorphosis, he says: "Some animals are born of their own accord, concocted out of matter spontaneously." Harvey showed that the mode of development and growth was the same in the embryos of viviparous and oviparous animals, and maintained that in creatures said to arise spontaneously or to take their origin from putrefaction, filth, etc., the same developmental changes occurred, but nowhere expresses an opinion as to the origin of the ova themselves, although it is probable that he inclined to the belief that they were "propagated from elements and seeds so small as to be inconspicuous (like atoms flying in the air) scattered or dispersed here and there by the winds" (Exercise xliii). In the same way he expresses no opinion as to the origin of the animalcules generated in our bodies, and of the worms produced from plants and their fruit or from gall nuts, the dog rose and various other galls, contenting himself with remarking that the living principle of the animals thus arising cannot have existed in the plants on whose juices they live (Exercise xxvii).

Though misled from the want of proper means for observation in the fundamental facts of generation, there is much touching general physiology scattered through the treatise, which is extremely interesting. Harvey remarks that he was the first to note that the bronchia or ends of the trachea in birds open into air-sacs in the abdominal cavity (Exercise iii), an observation which, so far as I know, attracted no attention, and did not receive confirmation until John Hunter demonstrated these air-sacs afresh, and showed that the bronchia in birds were continuous also with the hollow spaces in their bones. In Exercise lvi he has anticipated Darwin's explanation of sexual adornments, remarking, "Ornament, of all kinds, such as tufts, crests, combs, wattles, brilliant plumage and the like, of which some vain creatures seem not a little proud, are most conspicuous in the male at that epoch when the females come into season, and whilst in the young they are still absent in the aged they also fail as being no longer wanted." Hereditary likeness did not escape him, nor that form which is spoken of as atavism, for he asks, "Why the offspring should at one time bear a stronger resemblance to the father at another to the mother and at a third to progenitors, both maternal and paternal, further removed." (Exercise lxxi.)

After the circulation of the blood and the mysteries of generation, the subject which appears to have had most attraction for Harvey was that of "innate heat"—*calidum innatum*—the *Opus Supplicis* of Arcturus, a term by which more was meant than the temperature, although that was the sensible evidence of it. Harvey distinguished the *anima*—soul or vital principle—from the innate heat; to the consideration of the latter he devotes Exercise lxxi, and treats at length of the former in Exercises xxvi and xxvii. It would take me too long to attempt to give a sketch of his views of the *anima*; it is clear that he himself was dissatisfied with his own conception of the vital principle or *anima*, for he says in Exercise xxviii, speaking of the way in which the egg is produced, "leaving points which are doubtful and disquisitions bearing upon the general question (that is, on the *anima*), we now approach more definite and obvious matters."

Animal heat before the knowledge of the production of heat by chemical union was an inscrutable mystery which not even the genius of Harvey could penetrate. The maintenance of animal heat was supposed to be the gift of the heart to the blood. The belief that the heart was the source of heat was universally held by the ancients, Aristotle saying "that its wall is thick that it may serve to protect the source of heat."

This Aristotelian doctrine Harvey dissented from and destroyed by reasoning little less cogent than that by which he demonstrated the circulation, although he was unable to account for the presence of animal heat and imagined that

It was inherent in the nature of blood, and of divine origin. His words are so grand and poetic that I may be permitted to quote them at length:

"I say that innate heat and the blood are not fire, neither do they derive their origin from fire. They rather share the nature of some other, and that a more divine body and substance. They act by no faculty or property of the elements; but as there is something inherent in the semen which makes it prolific, and as in producing an animal it surpasses the powers of the elements—as it is a spirit, namely, and the inherent nature of that spirit corresponds to the essence of the stars—so there is a spirit of certain force inherent in the blood acting superiorly to the powers of the elements, very conspicuously displayed in the nutrition and preservation of the several parts of the animal body; and the nature, yea, the soul in the spirit and blood, is identical with the essence of the stars" (Exercise lxxi). This outburst of Harvey's is most striking, so unlike his usual manner, and one cannot but be astonished at his inconsistency, for it occurs in the same exercise as the following shrewd and calm remark: "We are too much in the habit, neglecting things, of worshipping names. The word blood signifying a substance which we have before our eyes and can touch, has nothing of grandiloquence about it, but before such titles as spirit and *calidum innatum*, or innate heat, we stand agape," for assuredly the substitution of the phrase that the nature inherent in the blood was responsive to the essence of the stars is not less calculated to set us wondering than is the term "*calidum innatum*." Harvey nevertheless disproved for once and all the doctrine that the heart was the source of heat; he showed how animal heat was dependent on the due circulation of the blood and that the belief that the function of the lungs was to cool the heated blood was absurd. He says: "The blood, instead of receiving, rather gives heat to the heart, as it does to all parts of the body; and it is on this account that the heart is furnished with coronary arteries and veins; it is for the same reason that other parts have vessels, namely, to secure the access of warmth for their due conservation and stimulation, so that the warmer any part is the greater its supply of blood, or otherwise, where the blood is in the largest quantity there also is the heat the highest."

The *Praelectiones* are but notes to assist Harvey whilst lecturing, and it is therefore impossible to know what interpretation to place on them, but I think it highly probable that in the course of years Harvey, as his physiological knowledge increased, modified his views of the connection between animal heat and the heart, for in the *Praelectiones* he speaks of the heart as the *fons totius caloris*, and calls it *ars et domicilium caloris*, from which it appears that in 1616 he still held the Aristotelian opinion of the heart being the source of heat.

No portion of the *Praelectiones* show more strikingly the closeness of Harvey's observation, the amount of his knowledge, and the acumen of his reasoning than that relating to the exposition of the anatomy and the functions of the lungs. In his description of them and the pleurae he makes constant references to their morbid anatomy and their embryonic condition. He is evidently in doubt whether the lungs expand and contract from their own movements or merely follow the movements of the thorax—a question which was afterwards fully investigated and explained by Mayow.

The immediate followers of Harvey naturally turned their attention to the subjects on which he had thrown so much light—the circulation and respiration. Most notable among them were two distinguished Cornishmen, Richard Lower and John Mayow. The former is the best known from his experiments on the transfusion of blood, which attracted the attention of the general public, but those experiments, though the best known, are by no means the most important of his physiological researches. In addition to demonstrating in many ways that the red colour of arterial blood was due to the action of the air, he calculated also the force of the heart and the quantity of the blood passing through it. He showed also by demonstrations on dogs that oedema of the parts distal to the heart followed ligature of the veins, and produced ascites by tying the vena cava in the thorax. Lower also was the first to show the dependence of the heart's action on nervous influence and to demonstrate the moderating effect of the pneumogastric nerve on the heart.

Mayow, though recognising that there was an interchange between the blood and air in the lungs, still thought that the source of vital heat was in the heart. "not that it contained a biolynchium (that is, a vital torch) flaring within it, but that from its perpetual motion for carrying on the circulation, the nitro-aërial and sulphureous particles in it must be in a state of perpetual effervescence and that necessarily remarkable heat must be excited."¹⁰ Mayow thought that air was impregnated with a certain universal salt, which was of the nature of nitre, and with vital spirit, and with fire; notwithstanding this erroneous view of the nature of air, it is remarkable how closely his explanation of the action of this imaginary salt on the blood agrees with the actual action of oxygen, and he sums up his conclusions as to the uses of respiration as follows: "Life consists in the distribution of animal spirits which must be supplied for the pulsation of the heart. In very truth it is highly probable that the aerial salt is necessary for any muscular movement, so that without it no pulsation of the heart is possible."¹¹ In his essay *De Respiratione Fetus in Utero et Ovo* he correctly infers that the blood of the foetus obtained through the umbilical arteries not only nourishment but also aerial salts which obviated the necessity of functional activity in the lungs during intrauterine life, and states definitely that the placenta should not be regarded as an amplified liver, but as a uterine lung. It is not for his chemico-vital theories alone that Mayow deserves to be remembered; he first accurately described the action of the intercostal muscles and diaphragm, and showed that inflation of the lungs depended on atmospheric pressure.

It was not until upwards of a hundred years later, when Black had shown the presence of carbonic acid in expired air, and investigated the phenomena of latent and sensible heat, when Priestley had isolated oxygen, and Cavendish and Lavoisier had completed the analysis of atmospheric air, that any real progress could be made in the study of respiration and animal or vital heat. Even now we are by no means fully acquainted with this most complex and difficult subject. Your Croonian Lecturer pointed out a few months ago some of the many difficulties which still have to be surmounted before we can arrive at an adequate knowledge of how and where the interchange between the oxygen of the air and the tissues takes place, and how our systems accommodate themselves to the changes of pressure and temperature in the air, so as to maintain the animal heat at a uniform level.

I have endeavoured, very imperfectly I fear, to set before you the rise of physiology in England. Before the discovery of the circulation of the blood, a right understanding of the means by which life is carried on was impossible, and Harvey's discovery should rank on the same level as Newton's discovery of gravitation. In both cases others had to a certain extent prepared the way, and may have had glimpses of the truth, but to them the truth was revealed, and they might say with Tennyson's Holy Sage—

Idle gleams to thee are light to me,
and the light which their genius led them to perceive enabled their successors to reveal what we now know of the mysteries of animate and inanimate Nature.

We know very little of Harvey's practice as a physician; what little we can gather from his writings show him to have been fertile in resource and skilful in the management of gynaecological cases. We cannot doubt that one who showed such acumen in deciphering the problems of life, and who speaks so wisely of the necessity for the study of morbid anatomy, must have been far ahead of the rest of his contemporaries in the application of his knowledge to clinical work; and the disparaging gossip of Aubrey merely reflects the opinions of those too ignorant and too bigoted to appreciate him.

I have already spoken of the overpowering authority of Aristotle over the minds of the students of Nature, but the completeness of his dominion was not to be compared to the overwhelming influence of Galen in the medical world during the sixteenth and early part of the seventeenth centuries, and it needed yet another than Harvey to enable men to throw off the benumbing mantle of Galen. Our College annals

¹⁰ *De Spiritibus Animalibus*, chap. iv, p. 31.

¹¹ *De Respiratione*.

recount, as pointed out by our learned Librarian in his Roll of the College, that in the year 1559 Dr. Geynes was refused the Fellowship because he had ventured to doubt the infallibility of Galen; and in our annals it is stated that Dr. Hook was not granted admittance to the examination for the licence because he had the honesty to say that he had not read Galen. The revival of anatomy had by Harvey's time somewhat undermined the authority of Galen, which was still further impaired by Harvey's own discoveries. Nine years after Harvey's death appeared Sydenham's *Methodus Curandi Febres Propriis Observationibus Superstructa*, etc., and the world became aware that one had arisen who brought independent thought, unbiassed by the traditions and views of the various schools of medicine, to bear on the study of diseases.

Our ignorance of the details of Sydenham's life renders it difficult to express an opinion as to the position he occupied in society or among his professional brethren in the year 1686, when the *Methodus* first appeared. He had then been settled in Westminster for ten years, and his intimacy during his Oxford life with Locke, and Boyle (to whom he dedicates the work) makes it probable that from his first arrival in town he must have mixed with those bright and inquiring minds who instituted the Royal Society. Be that as it may, his treatise at once attracted their attention, and in the same year in which it was published we find it reviewed in the *Philosophical Transactions of the Royal Society*, then in the second year of its existence.

I will not stay to consider how great or how small were Sydenham's literary acquisitions, or whether he wrote his works in Latin, or whether they were translated from the vernacular by Dr. Mapletoft and Mr. Havers; the subject is fully treated of by Dr. Latham in his *Life of Sydenham*, and I know of no fresh evidence that has been obtained. Whatever may have been the amount of Sydenham's scholarship, no one who reads his works can fail to see from his frequent allusions to Horace, Lucretius, Seneca, etc., that he was intimately acquainted with the Latin classics, and, like Dr. Latham, I should be sorry to consider that his admiration for Hippocrates—the divine old man—was taken at second-hand. As to the other disputed point, whether Sydenham served as an officer in the Parliamentary army, the question has been set at rest by the discovery in the Record Office of a petition to the Lord Protector signed by Thomas Sydenham and endorsed Captain Sydenham's Petition.¹²

Nurtured during the civil war, the rough and turbulent early life of Sydenham left perhaps its stamp upon his character—a thoroughly upright, honest, God-fearing man, but somewhat intolerant of opposition, and of singular independence of mind. He had not the sweet nature of Harvey, which appears to have enabled that gifted man to have lived in peace with all men; but we must, I think, receive with caution the few contemporary anecdotes which have come down to us concerning him. It is pretty certain that Sydenham thought Sir R. Blackmore a pedant and prig—an opinion shared by many, for, besides Dryden's well-known castigation of Sir Richard Blackmore, we have the following description of him by a contemporary:

By Nature formed, by want a pedant made,
Blackmore at first set up the whipping trade;
Next quack commenced, when fierce with pride he swore
That toothache, gout, and dums should be no more,
In vain his drugs, as well as surgery he piled,
His boys grew blackheads and his patients died.

Col. Coddington.

The oft-quoted story of the advice Sydenham gave him to read *Don Quixote* was probably only passing on that which Locke had given Sydenham, for the former says: "Of all the books of fiction, I know none that equals Cervantes's *History of Don Quixote* in usefulness, pleasantness, and constant decorum."¹³ And it may also have contained a covert allusion to the fictitious character of most medical writings.

Sydenham's independence of mind is the key to his position in medicine. The opening paragraph in the preface to the first edition of the *Methodus Medendi* exhibits to us the serious and lofty view that Sydenham took of the physician's duty, whilst in the greatly-expanded preface to the third

edition he instructs us as to the means by which the science of medicine was to be advanced. It was his determination to study diseases as they presented themselves to him, keeping the peculiar and constant phenomena apart from the accidental and adventitious, and laying aside all hypotheses as to their nature, which enabled Sydenham to draw up those pictures of gout, dropsy, and fever which will remain classical for all time and justly entitle him to be called the modern Hippocrates. From Harvey's physiological teaching, and from clinical observations carried on in the spirit of Sydenham, our present knowledge of disease became possible. Harvey's work and writings had no direct influence on Sydenham; the latter makes no reference anywhere to Harvey, nor does he seem, in his treatise on *Dropsy*, written in 1683, to have seen the bearing which Lower's experiments, made fourteen years previously, of ligature of the veins, had on dropsy. Sydenham considered "weakness of the blood" to be the sole cause of dropsy, and throughout his writings he nowhere alludes to the physiology of the tissues. He quotes Hippocrates with approval, as blaming those who in their exceeding curiosity and officiousness busied themselves in speculations on the human frame, and whilst admitting that more than one valuable medicine had been obtained from the chemists, blames those who thought that medicine could be promoted by the new chemical inventions of his day;¹⁴ and he further on says "the whole philosophy of medicine consists in working out the histories of diseases and applying the remedies which may dispel them; and experience is the sole guide."¹⁵ Yet Sydenham himself had his theories, and, viewed by the light of our present knowledge, very incorrect ones, for without theory, or, in other words, general principles, experience is a blind and useless guide. Rational theories of disease and its treatment can only be founded on physiological knowledge, and until, comparatively speaking, a very few years ago the knowledge of physiology and medicine were inseparably connected, for, with very few exceptions, the former was cultivated by medical practitioners alone, and may, without disrespect, be said to have been parasitic on medicine.

This is no longer the case, for using the term in its widest sense, as embracing the study of life, whether under normal or abnormal conditions, it has become the largest division of the natural sciences, throwing out like a gigantic tree huge branches from its main trunk, which depend more or less for support on chemistry and physics, and embracing within its ample boughs a vast series of subjects with whose rapid growth it is beyond the powers of any man to keep abreast. What is to be the future relation of it to medicine, or rather, I should say, of medicine to physiology? The old position is reversed, and medicine—that is, the study of the manifestations of disease, its origin, course, and the means of alleviating its effects or preventing its occurrence—may be regarded as a branch of physiology, and one not less scientific than the observation of physiological phenomena in the laboratory. The practitioner of medicine turns to the physiologist, the bacteriologist, the chemist, and the physicist for aid in unravelling and explaining the symptoms he observes and has to deal with, and so long as they work together in the spirit which influenced Harvey and Sydenham—the pursuit of truth—the world must be the gainer.

The very brilliancy of recent discoveries and the vast increase in our knowledge may for a time react prejudicially on the art of medicine. Are we not in danger of being carried away by our enthusiasm? And may we not fall into the predicament described many years ago by Buckle, of our facts outrunning our knowledge and encumbering our march? More especially does this difficulty arise in the training of our students. So vast is the range of subjects bearing on medicine, and so important does each appear to those best acquainted with them, that there seems to me danger lest, in endeavouring to secure an acquaintance with them all, we may forget that the future life of the majority of those entering our profession is to be spent in ministering to the victims of accident or disease, and that for the due recognition and treatment of sickness and injury, experience and trained clinical observation is absolutely necessary. No amount of laboratory training will enable a man to recognise the nature and proper mode of

¹² A copy of this petition, together with other remarks, was published by Dr. Geo. in St. James's *Dropsey Hospital*, vol. xix, p. 1.

¹³ Some *Templets concerning Learning and Study*.

¹⁴ On *Dropsy*, par. 23, *Opus. Med. Teor.*

¹⁵ *Op. cit.*, par. 45.

reduction of a dislocation, or know scabies when he sees it, and the words of Sydenham to his dear friend Dr. Mapletoft, "The art of medicine can be properly learned only from experience and exercise," will always hold good.

There is no need to urge on the Fellows of the College another of Harvey's directions to the Orator of the day "to search out the secrets of Nature by way of experiment," for at no period during the existence of our College have they manifested greater activity than at the present.

The great scientist who has recently passed away in the fulness of years and fame opened to us new and most fascinating fields for future research, pregnant, I believe, with an abundant harvest, of which he himself was permitted to see the first fruits. Working out with scientific patience and accuracy the clue afforded by Jenner's discovery of the efficacy of vaccination in small-pox, Pasteur not only threw light on the darkness which surrounded the communicability of specific diseases, but placed in our hands a means to fight them. Pasteur has gone to his rest surrounded with all the honours a grateful nation could pay to his memory, and I know not that I can pay a greater tribute to his genius than by saying that he will worthily be placed in the Temple of Fame by the side of our Harvey, both men honoured alike for the blameless character of their lives and the brilliancy of their discoveries. If we, as a nation, have not been able, through the action of our Legislature, to bear our full share in the furtherance of Pasteur's discoveries, we have at least the satisfaction that Lister was the first to recognise their bearing on morbid processes, and to introduce new principles into surgery, which have added a hundredfold to its powers. The later developments of Pasteur's discoveries in the hands of Koch, Behring, Roux, Klein, and a host of equally earnest inquirers have had in medicine a correspondingly important and beneficial effect on our conceptions of disease and its treatment.

Remarkable as has been the nineteenth century in the development of science and its application to the needs of mankind, in no direction has it been more remarkable than in the progress of medicine. The introduction of anaesthetics marks the middle of the century, and its close will in the future be ever memorable as the era in which we commenced to have a truer and fuller insight into the causation and nature of disease than the world has yet seen. Let us all, then, strive to work after the examples of Sydenham and Harvey in the confident hope that as our knowledge advances we shall obtain greater powers of control over disease in all its forms, and that pain and suffering may be yet further mitigated.

MIDWIVES IN BELGIUM.—The Belgian Gynaecological and Obstetrical Society has recently passed resolutions to the effect that midwives should be placed under the active supervision of a competent authority. It recommends that they should be taught to employ certain specified methods of disinfection and asepsis; to use the thermometer regularly, and summon the doctor when the temperature of the patient remains above 101° F. for more than twenty-four hours; to call in the doctor also as soon as any signs of purulent ophthalmia are noticed in the infant. The strictest precautions are enjoined after attendance on cases of puerperal septicæmia, and it is recommended that any neglect in this respect should be made punishable by law. Any case of puerperal fever must be notified to the proper authority within twenty-four hours.

PRINTING AND MORTALITY.—The Labour Department of the Board of Trade has just completed an inquiry into the relative mortality of a number of group occupations. Their inquiry covers (1) printing and bookbinding, (2) shipbuilding, (3) metal, (4) building, and (5) miscellaneous trades. They find that the following are the rates of mortality per mille of the members of the respective unions in these occupations: Printing, 12.27; metal, 11.87; miscellaneous, 10.15; shipbuilding, 9.37; and building, 7.93. Taking the average age at death, printing again occupies the unenviable position of being worst. These are the actual figures: Printing, 44.5; shipbuilding, 46.6; building, 47.5; miscellaneous, 50; and metal, 50.5.

DR. A. L. F. ROBERTSON-FILLARTON has been appointed Deputy Lieutenant of the county of Eute.

SIXTY-THIRD ANNUAL MEETING

OF THE

BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st, 2nd, 1895.

PROCEEDINGS OF SECTIONS.

THE SECTION OF LARYNGOLOGY.

FELIX SEMON, M.D., President.

THE INFECTIOUS NATURE OF LACUNAR TONSILLITIS.

I.—Professor Dr. E. FRAENKEL,
University of Berlin.

UNDER the title of tonsillitis, or angina lacunaris, or as it was formerly called follicularis, we understand an inflammatory affection of the tonsil which is distinguished by its phenomena and course as a disease *sui generis*. It begins in the majority of cases with a rigor and rapid rise of temperature. Simultaneously or after a short delay the patient experiences a sense of uneasiness in the throat. Swallowing, and particularly swallowing saliva, causes him some pain, though this is usually insignificant, and even when he is not swallowing he feels that the throat is not normal, or rather that some slightly painful change has occurred in it. In some cases these subjective phenomena precede the rigor by a few hours. If the throat is examined at the beginning of the illness the palatine tonsils are seen to be red and swollen. A few hours later whitish elevated spots make their appearance, and these prove on closer inspection to be drops of secretion issuing from the orifices of the lacuna. These may be seized and pulled away, and if this is done they usually become drawn out into threads, which retain an attachment to what is left behind in the lacuna. Fresh secretion is formed and expels what is already present, and in this manner drops of secretion reform at the lacunar orifices. They finally gravitate downwards, and may coalesce with similar drops from neighbouring lacunae. In this way a larger or smaller extent of the surface of the tonsil may be covered with the whitish secretion. The latter is of a dense fluid consistency, and adheres fairly firmly to the underlying parts. It is, however, not a pseudo-membrane, for it may be removed without any injury to the surface on which it lies, and proves on microscopic examination to contain no fibrin. It consists in the main of large numbers of cells (chiefly leucocytes, together with epithelial cells), which exhibit granulation and the other usual indications of impaired nutrition. Besides the cells, micro-organisms (chiefly cocci) are present in crowds; but, as I said before, there is no fibrin.

With the further progress of the disease the redness and swelling of the tonsils increase, but these phenomena as well as the pain in the throat usually keep within moderate bounds; while, on the other hand, the fever advances with rapidity, a temperature of 40° C. and more being reached as early as the first evening of illness. Next morning the fever remits, but again rises in the evening, until during the night of crisis the temperature sinks to normal, with the occurrence of perspiration and urinary sediment. In some cases the fever ceases even within twenty-four hours of onset, in others it lasts three or four days. In all cases, however, it gives us, by the suddenness of its onset and by its termination in crisis, the impression of an infective fever, an impression which is strengthened by the disproportion which exists between the local phenomena and the height of the fever, while it is further supported by the fact that in a fraction of all cases a swelling of the spleen is to be detected.

Owing to the favourable course which the disease usually takes one seldom has an opportunity of meeting with it in the cadaver. The pathological anatomy can nevertheless be studied without difficulty. When the affection occurs in individuals who suffer from hyperplasia of the tonsils—and

they frequently are attacked by it—the performance of the necessary tonsillotomy during the acute stage of the disease is sometimes indicated on mere external grounds. Experience of such cases proves that tonsillotomies performed during angina lacunaris do not differ in their course from the usual operation. Since observing this repeatedly, I have during the last few years removed without delay more frequently than formerly hyperplastic tonsils affected with angina lacunaris, and even those in which there was a merely acute and considerable swelling. In this way I have obtained a sufficiency of material for the study of the pathological anatomy of lacunar tonsillitis.

Microscopic examination of sections of tonsils of this kind shows that the most obvious change present is an increase in the transudation of leucocytes from the follicles. This is in parts so considerable that the swarms of emigrating leucocytes so obscure in places the contour of the follicles, as well as of the epithelium, that in various spots (where one can conclude with certainty, on account of the character of the surroundings, that a follicle border or an epithelial fringe must be present) nothing is to be seen of these structures, but only a broad dense current of leucocytes is observed. Moreover, in the neighbourhood of the follicles transudation of leucocytes takes place from the fringe of adenoid tissue underlying the epithelium. The stream of leucocytes is poured into the lacunae, which becomes completely filled thereby, and finally flows out on to the surface through their orifices.

I do not hesitate to say that I consider that the anatomical changes of lacunar tonsillitis consist essentially in an enormously increased transudation of leucocytes. This cannot be due to the transudation being facilitated. Nothing is to be seen, so far as the epithelium and the follicles are concerned, to justify such a conclusion. We must rather suppose that the influx of leucocytes to the follicles and adenoid tissue of the tonsils is increased, and therefore that angina lacunaris is a genuine inflammation of the parenchyma of the tonsils—a tonsillitis in the true meaning of the term.

The same phenomena occur in the other tonsils of the pharyngeal ring of lymphatics as in the palatine tonsils, though less often. Of these, the pharyngeal tonsil is relatively the most frequently affected, but I have seen angina lacunaris occur in the lingual tonsil. With regard to complications, we must mention that it is not uncommon for the neighbouring lymphatic glands to become acutely swollen secondarily, and these may be tender on pressure. The swelling of these glands sometimes lasts considerably longer than the affection.

Under the heading of sequelae, peritonsillar abscess deserves to take a prominent place. Its onset, which is indicated by severe and more localised pain in the throat, generally occurs during the early days of convalescence. It is also worthy of notice that many patients appear to be more pulled down and weaker after their recovery than the slight character of the local affection and the short duration of the fever would lead one in the abstract to expect.

When we now proceed after this short consideration of the pathology and clinical phenomena of the affection with which we are dealing to investigate its etiology, it becomes necessary for us to limit ourselves to such cases only about which there can be no question that they are really cases of genuine lacunar tonsillitis. We must, therefore, exclude from our etiological investigation all those cases in which pseudo-membrane occurs, or in which the Leichter bacillus is found. I do not in the least mean to deny that even in simple lacunar tonsillitis the inflammation may become so intense that fibrin is secreted and false membrane formed. But if we desire to make a clear distinction between lacunar tonsillitis and diphtheria, we shall do well in our etiological investigation to leave these forms out of consideration, and confine ourselves to typical and perfectly pure cases. For the same reason we must exclude all cases in the secretion of which the Leichter bacillus occurs.

Dr. Macintyre and I have divided our task so that the bacteriology should be dealt with by the former. I need not, therefore, enter upon this point.

In elucidating the etiology within these limitations, I think it best to start from certain observations which we have the opportunity of making more frequently than we like. I refer

to the occurrence of lacunar tonsillitis after intranasal operations. Lacunar tonsillitis so frequently follows operative interference in the nasal cavities—especially when the galvano-cautery is used, but also when cutting instruments, or even caustic applications, are employed—that we cannot but suppose that a causal connection exists between the intranasal interference and the tonsillitis; for the latter occurs in individuals who have never suffered from it previously, and who had kept their rooms since the operation. I have often seen it occur in one and the same person on each occasion that the cautery has been used in the nose. It comes on, as a rule, during the first days after the intranasal interference, and affects either the palatine or pharyngeal tonsils, or both of them at once. I have never been able to detect any difference between the course of the traumatic and the spontaneous varieties of the disease. I have found the same micro-organisms in both, and have observed peritonsillar abscess as a sequela of either.

Granted that we are correct in our observation that a true lacunar tonsillitis may be occasioned by intranasal operative interference, there is, to my mind, no other explanation of the matter than the hypothesis that something is carried by the lymph or blood circulation from the nose to the tonsils, which sets up inflammation in the latter. We must suppose that the injury which damages the protective epithelial lining of the nasal cavities throws open the doors to the exciters of inflammation, and that through this door they obtain access to the tonsils from within by way of the lymphatic vessels.

I think that such an explanation of the tonsillitis is much more probable than the hypothesis that the exciters of inflammation make their way into the tonsil by the same route by which the leucocytes make their way out. In some quarters the emigration of leucocytes is interpreted as identical with that from an open wound, but even if that were correct, the micro-organisms would have to enter against the stream of leucocytes. If one studies the emigration of the leucocytes through the epithelium, with particular attention to that point, one sees that the idea is probable, that an immigration takes place with relative difficulty on the same road as an emigration, but at least with as much difficulty as in all other mucous membranes with intact epithelium; for on the road of emigration the advancing micro-organisms are met by the living leucocytes and the stream of serous fluid directed towards the surface. Circumstances which in both cases are, we take it, unfavourable to micro-organisms. That these micro-organisms, and particularly cocci, are to be found within tonsils affected with lacunar inflammation is proved by the microscopic examination of sections stained by Gram's method, in which one can make out in some places single cocci, in others masses of them, even within the follicles.

I have commenced our etiological consideration with traumatic lacunar tonsillitis because, relatively speaking, it presents the most easily intelligible conditions. In accordance with our method of arriving at conclusions *a posteriori*, we must proceed from better known facts, such as these, and draw wider inferences from them, in order to throw light upon points of greater obscurity. For some years I have advocated the idea that lacunar tonsillitis was an infectious disease. I have arrived at this conclusion because the clinical phenomena correspond in every respect with those of an infectious disease, and because I have observed instances of undoubted transmission. I trust I may suppose that my earlier work on this subject is known and that therefore I may omit to adduce further proofs of these facts, especially as in the meantime similar observations have in very many quarters been recorded in literature.

If, during the discussion, any doubt is thrown upon the capability of lacunar tonsillitis being transmitted from man to man, I will adduce proofs in full in my concluding remarks. I take it, however, that no voice will be raised against the transmissibility of lacunar angina.

It might appear that traumatic angina supplied evidence directly counter to the infectious nature of angina lacunaris. If lacunar tonsillitis can occur as a consequence of an intranasal operation, why need we assume an infection at all, in order to explain its origin? This objection, however, only holds on superficial consideration. For we must assume that

an infectious substance exists in traumatic angina also, which travels from the nose to the tonsils, and there sets up inflammation. Also traumatic angina runs the same course as an infectious disease. The injury we must suppose merely serves to open to the inducers of infection a door which was previously closed. Only a minority of the pathogenic micro-organisms known to us are capable of attacking a perfectly normal body or a perfectly normal mucous membrane. In the case of the overwhelming majority of them, an accessory factor must be present to damage and weaken the organism before they can affect it pathogenically. This factor is, in the case of traumatic angina, the intranasal operation. The question here arises as to whether the micro-organisms which cause lacunar tonsillitis must necessarily be introduced into our bodies from without, or whether they are already present in them, but must await an injury to the mucous membrane in order to become pathogenic. Our bacteriological knowledge does not at present enable us to answer the question. Dr. Macintyre will, I suppose, go further into it.

A similar rôle to that taken by intranasal operation in the causation of lacunar tonsillitis is, I think, played by chill. This cause of illness is generally accepted; the frequency, however, of its supposed causal influence stands in inverse ratio to our actual experience of the matter. But I will not deny that sudden cooling of our heated skin, or of portions of it, is capable under some circumstances of causing lacunar tonsillitis, for the simple reason that I have frequently experienced it in my own person. I take it that the chill acts causally merely by opening the door to infective agents. Since the time that I studied traumatic angina, I have seen cases in which the tonsillitis was preceded by a slight rhinitis. Possibly here the chill produced catarrh primarily, while the tonsillitis was caused secondarily from the nose through the lymphatic vessels. I mention this as a possibility without wishing to exclude other ways by which the tonsillitis may be occasioned. The circumstance that an individual who has suffered from lacunar tonsillitis once sometimes acquires a predisposition for further attacks of angina can no longer be used as an argument against the view that the tonsillitis is an infectious disease, for we now know that the same thing occurs in the case of several diseases of this character, for instance, in acute articular rheumatism and pneumonia. Lacunar tonsillitis, then, I regard as an infectious disease; for the infection to become active an injury to the organism must be added. The infective agents may reach the parenchyma of the tonsils by way of the lymph stream. I believe that on this hypothesis the clinical and pathological phenomena of the disease under discussion are brought into harmony. It is true that many points still demand further investigation, which will be the more readily accepted the more we learn to think etiological, or what in these days is the same thing, bacteriologically.

II.—JOHN MACINTYRE, M.B., C.M.Glasg.,

Burgeon for Diseases of Throat and Nose, Royal Infirmary, Glasgow;
Lecturer on Diseases of Throat and Nose, Anderson's College,
Glasgow, etc.

My first duty is to thank the Council of this Section for having conferred upon me the honour of opening a discussion upon the infectious nature of lacunar tonsillitis in association with our distinguished colleague Professor Fraenkel.

For some time past this subject has been receiving a great deal of attention, particularly the study of its etiology, and catarrh in the upper respiratory tract generally, but although considerable progress has been made, much yet remains to be done. In a paper read in the Section of Laryngology at the Nottingham meeting of the British Medical Association in 1892 I pointed out the difficulties which arose on account of the different views in the literature and practice; while bacteriology has done much since then, in this as in many other branches of science, the question deserves further attention. That such terms as "angina," "catarrh," "follicular," "croupous," and other forms of tonsillitis have not been found satisfactory is proved by the many attempts now being made to supply a classification based upon recent scientific investigation. I trust I may not be considered hypercritical if I say that even the name

"lacunar" tonsillitis is not unlikely to disappear with increase of knowledge; and, while admitting its usefulness from certain standpoints, in the present state of our knowledge the same remark, with all due respect, may be made of Sokolowski's classification of tonsillitis lacunaris chronica desquamativa, tonsillitis lacunaris chronica desquamativa exacerbata, and tonsillitis lacunaris pseudo-membranacea. In the paper above referred to it was pointed out that such terms as catarrh, inflammation—in fact distinctions based upon clinical evidences—must in all probability ultimately disappear, and the same remark holds good when we appeal to anatomical distinctions. Consequently, although we have changed the word from "follicular" to "lacunar" tonsillitis we have only succeeded in overcoming to a certain extent the difficulties which arise when different affections attack different anatomical structures or tissues whose names give rise to confusion. A specific example, such as diphtheria, will render my meaning clearer to you, because the recent advances in bacteriological science have made it evident that this affection is due to the presence of a specific micro-organism, and so when the etiology of catarrh, lacunar tonsillitis, or other inflammation in this region is better understood we shall in all probability have no difficulty whatever in supplanting all such classifications. I am aware that this has already been attempted, and that we hear of staphylococcal, streptococcal, and pneumococcal sore throat, but to this question I shall return further on.

The question which I wish particularly to place before you is, How far are we entitled to consider the comparatively well-defined group of signs and symptoms usually associated with the name of lacunar tonsillitis as a specific affection? I think at the outset it may be said that the answer to this question, viewed from the standpoint of modern research, points in the direction of a specific and definite cause or causes being at work in its production; that while many inflammations may be found in the same region, simple, traumatic, or due to constitutional affections, that not one, but perhaps different micro-organisms, may be in causal association with it, we may look forward, and possibly in the near future, to classifying the majority of acute inflammations of the tonsils in definite order, just as we have been able to attribute the true diphtheritic exudations to the presence of Klebs-Loeffler bacillus. In other words, that just as we have found it convenient to group and compare constitutional fevers such as typhoid and typhus, so we hope some day to be able to split up the great group of inflammations in the tonsillar region into its component parts, and assign to each a different place under a generic heading or term. In pursuance, therefore, of a study of the nature of infectious lacunar tonsillitis, it may not be out of place to attempt to make a comparison between it and other acute inflammations of the tonsils, of whose microbic origin no reasonable doubt can now be entertained.

Take the case of diphtheria. Here we believe in an organic cause at the seat of infection producing definite local lesions followed by secondary pathogenic phenomena in distant organs of the body; in fact, a disease which in its main features suggests in every way a constitutional fever whose virulence is due to the toxic effects produced by the definite parasitic micro-organism capable of producing the latter. While it has been arranged most courteously by Professor Fraenkel that he should deal more particularly with this part of the subject, I may be pardoned for here pointing out (1) that in lacunar tonsillitis we have as a rule a well-defined group of signs and symptoms occurring in distinct anatomical structures, and ushered in by a series of phenomena in every way suggestive of an invasion evidently following a period of incubation, the result of a definite and specific cause. A consideration of the local phenomena leaves little doubt that the best explanation of their presence is that of some specific organic source or cause. As we watch the course in the tonsils, we have distinct evidence of local irritation. At first it may be focussed at a part, but as it proceeds its course is such as to suggest organic invasion from point to point; it may be central and pass to the periphery, or it may be spread from one side of the fauces to the other, and all these changes are accompanied with an evidence of irritation, in fact, a casting out of what is evidently deleterious material. Moreover, setting aside the diversity of opinions for a

moment, I am inclined to cast in my lot with those who hold both clinically and from bacteriological observation that we are dealing with an affection which is not only auto-infectious, but capable of transmission from one subject to another. (2) That the clinical evidences are not confined to the local symptoms and signs at the seat of infection. I have been able in many instances, both in hospital and private practice, to confirm the clinical observations made by many others, that we sometimes have evidence of secondary infection of the respiratory and gastro-intestinal tract, that secondary mischief may be detected in the glands of the neck and mediastinum, of the presence of albuminuria, alteration in the normal cardiac sounds, enlargement of spleen, skin eruptions, pleurisy, pneumonia, and irritation of such distant organs as the testes and ovaries, all accompanied by distinct alterations in temperature, prostration, and general manifestation of the presence of a severe constitutional fever. I may be here allowed to say that on the question of paralysis as a sequela I have no definite opinion at present to offer. Clearly the simplest assumption is again that of an infectious disease with constitutional toxic effects.

[Dr. MacIntyre here described a number of cases in which from clinical, bacteriological, and post-mortem evidences septic infection was traced from the tonsils to other and distant organs of the body. Photographs of cases where even Peyer's patches were involved were shown.]

Continuing he said: Further the local conditions are frequently not obliterated after an attack of the disease, and recurrent attacks may produce accumulative effects in the region of the crypts. Reasoning thus the natural suggestion is that careful search should be made for any pathogenic organisms to be found before, during, and subsequent to the attack. No sooner have we engaged in this particular series of investigations than we are beset with many difficulties, because the buccal cavity has been proved by the researches of many, particularly by those of Miller, to be one of the richest seats for investigation of the non-pathogenic and pathogenic organisms found in healthy or diseased subjects. In a series of papers which I read at the British Laryngological Association some years ago I dwelt more particularly upon this branch of the subject, and I think the general opinion of bacteriological and clinical observers who have engaged in this study is that no form of pathogenic micro-organisms is to be detected during the acute affection of the tonsils which may not be present in the normal buccal cavity. This, of course, proves nothing by way of etiology, because the same remark applies to many other specific pathogenic organic causes, but it is a fact not to be forgotten. Salford, if I remember rightly, places it as high as 5 per cent. in healthy subjects, but this is not quite my own experience. During the process of the disease it is easy to satisfy oneself that various forms of cocci, streptococci, most particularly staphylococci and more rarely diplococci, are found in great abundance. In the papers above referred to I gave results, and anyone can satisfy himself of the presence of these organisms in the crypts or discharges in a sufficient number of cases of affected individuals to suggest a causal association. Fraenkel, Kopley, Gabbie, Roux, Sedzink, and many others, are agreed upon the presence of organisms corresponding to the structures which we have just indicated. We are indebted to Professor Fraenkel, amongst others, for the demonstration of the presence of the pneumococcus in a certain number of these cases. Without going into a discussion of the similarity in the structure of these and other organisms found in such conditions as erysipelas, not only is the presence of these organisms now regarded as proved both in the discharges and in the tissues themselves, but carefully conducted cultures show microscopic evidence that we are dealing with the organisms such as streptococci, staphylococci, pyogenes albus and aureus. Moreover, by careful cultivations in suitable media we get macroscopic and microscopic appearances which are quite identical with similar organisms found in other parts of the body, and frequently associated with septic infection. But further, we are indebted to our distinguished colleague, Professor Fraenkel, for he has shown by experiments that those organisms found in the tonsils have pathogenic properties. The presence of definite micro-organisms, even pathogenic, although suggestive of a causal origin if found during the course of the disease, is not enough,

and in a critical survey of the position we are entitled to demand the complete carrying out of Koch's postulates before accepting the theory as proved. It is in this direction, therefore, that much work has yet to be done.

Lastly, Sokolowski and others have shown that in the contents of the lacunae of ordinary enlarged tonsils staphylococci, streptococci, and diplococci, with a variety of forms of organisms usually included under the heading of leptothrix, can be demonstrated. Admitting for a moment that the causal association between such pathogenic micro-organisms and the ordinary form of acute tonsillitis has not been proved, even the most sceptical must admit that the statements above made are at least strongly suggestive that such a theory will be one day substantiated.

There are yet many difficulties to explain away, and Miller has shown that some forms of mischief in the teeth are dependent upon organisms which do not associate themselves usually with the formation of pus; further, what are known as non-pathogenic may under certain conditions be pathogenic. Our difficulties in the study of etiology do not end here, however. Granting the bacterial origin of disease, we must never forget that the causation of all affections is, as a rule, complex. Colds, damp, surface chills, and certain diatheses have at least a predisposing effect; and even families often exhibit similar tendencies. We know that certain individuals are more frequently attacked than others, and the same individual will often show different degrees of resistance at different periods of his life quite apart from variations in the standard of normal health. We know that in the very young and in the very old acute inflammatory affections of the tonsils have not the same hold. Again, climate seasons, situation—for we find epidemics recorded—must be taken into consideration. In considering, therefore, the nature of lacunar tonsillitis whatever be our views upon the active cause of the affection, no study of etiology is complete without a consideration of these and many such predisposing conditions; for it must be granted that whether the affection comes by the air, food, or direct contagion, the same individual at different periods of his life, or groups of individuals more or less pre-disposed to the affection, are subject to similar conditions with totally different results.

In submitting this paper for discussion, let me say that whether we consider it from the standpoint of comparison with other acute inflammations in the same region proved beyond doubt to be the result of specific infection, clinically or pathologically or bacteriologically investigated, we have reasonable grounds for assuming that the time is not far distant when we shall prove beyond doubt that lacunar tonsillitis is an acute infectious disorder of the tonsils belonging to the group of specific affections, which was the thesis I had the honour of submitting to you at the beginning of this paper.

The President drew attention to the ever growing importance of the tonsils as the prominent portal of entrance for the most various pathogenic micro-organisms and explained this as being due to the physiological gaps of the covering epithelium, which are large enough to give easy passage to emigrating leucocytes and to immigrating microbes.

Dr. A. HODGKINSON (Manchester) said that whilst numberless cases of lacunar tonsillitis occur which present no indications of infectious characteristics, yet we have abundant evidence of the existence of an infectious form. There are also numerous cases in which the origin can be found in an intranasal operation, probably by lymphatic absorption. With the object of testing the transmissibility, the speaker admitted a number of cases into the hospital under Dr. Edwards for observation, and not one single instance of direct transmission was noted. What is known as a lacunar tonsillitis may include several forms of disease; that the rheumatic diathesis is very inclined to predispose to tonsillitis is undoubted, in which case chill and fatigue are common causes.

Dr. Wm. HILL considered rheumatic lacunar tonsillitis as one of the most interesting varieties of the matter being discussed. When seeking some years ago for the microbial origin of acute rheumatism, one naturally turned to the cases where tonsillitis preceded rheumatic fever, but it was a remarkable fact that no cases of infection by "oculation" or aërial infection could be found. Whilst most cases of acute lacunar

tonsillitis were contagious, he thought that the rheumatic variety was an undoubted exception; this did not necessarily militate against the probability that microbial life processes in the mouth might by autoinfection or by the dissemination of consequent chemical irritants and toxins in the system bring about in one case lesions in the synovial and serous membranes, in others lymphatic gland involvement, of which phlegmon of the throat is an extreme instance, in others intestinal irritation with enlargement of Peyer's patches and nephritis; such cases reminded one of the parallel instance of diphtheria, where a secondary systemic involvement follows a primary tonsillar lesion. Admitting that various buccal cocci are under some conditions benign and at others pathogenic, he thought that the explanation would eventually have to be sought in the study of various chemical products produced in the mouth as the result of microbial life processes.

Mr. LENNOX BROWN agreed with the statement of Professor Fraenkel that lacunar tonsillitis sometimes followed intranasal operations, and drew attention to the fact that it occurred more frequently when the galvano-cautery was used than when the operation was a cutting or sawing one for the removal of a spur, the explanation probably being that for a certain time the filtering functions of the nose were abrogated, and that some at least of the innumerable organisms of an innocent character which are found in the nasal passages were stimulated into virulence. The accident was a comparatively rare one, and was as liable to produce acute median otitis as an acute lacunar tonsillitis. In the latter case the stage of abscess was rarely reached, probably because it was attacked immediately on its occurrence. In regard to the relation between rheumatism and tonsillitis to which the speaker had revived attention some twenty years ago, it was a doubt in his mind whether both were not examples of auto-infection, the tonsillitis sometimes preceding the rheumatism, at others the rheumatism preceding the tonsillitis. No specific organism had been discovered, for in some cases not only diplococci, both free and encapsuled, but streptococci of the short and rigid—that is, of the least virulent—form, staphylococci, and fungi were indifferently found. The speaker did not believe that there was a high degree of infectiousness in these cases from one person to another, and his experience confirmed the observations of Dr. Hodgkinson. When several cases occurred in a district or in the same family, faults in sanitation or similarity in constitution were probably accountable for the attacks.

Dr. SOXOLOWSKI (Warsaw) said the microscopic examination of several pharyngeal tonsils affected with so-called angina follicularis gave the following results. Weigert's method of staining was used. The lacunae were distended and completely filled with a network of fibrin, in which large numbers of lymphoid cells and micro-organisms were found. In nearly all cases were found many small cocci with numerous diplococci, streptococci, and a few bacilli. A few of these were also found in the epithelial cells. In the upper lacunae a very large number of cocci was found, and in the lower ones the number was much smaller. In all cases fibrilles were found, but the connection of these with the tissue was slightly different to that found in malignant or diphtheritic cases. In these cases the fibrin was found in the tissue, and the tissue itself was partly necrotic. In the cases he referred to he only found very few necrotic patches, and these were only in the superficial layers of the tissue. The epithelial cells of the lacunae can be implicated to such an extent that in some parts they were hardly visible. In some cases not only part but the whole of the epithelial layer of the lacunae was so much infiltrated that it was often difficult to tell where the contents of the lacunae and where the tissue began, except where the fibrin network and the micro-organisms were clearly visible. The adenoid tissue itself was normal, with the exception of an increased infiltration; also the follicles. Several kinds of lymphoid cells were also found. The microscopic appearances seemed to prove that the anatomical changes which were met with in angina follicularis were a diphtheritic process, but of a less severe kind than that met with in genuine diphtheria. We did not, however, yet seem to be in the possession of facts which could satisfactorily explain the etiology of this process. A more detailed description was published in *Deut. Arch. für Klin. Medicin*, 1892.

Professor MORITZ SCHMIDT (Frankfort-on-Maine) wished to know how often his colleagues present had met with lacunar tonsillitis after intranasal operations. For his part he did not consider it was 1 per cent. He could not attribute this to his antiseptic precautions, for he did not rely very greatly on them in the nose. Perhaps it was due to the bactericidal properties of the nasal mucus.

Dr. GLEITMANN (New York) merely wished to say he was quite in accord with Professor Fraenkel regarding the infective nature of the disease in question. But he desired to touch on some points of practical interest. The first was relative to tonsillotomy in lacunar tonsillitis as mentioned by Professor Fraenkel. Until now he was afraid to excise acutely inflamed tonsils, and he was glad to hear that the operation had been done with impunity in such cases. He had seen quite a number of cases in which, after excision of simple hypertrophied tonsils, pseudo-membranes had formed, although the instruments were aseptic, and he had used a solution of hydrate of chloral in glycerine as a paint after this operation, with good results. As to the occurrence of tonsillitis after intranasal operations, especially after application of the galvano-cautery, there was still some doubt in his mind as to their origin. It was not due to septic instruments or cautery points, nor to the subsequent swelling and obstruction after intranasal cautery, for it had occurred with perfectly patent nostrils; the effects of the cautery he had restrained by the application of trichloroacetic acid.

Dr. ST. CLAIR THOMSON thought the subject under discussion was the infectious nature of tonsillitis, and not its septic origin, for the latter was not nowadays doubted by any; nor did it deal with the infective nature, for the cases quoted by Dr. Macintyre of pleurisy, nephritis, etc., subsequent to lacunar tonsillitis illustrated this. The proof of infection in the ordinary way from one person to another had not been advanced. He presumed what Dr. William Hill referred to when speaking of the breath was microbial infection by dust from expectoration, etc., for the researches of Strauss, Grancher, and others showed that expired air never contained any germs, even in cases of tuberculosis. With reference to the question of rheumatic infection from the tonsils, the views of Hill had been fully investigated by Bass. Passing on to the question of intranasal operations being a source of infection, he wished to know if the instruments were quite sterile, for the galvano-cautery might be sterile at its point, but most septic at the barrel. He also suggested that the nose becoming blocked the tonsils became infected owing to their exposure to infection, and the mouth was not used to being open. He had seen recurrent attacks of lacunar tonsillitis arrested by removal of nasal obstruction. With regard to the organisms, it had been pointed out at the Royal Medical and Chirurgical Society in a paper by Dr. Semon that they might have pathological identity with bacteriological diversity, so that we must not expect the discovery of a specific organism.

Mr. L. LAWRENCE gave the history of a family of nine, six of whom had lacunar tonsillitis. The family history was a rheumatic one, but the only members who had had acute rheumatism had not had tonsillitis, and one child had chorea. Adenoids were present in at least one member of the family.

Dr. FRAENKEL replied briefly that in his cases of tonsillitis, secondary to nasal operations, there was no suspicion of sepsis.

Dr. MACINTYRE in reply, thanked the members of the Section for the manner in which they had received his paper. He would only say with regard to the remarks of Dr. St. Clair Thomson that he (Dr. Macintyre) thought he made his views sufficiently plain in his paper. He had nowhere made the statement that he expected a specific bacillus for every known affection. What he did maintain, however, was that while we had strong grounds for believing that lacunar tonsillitis and many such acute affections of the throat were due to microbial causes, the requirements of Koch, before accepting anything as definitely proved, had not been demonstrated in any series of experiments of which he (the speaker) knew. Until these were forthcoming he preferred to say that, viewed clinically, pathologically, or from bacteriological investigations, there were strong presumptions that we were dealing with pathogenic organisms in this affection. With

regard to the remarks of Dr. Hull and others about the rheumatic diathesis, he would only say that the presence of such did not exclude the possibility of septic infection. On the contrary, we know in such conditions, say, as influenza, the liability to tuberculous infection subsequently, and therefore while any known diathesis might exist in the patient, it by no means excluded the possibility of septic infection.

THE FUNCTION OF THE LARYNGEAL VENTRICLES AND VENTRICULAR BANDS.

By ALEX. HOLGKINSON, M.D., B.Sc.,

Lecturer on Laryngology at Owens College; Senior Physician, Hospital for Consumption and Diseases of the Throat, Manchester.

Whatever interferes with the free vibration of the vocal cords during phonation tends to impair the voice, whether used in singing or speaking. By far the commonest agent producing such interference with the free vibration of the normal vocal cords is dust, which in the form of fine physical particles is diffused everywhere to a greater or less extent through the air we breathe. Some of such particles may directly settle on the vocal cords, either naturally during inspiration or may be artificially applied for purposes of observation or treatment. By far the larger portion, however, is drawn into the windpipe and larger bronchi, and, taken up by leucocytes, either passes into the bronchial lymphatics or is carried along by the ciliated cells of the respiratory mucous membrane towards the larynx. In the larynx the current of mucus is distinct along its posterior wall, so as to pass between the cords posteriorly, over the interarytenoid fold, into the glottis, and out of the system by way of the alimentary canal. In this way actual contact with the vocal cords is avoided. Such is the normal course taken by dust laden mucus when the inhaled dust is not in extraordinary quantities, and the mucous membrane is in a healthy condition. Under such circumstances the process of excretion is a gradual one and excites no sensation. If, however, the mucous membrane of the air passages is in an inflamed condition, the above normal process is materially modified. Dust gains access as usual to the air passages, but its mode of exit is altered. Owing to the inflamed condition of the mucous membrane, the action of the ciliated epithelial cells is more or less interfered with, the consequence being that, though the dust particles are taken up by the mucous corpuscles as usual, the latter are no longer carried along separately and in a continuous stream, but collect together in larger or smaller groups. When these collections of mucus are sufficiently large to produce irritation, they are expelled by coughing or clearing of the throat. It is thus evident why, of two individuals breathing the same dust-laden atmosphere, one suffering from even slight chronic catarrh and the other free from any affection, the former is constantly expectorating larger or smaller collections of dark mucus, whilst the latter is free from perceptible irritation.

Occupying an intermediate position to the normal isolated dust laden mucous corpuscles which in health are continuously passing through the larynx without exciting our consciousness, and the larger collections of mucus which excite cough, is a third form of excretion, a form to which I more especially desire to direct attention not only because it is immediately connected with the subject of the present communication, but also on account of its great prevalence amongst residents in our large air-polluted manufacturing towns. This intermediate form of excretion consists of collections of mucus into masses, such masses, however, being too small to excite cough or voluntary clearing. The cause, as in the previous case, is usually a catarrhal condition of the air passages, but that less marked but extremely prevalent condition which is scarcely perceptible excepting during an exacerbation. These small pellets of mucus, varying in size from a millet seed to a size imperceptible to unaided vision, are borne along by the sluggish ciliated epithelial cells towards the larynx. Here their course, though chiefly confined to the posterior wall, is not always so limited. Frequently during phonation minute pellets of mucus are carried to the inner surfaces of the vocal cords and upwards through the glottis. Such pellets of mucus, con-

taining carbonaceous and other particles, may commonly be seen passing between the vibrating edges of the cords during phonation whilst the larynx is under examination. Such passage may, if the little masses of mucus are of sufficient size, cause a momentary interference with the sound of the voice, but, if small, they pass over the edge to the upper surface of the cord without producing any perceptible alteration. If finely divided indigo is blown into the larynx and the glottis examined with a magnifying laryngoscope, extremely minute particles may be seen passing from the edges of the cords, and producing little or no change in the tone of the voice.

If now a fine particle of dust or small pellet of mucus on the vibrating vocal cord be kept under observation, its immediate destination is seen to be dependent on the normal or abnormal condition of the cords. If the cords are normal the particle is seen to rapidly move from the free edge of the cord over its upper surface to pass at a diminished rate below the margin of the ventricular band into the laryngeal ventricle. The rapidity with which the particles move from the edge of the cord depends on the amplitude of the vibration of the cord, and therefore diminishes gradually from its centre towards the extremities. For the same reason that the rate of movement of the particle diminishes as it passes from the free edge towards the attracting border of the cord the amplitude diminishes as this point is approached.

If, however, the cords are not in a normal condition, but inflamed and sticky, the particle behaves at first as in the case of the normal cord, and moves rapidly away from its free edge, but its onward motion is arrested before it arrives at the ventricle, and it therefore remains stranded on the surface of the cord. It is now disposed of in one of two ways. Either it is expelled from the larynx by coughing, or it is cleared off the surface of the vocal cord by the ordinary act of swallowing, in the following manner.

During the act of deglutition, the upper aperture of the larynx is tightly closed by the combined sphincter-like action of its surrounding intrinsic muscles. By their action, and more especially that of the upper fibres of the thyro-arytenoid muscles bounding the laryngeal ventricles externally, the ventricular bands are forced together, and their lower borders brought intimately into contact with the upper surfaces of the vocal cords, and at the same time the contents of the ventricles and secretion from the laryngeal pouches is pressed out of these cavities over the surfaces of the vocal cords. (By the combined action, therefore, of the ventricular bands and the fluid from the laryngeal pouches, the removal of matter adherent to the vocal cords is facilitated. In some instances in which dust blown into the cords has been purposely allowed to remain for some little time without swallowing, several acts of swallowing have been required to remove it, even when the cords have obviously been moistened with fluid from the ventricles. This is evidently due to the fact that in such cases the cords are dry and sticky, since it is only noticed when the cords have been catarrhal. If a powder, such as indigo, be blown on the surface of the normal cords, it seems somewhat more irritating than when enclosed in mucous capsules, since if the cords continue to vibrate until it approaches the entrance of the membrane, a free flow of clear fluid may be seen issuing from the orifice, which carries towards the glottis the particles of indigo which, if phonation is continued, are vibrated back again and again by the action of the cord. If now phonation ceases the cord is abducted, the powder and ventricular fluid may be seen to flow over the edge of the cord into the larynx below. In health, therefore, where powder has been directly applied to the cords, no act of deglutition seems necessary to clear them, the fluid simply exuding from the mouth of the ventricle without apparent muscular action. If, however, as invariably happens, the powder has passed through the glottis and appears on the normal cords in small pellets of coloured mucus, it passes into the ventricles during phonation without exciting any apparent flow of ventricular fluid, and the same occurs when the cords, though slightly catarrhal, are not dry or sticky. When the cords are red and swollen, both powder blown on to them and mucus passing over their edges from below the glottis, though moving to a little distance from the free edges during phonation, adhere to the surfaces of the cords with great tenacity.

In both these instances—that is, when the matter has passed into the ventricles and when it is adherent to the cords—its further disposal is brought about by the act of swallowing, as previously described. Having now traced the progress of the inhaled particles from their entry to the windpipe and larger bronchi, partly to the alimentary canal and partly to the surface of the cords, and partly to the interior of the ventricles, and since their location in the alimentary canal, so far as the present article is concerned, may be regarded as their ultimate destination, it remains only to briefly describe the disposal of the mucus and dust after removal from the cords and ventricles by the act of deglutition. By this act, the fluid forced from the laryngeal pouches in its onward passage through the ventricle washes out the contents of the latter cavity over the surface of the cords, carrying with it any adherent mucus, and is forced out of the larynx between the posterior ends of the ventricular bands over the interarytenoid fold into the alimentary canal. And since matter vibrated from the vocal cords into the ventricles accumulates at their anterior extremities, and since the fluid from the laryngeal pouches is poured into the ventricles at their anterior ends, its passage over the whole length of the cords is ensured by its exit posteriorly. Blackish-grey pellets of mucus from the ventricles may commonly be seen adhering loosely to the edge and posterior surface of the interarytenoid fold if the larynx of an individual in whom dusty mucus has previously been seen on the cords is examined immediately after swallowing.

In the preceding remarks I have attempted to show: (1) That in a normal condition of the air passages inhaled particles of dust, etc., are excreted in the interior of mucous corpuscles or leucocytes, and not floating free in the intercellular fluid. (2) That in health such dust-laden cells do not collect together in masses to be excreted at intervals, but remain separate, passing through the larynx in a continuous stream along its posterior wall between the arytenoid bodies over the interarytenoid fold into the alimentary canal. By this course interference with the vocal cords is avoided. (3) That in a catarrhal condition of the air passages the dust-laden mucous corpuscles collect together in larger or smaller masses owing to the impaired function of the ciliated epithelial cells of the mucous membrane. And for the same reason small pellets of mucus stray from the normal track and during phonation may often be seen passing between the edges of the cords to their upper surface; and if the cord is normal or only slightly catarrhal, moving over the surface of the vibrating cord to pass into the laryngeal ventricles. But if the cord also is in a marked catarrhal condition, the particles become stranded on its surface. (4) That inert coloured powder blown on to the normal cords passes during phonation to the base of the cords, and may never enter the ventricle, but directly phonation ceases and the cord is abducted, may be washed over the edge of the cord into the larynx below by a free discharge of fluid from the ventricle. (5) That the movement of particles from the edge of the cord to near the entrance of the ventricles is due to the vibration of the cord, their further movement into and within the ventricle being due to ciliary action. (6) That dust or mucus adhering to the cords or in the laryngeal ventricles is discharged into the alimentary canal during the act of ordinary deglutition as follows: The glottis is tightly closed and the upper portion of the larynx tightly compressed as previously described. By this compression the ventricular bands rub adherent matter from the cords, fluid is forced from the laryngeal pouches through the ventricles, over the cords, and through the upper aperture of the larynx between the arytenoid bodies into the alimentary canal.

From the above facts it is seen that in man, whilst the laryngeal pouches supply their special secretion, the laryngeal ventricles themselves act as receptacles for dust and mucus cleared off the cords by their vibration, which by its accumulation would otherwise interfere with phonation; and that the ventricular bands have a threefold function: they act as the inner boundaries of the laryngeal ventricles; they assist in closing all excepting the posterior extremity of the upper aperture of the larynx during deglutition; and, lastly, they aid in the removal of matter adhering to the vocal cords, both by friction and by their special arrangement, whereby the fluid from the laryngeal pouches

is compelled to pass over the whole length of the cords from front to back in its passage from the larynx to the gullet.

PRACTICAL DEDUCTIONS FROM THE FOREGOING.

It appears to me (a) that the mucous corpuscles or leucocytes exercise a protective function on the organisation by their property of enveloping particles of dust and germs, and so facilitating their removal from the body.

(b) That the passage of mucus from the air passages along the posterior wall of the larynx, in its passage outwards suggests a probable explanation of secondary infection of this part in pulmonary tuberculosis.

(c) The passage of mucus, etc., from the ventricles through, the glottis into the air passages proves that blood, pus, etc., coughed up from these passages may be other than of pulmonary origin.

(d) The clearing of the cords and ventricles by the ordinary acts of deglutition helps to explain the clearing of the voice by eating, drinking, or sucking lozenges, etc.

The PRESIDENT wished to know whether the reflex cough immediately caused by insufflation of powders into the larynx did not materially interfere with the purity of his experiments.

Dr. CATHCART said Dr. Hodgkinson maintained that the ventricular bands were not necessary for controlling the exit of air, as they were too feeble to resist the strain. Cass and Lauder Brunton had proved that those animals who require their thorax filled with air, as a point of resistance for the muscles which move the forearm in the act of striking, have false cords, and agreed with Wyllie that the air is kept in the thorax entirely by closure of the ventricular bands.

Dr. CLAREMONT would like to ask Dr. Hodgkinson if he considered the backward flow of the mucus as a normal or catarrhal process? In his observations on deglutition did he ever actually observe the surface of the ventricular bands during that act? Did he consider that the ventricular bands ever came into contact with the cords during vocalisation?

Professor MORITZ SCHMIDT (Frankfort) also believed the principal function of the laryngeal ventricle was to prevent air escape: the folds were first distended, then pressed together; the greater the pressure of air, the firmer the glottic closure. The muscular fibres in the ventricular bands are unable to withstand a pressure of more than 80 mm. of mercury. Also during the act of swallowing the larynx is closed similarly, the expiration which follows being a sign of intra-tracheal pressure.

Dr. ILLINGWORTH referred to the theories he had advanced on the previous day in this relation. He considered phagocytosis a mischievous doctrine.

Dr. HODGKINSON, in reply, said that he had been surprised at the tolerance shown by the larynx to powders. They are borne well if not unduly large; if they are not, however, a little cocaine removes the difficulty. With reference to Dr. Wyllie's theory, observation had convinced him that the ventricular bands do not and cannot completely close the upper apertures of the larynx enclosed between the arytenoid bodies. Observations led him to believe that closure of the glottis during straining efforts was done by the cords. The reason, he concluded, was that the cords and ventricles were cleared by deglutition efforts, because after this act the cords and bands, previously dust-laden, were free from it, and the powder was seen on the edge and posterior surface of the interarytenoid fold, these parts being previously clear.

SOME CASES OF DISEASE OF THE LARYNX AND BRONCHI TREATED BY INTRA-LARYNGEAL INJECTIONS.

By ADOLPH BRONNER, M.D.,

Surgeon to Bradford Eye and Ear Hospital; Laryngologist to Bradford Infirmary.

In treating diseases of the larynx and bronchi we try, roughly speaking, to do two things: first, to cure the diseased mucous membrane; and, secondly, to relieve the irritation and cough. This can most readily be achieved by the application of local remedies. Of these we have any number, the efficiency of which has been tried on the mucous mem-

brane of other parts of the body. We know that large quantities of nearly any non-irritating and aseptic fluid can be safely injected into the bronchi, and that they are readily absorbed there (Botey, Schmalz, and others). A menthol solution not only relieves the cough, but has also strong deodorizing and antiseptic properties. I generally use a 5 to 20 per cent. solution in paroline. If about 20 per cent. of water or rectified spirits are added, and the injection well shaken before use, it mixes up much more readily with the secretion in the bronchi. When the expectoration is very offensive and copious, I add 10 to 50 per cent. terebene, or 2 per cent. oleum pimentæ (largely used by dentists), or 3 per cent. eucophen. This is one of the few powerful antiseptics which is soluble in oil. I have tried a solution of salol, which, however, sometimes causes nausea and irritation.

In cases where there is not much secretion I add 2 or 3 per cent. of bicarbonate of soda or boric acid, or 3 to 15 per cent. of tincture of iodine. I have had no experience in the injection of terebene in cases of hæmoptysis, as recommended by Campbell. A glass and metal syringe (made by Down) is used which can be thoroughly sterilised, and which is so cheap that a separate syringe can be kept for each patient; it contains about 1 drachm. If necessary, three or five injections can be made at one sitting, for instance, in cases of purulent bronchitis or bronchiectasis. Before injecting I apply a few drops of a 5 per cent. cocaine solution for the first time or two, till the patient has got used to the operation. In some cases (bronchitic asthma) menthol causes great irritation. It is of great importance that the first few injections should cause as little inconvenience as possible, or else the patient will not call again. The patient is told to take a few deep inspirations and then to say "ah." The syringe is then put in position, and as soon as the cords open the end is introduced and the fluid injected. By pointing the end to one side we can to a certain extent inject the fluid into the right or the left bronchus. The various solutions should be kept in thin glass bottles, a separate one for each patient, and thoroughly sterilised. Pasteur's flask, or an ordinary small thin glass bottle, can be used. The majority of cases which I have treated by injections are naturally of laryngeal disease, chiefly tuberculous or atrophic laryngitis. I will record a few typical cases as briefly as possible.

I.—CASES OF LARYNGO-TRACHEITIS.

CASE I.—Mr. B. saw me in June, 1894. For some years in spring and autumn he has been troubled with a tickling in throat, which generally comes on about midnight, and prevents him from sleeping for some hours. He has tried innumerable remedies, of which only morphine seemed to do any good. There was slight redness and thickening of the vocal cords. I injected at first a 5 to 15 per cent. menthol solution in paroline, and after eighteen injections added 3 per cent. eucophen. He called daily for fourteen days, and then twice a week for three weeks. Last autumn he had no attacks, and this year only a few, which ceased after six injections.

CASE II.—Mr. S., aged 40, has for years been troubled off and on with tickling in the throat and coughing as soon as he gets into bed. The attacks lasted from ten minutes up to one hour. Twenty injections in June and July, 1895, cured the affection. He very rarely has any attacks now, and they only last a few minutes. He calls off and on to have an injection. I used 10 to 20 per cent. solution of menthol in paroline, and for the last few times added 2 per cent. bicarbonate of soda.

II.—ATROPHIC LARYNGITIS.

CASE III.—S. L., aged 25, a mill girl, has for the last ten or twelve years been troubled with violent attacks of coughing several times a day, worse at about 5 A.M.; the cough did not cease until a black crust had been expectorated. I saw her first in January 1893. The ordinary remedies, including iodide of potassium, were tried. In March I commenced injection of menthol solution. In April I added 3 to 10 per cent. tincture of iodine. In June the attacks of coughing had greatly diminished in frequency and violence, and only a small piece of tough mucus were coughed up. Since October, 1893, there have been very few attacks. I injected about fifty times. She comes to the infirmary about once a month for an injection.

CASE IV.—Mrs. P., aged 50, has for the last twenty or thirty years been troubled every winter with attacks of coughing and black, more or less sticky, and offensive expectoration, sometimes very profuse. This was a case of bronchitis and laryngitis sicca. In December, 1893, I injected menthol (10 to 20 M) and terebene (30 per cent.) in paroline. In January the expectoration was much less profuse and less offensive. In February menthol, tinctura iodi (5 per cent.) was used. During the whole of winter (1894) there has been very little expectoration.

III.—CHRONIC BRONCHITIS WITH ASTHMA.

CASE V.—Mrs. L., aged 50, has had bronchitis for years, more in the spring and autumn. During the last few years she has had frequent attacks of asthma. I saw her in February, 1894. There was most profuse and offensive expectoration. I injected at first menthol. This, however, caused great irritation, and had to be discontinued. I then used eucophen (3 per cent.), terebene (30 per cent.), and paroline. In a few weeks there was great improvement. As the expectoration was still offensive I added 2 per cent. oleum pimentæ. During last winter the bronchitis has been much better, and the asthma very slight.

IV.—TUBERCULOUS LARYNGITIS.

In these cases of course local (lactic acid, scraping, etc.) and constitutional treatment must not be neglected.

CASE VI.—J. S., aged 45, has had disease of the lungs for some years. For the last six months he has been hoarse, and had difficulty and pain in swallowing. There was extensive tuberculous disease of lungs and of larynx. For the last few months he has also been troubled with a painful cough, which was worse at night. After a few injections (10 to 20 per cent. menthol) he coughed much less, and was able to sleep at night. For some hours after the injection he was able to swallow without much pain. During the six months he was under treatment (September, 1894, to February, 1895) he gained in strength and weight, and the larynx was much less inflamed. This was of course partly due to the fact that he could take more nourishment and sleep better. Lactic acid was applied to the larynx. The patient has been lost sight of.

These few cases (it is needless to record any more) prove that intralaryngeal injections are most beneficial in some diseases of the larynx and bronchi, and that this method of treatment, although not new, deserves to be more widely known and adopted than it is at present the case.

THE OPERATION OF THYROTOMY.

WITH A SHORT ACCOUNT OF THE CASES IN WHICH IT HAS BEEN PERFORMED AT ST. BARTHOLOMEW'S HOSPITAL DURING THE LAST FIFTEEN YEARS.

By F. DE SANTI, F.R.C.S.,

Surgical Registrar, Westminster Hospital; Senior Clinical Assistant, Throat Hospital, Golden Square.

HAVING for some long while past taken a deep interest in the operative surgery of the larynx, I have in connection therewith had occasion to carefully consider the value of the operation of thyrotomy, especially with regard to its efficacy in the treatment of malignant disease. Up till quite recently I had looked upon the operation as one that should be rarely performed, and it was not until I learnt from Mr. Butlin what excellent results he had obtained with it that I began to change my opinion as to its value.

Thanks to the kindness of my old teacher and friend Mr. Butlin, I have been able to have access at my Alma Mater, St. Bartholomew's Hospital, to the notes of all the cases of thyrotomy that have been performed there up to the present time. Moreover, Mr. Butlin has very kindly allowed me to have notes of all the private cases in which he has performed thyrotomy, so that I am able to put before this meeting a very complete series of cases.

In the *Lancet* of December, 1894, there is a most interesting paper by the distinguished President of this Section, Dr. Felix Semon, on the Results of Radical Operation for Malignant Disease of the Larynx from the Experience of Private Practice. Dr. Semon's results have been most encouraging, and his opinion with regard to the value of thyrotomy with

TABLE OF ALL MR. BUTLIN'S CASES OF THYROIDOMY, ILLUSTRATING MR. DE SANTIS' PAPER, TABLE A.—THYROIDOMIES PERFORMED FOR INNOCENT DISEASE.

(Case.)	(Sex.)	(Age.)	(Part of Larynx Affected and Laryngoscopic Appearances.)	(Symptoms.)	(Nature of Growth.)	(Date of Operation.)	(Method of Operation.)	(Parts Removed.)	(Result of Operation.)	(Last Seen or Heard of.)
1	Male	32	Size of a hazel nut; left side below vocal cord; pedunculated	2 years increasing aphonia; slight dyspnoea	? Fibrous (no microscopic examination)	June 10, 1895	Tracheotomy; thyroid divided and growth removed with scissors	Growth was very firm at 1 1/2 in. at tracheotomy. (Endolaryngeal for tracheotomy had been tried before but unsuccessfully.) Patient could not dispense with tube	Uninterrupted recovery; voice returning	Seen 3 or 4 years later; no recurrence; voice good.
2	Male	32	Mucous membrane thickened and inflamed	Croupy cough and dyspnoea for 6 months. Tracheotomy on admission	No growth; chronic laryngitis and dyspnoea	March 7, 1899	Thyroidomy; nothing removed	—	Expiratory	—
3	Same Patient	—	—	Wearing rubber tube; paroxysmal dyspnoea	—	Sept. 15, 1899	Wound in larynx enlarged; the anterior of larynx examined and found lined by granulations. Probe passed from tracheotomy wound through glottis out through mouth; this was followed by copious gush of blood-stained pus. An O'Dwyer's tube was inserted	With intubation tube in easy breathe well through mouth. Sept. 22. Tracheotomy wound healed. Intubation tube removed; urgent dyspnoea followed and tracheotomy was re-performed. The child wore a tube till Jan. 1, 1901. The tube was then discontinued and in Feb., 1901, left of atropine. Portions of the growth had been removed frequently with endolaryngeal forceps	—	Condition in 1901. Voice much improved. Upper opening through trachea quite patent April, 1901. Tracheal fistulae. Patient breathes per os at intervals.
4	Female	25	Small pedunculated growth growing from under right vocal cord	Hearlessness and aphonia 15 months	Papilloma (microscopic)	Aug. 1899	Tracheotomy; Hahn's tube; division of thyroid; growth removed with scissors, and base scraped and touched with cautery	Excellent recovery. Discharged Aug. 23, 1900	—	Quite well and with excellent voice 2 or 3 years later.
5	Male	37	Middle edge of left cord	Loss of voice 6 weeks	Probably leucoma of the cord	Jan. 24, 1901	Thyroidomy	Only the white patch on the cord	Good recovery; a long and regular voice as good as ever	July, 1901.
6	—	41	Vocal cords	Loss of voice for 2 months; dyspnoea on exertion. Tracheotomy had to be performed at once	Papilloma (microscopic)	Aug. 27, 1901	Under chloroform on Aug. 4, two pieces of growth were removed (largest as a pea) with endolaryngeal forceps. Tube out Aug. 10. Aug. 19, dyspnoea at night. Aug. 26, intubated. Aug. 27, thyrotomy	Growth removed, chiefly from right vocal cord; left vocal cord was covered with sessile growths which were scraped with Verne hand spoon	Recovery; voice returned 24, 1901, with a recurrence	Recovery; voice returned 24, 1901, with a recurrence
7	Same Patient	41	Vocal cords covered with papillomata	Four months after thyrotomy; long dyspnoea; tracheotomy had to be performed	—	Oct. 1, 1902	Thyroidomy; tube left in	Growth removed with curette Recovery; could not do without the tracheotomy tube	—	Recovery almost certain
8	—	7	Glottis thickened by a pink warty mass	Dyspnoea; 1 1/2 years ago; laryngoscopy; not able to dispense with tube since	—	Sept. 3, 1901	Thyroid split, thyroid sutured tube taken out, and only old laryngotomy wound left open	Papillomata removed from right and left vocal cords with scissors and sharp spoon	Uninterrupted recovery	Quite well and with perfect voice many months later
9	Male	30	At and below edge of left cord	Dyspnoea, loss of voice	Papilloma	Sept. 10, 1904	Thyroidomy	Only the growth; cautery applied to place	Rapid recovery. Left voice remains hoarse from lax condition of right cord	July, 1905
10	Female	37	Ant. half of right vocal cord and ant. three-fourths of left covered with a growth some of which was removed with endolaryngeal forceps and microscopied	Loss of voice for 14 months	Papilloma (microscopic)	May 14, 1905	Thyroidomy; Hahn's tube; division of growth of the cord; cauterisation of bases	Endolaryngeal operations by Mr. Hutton and two other laryngeal surgeons were followed by extremely rapid and dangerous recurrence	—	No recurrence, Sept., 1905.

TABLE B.—THYROIDOMIES PERFORMED FOR MALIGNANT DISEASE.

(Case.)	(Sex.)	(Age.)	(Part of Larynx Affected and Laryngoscopic Appearances.)	(Symptoms.)	(Nature of Growth.)	(Date of Operation.)	(Method of Operation.)	(Parts Removed.)	(Result of Operation.)	(Last Seen or Heard of.)
11	Male	51	Size of a walnut, concealing the left vocal cord (microscopied)	Soreness of throat; aphonia and increasing dyspnoea	Malignant (no microscopic examination)	Aug. 24, 1906	Hahn's tube	Tumour too extensive of removal	Recovery; voice returned	Disease still progressing

be removed—and an incision is made from the upper border of the thyroid cartilage, accurately in the middle line, down to about 1½ to 2 inches below the cricoid cartilage. The trachea is then exposed and opened and a Hahn's compressed sponge cannula inserted. Great care, as Dr. Semon has pointed out, must be taken to render the sponge thoroughly aseptic before it is used.

An interval of ten to eleven minutes must now be allowed to permit of the expansion of the compressed sponge, the object of which is to occlude the lower air passages and prevent the entry of any blood therein when the larynx is opened. The parts over the thyroid cartilage are then carefully cut through, keeping well to the middle line until the cartilage is properly exposed; all bleeding having been controlled, the thyroid cartilage is divided medially with bone forceps or a small saw, and the two also are firmly held aside with suitable retractors. Should there be an excess of mucus and saliva obscuring the parts in the interior of the larynx, an aseptic sponge with a silk ligature attached to it may be inserted through the wound into the lower part of the pharynx.

The interior of the larynx must now be painted with a 5 per cent. solution of cocaine, the effect of which is to cause contraction of the small vessels and lessening of any hæmorrhage, and also a diminution of the sensibility of the parts—a very important point if the patient is not deeply under the influence of the anæsthetic used.

Two elliptical incisions carried down to the perichondrium and surrounding the diseased tissues are now made, care being taken to go as wide of the disease as possible.

The growth, if not too friable, is now seized with a pair of fine-toothed forceps, and removed with curved sharp-pointed scissors, the mucous membrane lining the inside of the thyroid and included in the incisions being removed as well. The base is then thoroughly scraped with a Volkmann's spoon, and, all hæmorrhage being arrested, the interior of the wound is dusted with iodoform, and the Hahn's cannula removed at once.

Up to 1890 it was Mr. Butlin's practice to leave the sponge cannula in for the first twenty-four or forty-eight hours in case any secondary hæmorrhage occurred, and the interior of the larynx was packed with strips of iodoform gauze; after the Hahn's tube was removed an ordinary T tube was inserted.

There is no doubt that the compressed sponge surrounding Hahn's tube has in some of the cases of thyrotomy where it has been retained from twenty-four to forty-eight hours acted as a source of septic infection, and, as in the practice of both Mr. Butlin and Dr. Semon, it has been removed as soon as the operation has been completed, and with the best of results, so probably a source of infection can in the future be absolutely done away with by following out their plan. Again, the strips of iodoform gauze packed into the larynx in the earlier operations acted as irritants to that organ, becoming soaked in mucus and saliva, and in some cases getting displaced, hanging down in the trachea and acting as foreign bodies.

The Hahn's cannula should, therefore, be removed at once, the interior of the larynx be well dusted with iodoform, and the whole external wound be left open and covered with a piece of iodoform gauze, changed as often as necessary.

In cases of simple tumours such as papillomata, the technique differs somewhat. When the interior of the larynx is exposed, the neoplasms are carefully removed with scissors, and their bases touched with the galvanic-cautery. Great care should be taken to avoid damaging the healthy parts, and scraping should be avoided. The thyroid cartilage is brought together, the greatest pains being taken to secure accurate adaptation of the alæ, which are fixed with silk or silver sutures. The upper part of the wound is sutured and the lower part left open for drainage.

After-treatment.—The greatest importance attaches to this; to the improvements introduced by Mr. Butlin it is hoped that some of the better results may be attributed. The patient must be kept on his side, that side being lowermost which corresponds to the half of the larynx operated on. The head must be low, one pillow only being allowed. This position diminishes the chances of discharges passing down into the bronchi.

Mr. Butlin feeds his patients for the first day or two principally on nutrient enemata. On the day after the operation an attempt may be made to give fluids by the mouth; water is tried first, the patient being made to sit up and lean well forward; if the water gets into the larynx, it at once runs out through the wound; but should it be successfully swallowed, beef-tea, milk, etc., is given. Feeding by nasal or œsophageal tubes is thus avoided.

The wound must be carefully dusted with iodoform daily, and Mr. Butlin has pointed out that during the act of swallowing, the two lips of the wound into the larynx separate sufficiently to permit of the introduction of the nozzle of an insufflator between them. As a rule, there is but little constitutional disturbance, and the wound rapidly heals by granulation.

In conclusion, gentlemen, I think all that is necessary is to give a brief summary of the actual results obtained by the operation. Of the thyrotomies performed for intrinsic malignant disease, amounting to 14 on 13 patients, there was only 1 death from the operation itself. In 3 cases the disease was too extensive for removal; in 5 cases the disease recurred, 1 patient dying three months and 2 two years after the operation. The fourth case is still under observation. One of these patients was subjected to a second operation, which was again followed by recurrence. In 2 cases the patients were quite well more than three years afterwards. In 1 case there was no recurrence whatever, the patient dying more than five years afterwards of internal disease of uncertain origin. In 1 case the patient was quite well a year afterwards (May, 1895). One operation was performed for disease supposed to be malignant; this was in 1893; the patient is quite well at present.

Of the thyrotomies performed for extrinsic malignant disease, amounting to 3 on 2 patients, 1 died as the result of the operation. In the other case recurrence took place, and a second thyrotomy was performed two years subsequent to the first operation. Within a period of another two years a recurrence took place in the glands of the neck, and death followed an attempt to remove the glands.

The thyrotomies performed for innocent tumours—exploratory purposes, that is—give a uniformly good result, there being not a single death, and the operation having completely cured 6 patients out of 8. Of these latter 2, 1 was a papilloma that most probably recurred, the other a case still under observation, where a small papillomatous nodule still remains. In 1 case the voice remains permanently impaired.

A DISCUSSION ON THE INDICATIONS FOR EARLY RADICAL TREATMENT OF MALIGNANT DISEASE OF THE LARYNX.

L.—D. BRAYSON DELAVAN, M.D. New York,

Consulting Laryngologist to the Cancer Hospital, New York; Professor of Laryngology and Rhinology, New York Polytechnic.

WHEN your distinguished countryman Watson first startled the scientific world by successfully removing a larynx, he, as a pioneer, lacked the aid which to-day should be afforded to us by the records of the work accomplished since his time. Unfortunately these records are far from representing the actual number of cases operated upon, and in many instances are too fragmentary and imperfect to be of any real value.

With the accumulation of satisfactory material now at our disposal, however, the time has fairly arrived in which we should learn, if possible, what good has been accomplished, on the one hand, by the radical removal of malignant disease of the larynx; and, on the other, under what conditions and by what means the best results have been attained. That laryngectomy is a resource of unquestionable prospective value has been abundantly suggested by its latest published records, in spite of the evil name which it at one time acquired, and which until very lately it has held.

In dealing with the question under discussion, I have approached them absolutely unbiased by any theory, and with no other motive than an earnest desire to arrive at the truth both by emphasizing the successes thus far gained and by clearly indicating the errors and the deficiencies which must be removed before the matter can be reduced to a

reliable scientific basis. That need of better information exists is unfortunately true, partly on account of the fact that but comparatively few cases have come under the personal observation of any one observer, and partly because some of the unsolved problems to be met are among the most elusive of scientific mysteries.

Reviewing the history of the subject, we are at once confronted with the fact that any operation for the relief of malignant growth of the larynx, to promise the best results, must be performed at the earliest possible period in the history of the disease, and in a patient in whom the conditions favourable to operation are to a reasonable degree present. In view of this it follows that accurate appreciation of the reasons for or against operation in a given case is an all-important factor in its wise and successful management.

Briefly stated, the indications for the early extirpation of laryngeal cancer will depend upon the prompt recognition of danger; the nature, position, and progress of the neoplasm; the personal characteristics of the patient; the special fitness of the surgeon and of his surroundings for the work, and the impossibility of relief by less heroic means.

Undoubtedly one of the most important considerations in connection with a malignant growth will be its histological character. Thus sarcoma shows less tendency to recurrence than does epithelioma, while the possible success to be attained from the employment of serumtherapy in its treatment may some day remove it from the sphere of surgery altogether. Adenoma, although possessed of well-known liability to epitheliomatous degeneration, gives much better results from early operation than does carcinoma. Of the various forms of epithelioma, that which originates as a well-localised, slow growing, papillomatous-like tumour may be extirpated more thoroughly and with less damage to the parts than the variety characterised by diffuse infiltration. Several of the most successful laryngeotomies on record have been done in cases either of doubtful diagnosis or of distinctly not carcinomatous character.

The location of the growth is another element likely to affect the prognosis. It is held by many surgeons that in cases where the disease is extralaryngeal, or where there is glandular involvement, operation is rarely admissible. Occurring within the larynx, its restriction to one side of the organ, to the superficial structures or to a comparatively limited area, must, of course, increase the possibilities of successful operation. Involvement of the œsophagus is one of the most unfavourable complications, on account of the difficulties in the way of recovery and the necessity for permanent artificial feeding.

Again, the activity of growth shown by the neoplasm may afford a slight degree of suggestive evidence as to its future progress, and, although far from being infallible, may foreshadow to some extent the probabilities of tardy or rapid recurrence.

Having arrived, in the study of the nature and situation of a given growth, at conclusions favourable to its radical extirpation, the next question to be settled will be the personal characteristics of the patient himself. Account must be taken of his age, vitality, and general physical condition; of his temperament, his intelligence, and finally of his station and surroundings in life.

Age, absolute or relative, will shorten the natural expectation of life, and thus detract from the value of even a successful operation. It is less desirable to inflict such an ordeal as laryngeotomy upon one whose days are already numbered than upon one to whom a fortunate operation may bring years of usefulness.

Again, upon the assured vitality of the patient will depend not only his immediate recovery, but the success with which he will ultimately rise above the physical depression incident to such a severe surgical measure. It would be instructive to know in how many of the cases which have died without recurrence within a few years after laryngeotomy the fatal issue has been largely due to the general effect upon the system of the operation.

Perfection of the physical condition in general and of certain organs in particular will add greatly to the prospect of success. Thus, on the contrary, certain impaired conditions of the heart or lungs will increase the liability to pneumonia, and almost necessarily fatal complications; bronchial irrita-

tion of any kind, accompanied by cough and expectoration, will seriously affect the patient's comfort, and dangerously interfere with the successful progress of the cervical wound; gastric disturbance must also be taken into account, as will readily be believed by anyone who has seen the effect upon a recently operated case of a single attack of emesis, or of continued indigestion.

There are at least four cases on record in which the subject of a so-called successful laryngeotomy has committed suicide; nor can we wonder that the ordeal of the operation and of the period of convalescence, the physical deformity incident to it, the impairment of the power of speech, the social ostracism of the higher order of man, and the physical incapacity of the lower, should call for rare equanimity and almost superhuman moral courage on the part of the one obliged to face such a situation. The temperament of the patient therefore may easily become the determining factor in the success or failure of the result, while upon this, and upon his surroundings, and the intellectual ability to adapt himself in the most satisfactory manner to the latter, will depend the toleration with which he will meet his life. Both the instinct and training of the surgeon lead him to heroic efforts in the preservation of life. It is a grave question, however, and one not to be lightly dismissed, whether some lives, as influenced by the results of laryngeotomy, have been worth the living after all. Already several patients have taken the matter into their own hands, and have decided in the negative.

Very few men in public life could have shown the fortitude of that celebrated patient of our chairman, whose history subsequent to operation is such a brilliant tribute to the wisdom of the operator and to the moral courage of the man himself. Hickey, on the other hand, a triumph in every way of surgical ingenuity and success, is a helpless inmate of the almshouse. Unquestionably, laryngeotomy should not be performed without a full understanding on the part of the patient of the nature of the operation and of its results.

The indications for the early radical treatment of malignant disease of the larynx, as far as the growth is concerned, are therefore:

1. A growth of undoubted malignancy.
2. Located within the larynx.
3. Favourably situated for complete removal with the minimum of injury to the surrounding parts, and
4. With the best outlook as to the possibility of non-recurrence.

Concerning the patient the indications are:

1. That he should not be too old.
2. That he should be possessed of good vitality.
3. That he should suffer from no physical defect likely to complicate recovery or seriously annoy him afterwards.
4. That he be of a cheerful, courageous temperament.
5. That his intelligence be fair and his surroundings such as to make it possible for him to exist with moderate comfort after operation.

That these specifications should seem exacting is not denied. They are not unreasonable, however, as proved by the general experience of the past.

Undoubtedly, if radical operation is justifiable in these cases, the sooner the growth is removed the better. This being the fact, the early recognition and diagnosis of it is of paramount importance. Indeed, it is the veritable key to the whole situation. Just here, however, we are confronted with a difficulty in many cases hitherto insurmountable. Either the disease has been unrecognised by the general practitioner until the favourable time for operation has passed, or else the difficulties in the way of early diagnosis have been so great that not even the skilled specialist has been able to solve them.

Sarcoma, and even adenoma, may sometimes be diagnosed with comparatively little trouble. The difficulties in the way of the early recognition of epithelioma, however, have formed the basis of historic controversies and of an extensive literature. Summarised, the early diagnostic signs which possess the slightest value are few in number, and often both unreliable in character, and extremely hard of detection. Thus the neoplasm may appear in one of no fewer than three different forms:

1. The distinctly localised and somewhat superficial papillomatous-like excrescence.

2. The deep fairly localised neoplasm with irregular or nodular surface.

3. The variety beginning indefinitely, and extending for some time in the form of a general diffuse infiltration.

In the papillomatous form the growth manifests itself somewhat superficially, and its characteristically tumour-like appearance makes it at once an object conspicuously striking to the eye. But even with this apparently helpful feature, how often has early diagnosis been impossible! Between it and ordinary papilloma in many cases the eye cannot decide. The statement that the appearances at the base of the growth will show marked peculiarities in the experience of the writer has often been disproved. True, the tendency to advance from before backwards in the direction of the larger muscular masses; the occurrence of muscular infiltration, with more or less fixation of the affected side, the presence of lancinating pain, all these may be strongly suggestive to the practised observer of malignant disease. But these signs, unfortunately, have to do with the extension of the disease, not with the localised wart which has been early discovered, and the true nature of which it is of such vital importance to determine. With deepest respect for the microscopist and his work, how often has that trusted resource not only failed to demonstrate the true condition, but by its misleading testimony has caused such delay as to have effectually sealed the fatal verdict.

In the other forms of epithelioma in which the focus of disease appears to be more deeply seated than in the above, the impossibility in many cases of removing a specimen for early examination at once renders the microscope of little or no use.

Transillumination, as suggested by Voltolini, has not proved of practical aid.

Again, as has been shown by the speaker, malignant disease may not only simulate other conditions, and in turn be simulated by them, but it may even coexist with them, so that the demonstration of the tubercle bacillus or the presence of typical specific scars may by no means exclude the diagnosis of cancer.

Failure on the part of the general practitioner to realise the existence of a malignant growth in the larynx until long after the favourable period for operation has passed is a matter of common occurrence. Case after case is presented to the specialist in which the destructive progress of the disease has left no hope for the patient beyond the temporary relief of a tracheotomy. While it may be by no means certain that the result of the case would have been materially different had it originally fallen into other hands, yet it is unquestionably true that in cases possibly amenable to the only known method of relief such delay is fatal.

In view of the inability of the expert in this direction, however, the general practitioner must not be exposed to undue censure. The difficulty lies in the fact that the condition is rare and unfamiliar to him, and that he is, therefore, unable either to recognise or to appreciate it. If it be true that the specialist is in need of more reliable diagnostic signs than he now possesses, it is also the case that the practitioner should have a better knowledge of the means for examining the larynx, and of the recognised symptoms of possible danger. Unless he is to that extent qualified, it is surely wrong that he should undertake the slightest responsibility in so serious a matter when, by referring to the nearest dispenser, the patient could have been warned of his danger. In the case of either practitioner or expert, the present state of our knowledge of the diagnosis of cancer of the larynx is such as to make additional light upon the subject imperatively necessary.

Failing in other diagnostic means, the practical resource at present at our disposal is thyrotomy. Where the diagnosis cannot be promptly made by endolaryngeal methods, it is maintained that the best course is an exploratory thyrotomy, immediate examination of the growth with the freezing microtome, and then partial or complete excision, according to the necessities of the case.

The objections to this are the infliction of a somewhat severe measure upon a possibly benign case and the chance that the testimony of the microscope may prove unreliable

after all. Fortunately, improved methods have made thyrotomy a much less formidable operation than it was formerly considered. But, even so, its employment should be entrusted to conservative hands, and, above all things, operation upon non-malignant cases avoided. Far better that even this should happen, however, than that the unfortunate error of extirpating a larynx unnecessarily should be repeated. There is no question that in most cases thyrotomy will generally be useful in confirming diagnosis already fairly well established in expert hands. To apply it indiscriminately would be highly objectionable.

Clearly, what is needed is some reliable test by which, in spite of uncertain local appearances and in the presence of general complicating conditions, the true nature or tendency of the growth may be established from the earliest possible period; and the chances for successful treatment thereby proportionately increased. Just what this will be it is impossible to say, but as tuberculin has given us a guide to the diagnosis of tuberculosis, may it not be possible that the future may see the development of some analogous method as applied to the demonstration of malignant disease?

Since prompt diagnosis is a matter of such urgent necessity, and at the same time of such acknowledged difficulty, the importance of securing for the patient the best possible advice cannot be too strongly urged.

To summarise again: Granting that radical operation is justifiable, the earlier it is done the better, and to that end it is all-important that there should be a more widespread diagnostic knowledge of the subject, and that the facilities for early diagnosis should be greatly improved.

Before unreservedly advocating capital operation, it would be well to eliminate the possibility of aid by other means, admitting that in the present popularity of the former resource these methods have been allowed to fall into undeserved neglect. Thus, the treatment by local applications of various non-malignant growths of a more or less vascular nature and of small size has often proved useful. In two cases of extensive papilloma lately seen by the writer, a complete cure was effected by repeated local application to the larynx of a spray of alcohol as suggested by Birkett, of Montreal. The persistent use of astringents will visibly retard the progress of certain neoplasms, while, with others, the application of lactic or chromic acid has resulted in marked benefit. Unfortunately, in a genuine case of epithelioma such results are not obtained. If it should be proved by the study of a larger number of cases, however, that the alcohol treatment is curative in ordinary papilloma and without effect in malignant disease, a diagnostic point of some value would have been established.

Endolaryngeal operation, much as it may have fallen into disrepute through the advocacy of other methods, has at least this to be said in its favour, that the patient's life is neither sacrificed by an unsuccessful operation, nor his future made wretched by the results of a successful one. It may be questioned whether certain forms of growth cannot be more safely treated in this way than any other. As to epithelioma, however, the outlook seems absolutely bad, and while cases have been known in which it has succeeded, the testimony of the last few years is against it.

As to constitutional treatment, there is probably not a case on record where a true laryngeal carcinoma has been cured by medicine.

The question of the value of serumtherapy, however hopeful in the case of sarcoma, for carcinoma has thus far been answered in the negative. If the inoculations were of no greater value, however, than to demonstrate, after the manner of tuberculin, the presence of the specific disease, an important diagnostic point would have been gained.

Whatever may have been the case in the past, in the light of our present knowledge the indications are pretty clearly in favour of the operative treatment of epithelioma of the larynx.

OPERATION.

Having studied thus far the indications for the early surgical treatment of malignant disease of the larynx, it next becomes necessary to consider the questions connected with the technical part of the subject—namely, the operations for the removal of the disease and the care of the patient during recovery.

As to the operative procedures in general, it may be said that while they are undoubtedly much better than they were fifteen years ago, the most of them are yet by no means as perfect as is desirable. As far as freedom from hemorrhage and non-interference with respiration during operation are concerned, a high degree of perfection has been reached. Measures for avoiding pneumonia and certain insidious forms of sepsis, especially those affecting the nerve supply of the heart, are still very imperfect and unreliable, and until they are furnished the statistics of operation must continue to be unsatisfactory. Eliminating the above accidents, on the other hand, the operation of laryngectomy would be reduced to what might be called a fair basis of practical usefulness.

In reviewing the literature of laryngectomy several interesting facts present themselves. Apparently it has not always been the best general surgeons who have obtained the most favourable results in this department. On the other hand, some of the most brilliant work on record has been done by men known principally as laryngologists rather than as general operators. Several of these gentlemen, let it be said, have operated in connection with general surgeons of well-known ability. No more favourable combination could possibly be made. Again, many surgeons of high repute as general operators have signally failed. Were the true history of their work to be known, it would often appear that failure has been due to lack of appreciation of the peculiar needs of these cases and of the special skill and knowledge required to manage them. To conduct a laryngectomy as one would manage an amputation is to lose the case. Laryngectomy has sometimes been undertaken by men unskilled in general surgery, without proper aid and in the midst of improper surroundings, with results, of course, of the worst.

Another requisite for the successful management of these cases is an accurate knowledge of the physiology of the throat. This is not only valuable during the time of operation, but absolutely indispensable to the correct understanding of many of the various accidents, direct and reflex, which may occur during early convalescence. To secure the best success, therefore, the operator should first of all be a surgeon thoroughly practised in all that contributes to make a good operator. He should have had special training in the surgery of the neck and in the physiology as well as the anatomy of the laryngeal region. He should be a master of antiseptic methods and of good judgment in the after-care of the case. Finally, he should have at his disposal the resources of a perfectly equipped and thoroughly well managed modern hospital of the best class. As the dangers, not only of operation, but of the first days after operation, are of conceded importance, it is necessary that this part of the case be managed with extreme care. Many a patient has died of preventable accidents whose life would have been spared if he had had the constant care of a highly-skilled watcher. As has been eloquently insisted by Solis Cohen, such a case should never be entrusted to the *interior* nor to the assistant without experience in such matters, but should have within reach an attendant only less competent than the surgeon himself, qualified to appreciate the special necessities of the patient, and to promptly meet any emergency that might arise. Obvious as this suggestion would seem to be, the necessity for dwelling upon it will be apparent when we find in how many cases death has been due to accidents in feeding, to improper care of the wound, etc. It cannot be insisted too urgently that carcinomatous cases requiring laryngectomy are desperate at the best, both as to immediate and as to ultimate results, and that, with our present limited knowledge of the subject, no amount of caution, however great, will avail in preventing a high percentage of failures. With the sources of danger so numerous, so constant, and so subtle, it is impossible that too great vigilance, foresight, or experience be brought to bear against them, or that the urgency of this demand be overstated.

Unfortunately it must be admitted that laryngectomy at present appears to be our only resource, and unsatisfactory as its results may often have been we are obliged, for the want of something better, at least to regard it with respect. It is not only wrong to the patient to diminish by the slightest degree his prospects, but an even greater injustice to the operation itself to so perform it or so to care for the patient afterwards as to throw discredit upon it, thus hin-

dering its progress and depriving other sufferers of its possible benefits. Improved management after operation, as has been said, requires first of all the constant attendance upon the patient of assistants thoroughly qualified by experience, as well as by precept, to skilfully care for the case. It is not by any means enough that the watcher should be ordinarily qualified in the care of severe surgical cases. Nothing short of special fitness in the department of this particular class of cases will yield the best results. Next, it demands that the possibilities of certain accidents be recognised and their causes carefully guarded against. Among these the dangers from the entrance of foreign matters into the air passages, and the mishaps due to carelessness in feeding, are among the most common and dangerous. For the prevention of the latter it would seem that the means at hand, namely, rectal alimentation, the œsophageal tube, and Wolfenden's method, were adequate if properly used. It has undoubtedly been the case that the œsophageal tube, when entrusted to inexperienced hands, has more than once resulted in disaster. This part of the management, as proved by the records of accidents, cannot be too carefully conducted.

Another dangerous and preventable accident is the poisoning of the patient by the antiseptic dressing. Within the personal experience of the writer, this has occurred in no fewer than four cases; while the whole number, recorded and unrecorded, is very considerable, including several which have been attended with a fatal result. As has often been pointed out, the magnitude and the location of the wound render absorption particularly easy. In this class of accidents iodoform has been the principal offender. That it is not the only one is shown, among other examples, by the very interesting case treated by Dr. Roswell Park of New York, who, "remembering the symptoms of iodoform poisoning which had been observed in a former laryngectomy, substituted oxide of zinc gauze instead of iodoform gauze for packing the wound. The patient did well until the second day, when she began to suffer from increasing dyspnea and cyanosis which, in spite of every effort to relieve it, persistently increased, causing death in a few hours. Necropsy showed that the interior of the small bronchial tubes was coated with mucus whitened with the oxide of zinc, and which had been made so tenacious thereby that death seemed to be due to the impossibility of oxidation on account of the obstructing film."

Between the ever-present and persistent danger of sepsis, on the one hand, and the accidents alluded to above the necessity for skilled and experienced care is again strongly emphasised. As the prevention of sepsis will always be one of the most serious considerations in these cases, it is highly desirable that some disinfectant be found which shall combine the best antiseptic with the least toxic properties.

The indications for laryngectomy itself, as far as the technique of the operation is concerned, must depend more or less upon the possibilities present in each given case. Opinions differ as to whether the better results may be obtained by partial or by complete removal of the larynx, and the results of operation certainly tend to leave the question somewhat in doubt. While it would seem *a priori* that the less removed the better, the fact still remains that in some of the most successful cases on record the entire larynx has been extirpated. The arguments for and against the various forms of operation I shall not attempt to discuss.

Referring to the latest successes in this department, we have, on the one hand, the remarkable results of partial removal obtained by Semon; and, on the other, not to mention the successful work of earlier operators, the cases of complete removal done by Solis Cohen, Schmidt, and Swain. The method pursued in the last-named cases, and illustrated in the patient herewith presented, is certainly one which commends itself highly on account of its several decided advantages over the ordinary plan of operation. These advantages, as explained by Swain, have been well shown in the case before you. Briefly stated, they may be described as follows:

1. The danger to life from inspiration pneumonia is greatly lessened owing to the shutting off of the mouth from the trachea.

2. Swallowing is accomplished with great ease and as freely as usual.

3. In at least three cases thus operated upon the power of phonation has been acquired, with a voice fully as satisfactory as that produced by any artificial appliance, and that without either the inconvenience and discomfort of an artificial larynx, or the danger to the adjacent parts from the irritation of its presence.

4. The comfort of the patient is greatly increased, and the disfigurement of the other operation and of the wearing of the artificial larynx largely done away with. It seems entirely probable that this method will prove to be most satisfactory of any yet proposed, and it is to be hoped that it may be given a sufficient trial to prove whether or not these cases have been but the result of a happy accident rather than the first illustrations of a definite rule.

The case of Hickey suggests what must have been true in other instances in which life has been unusually prolonged, namely, that doubt as to the actual fact that carcinoma has originally existed must always be present where its characteristic appearances have not been clearly proved. Heretofore recurrence has been so certain that, without indisputable proof to the contrary, permanent cure has always excited the suspicion that the case must have been other than one of epithelioma. Indeed, even in the best of hands the tendency to recurrence has seemed an impassable barrier to genuine success, and case after case in which the best possible surgical results have been attained has sooner or later succumbed to it. The question of recurrence is by no means as hopeful as is that of successful technique. The latter has evidently accounted for Bull's remarkable series of recoveries. The record of immunity from recurrence given in the lately published statistics of Semon is certainly the most brilliant in the history of this subject, reviving as it does a strong hope for the ultimate success of a class of operations which from past statistics have been in no little danger of falling into disrepute.

Although there may not seem to be many new suggestions in the statements herein made, I have brought them forward for the purpose of placing them prominently before you, and of leading up to the main proposition of the discussion. In making them I have sought to call attention to the importance of bringing to the case the highest diagnostic skill. The necessity in dealing with it for the exercise of peculiar special ability on the one hand, and eminent surgical experience on the other; the urgent importance of surrounding the patient with every possible means of aid, and of eliminating as far as possible every element of danger.

While fully appreciating the good work already done, and recognising the hopeful outlook for the future, I have dwelt with all possible emphasis upon the difficulties, uncertainties, and dangers of the present situation. This I have done for the purpose of insisting upon the urgent gravity of the subject, and of distinctly discouraging the class of effort which has too often been brought to bear upon these cases. Personally I have never performed a laryngectomy, otherwise it would be impossible for me to advance the proposition which I am about to offer. Let me beg you not to misunderstand the spirit in which it is given, and to receive it with the largest possible share of humane impulse and of generous breadth of view.

The situation is one of the most peculiar in the whole realm of our art. We are fairly groping for light upon the subject of one of the darkest and direst of human ills. The matter has reached a point which places it almost beyond the pale of individual ambition, for these patients are usually too poor to appeal to the acquisitive man, and the operation has been so often performed that to lose a patient or two for the sake of having done it has long since ceased to bring anything but discredit. The majority of us can well afford, therefore, to exercise a fair amount of self-denial if by so doing the general good may be promoted. I am strongly of the opinion that for a time both the welfare of patients operated upon as well as the interests of science demand that the indiscriminate performance of capital operations upon the larynx should cease. In most great centres there are individual surgeons or groups of operators who are especially well fitted, both as to personal qualifications and hospital facilities, for the successful performance of this work,

as has been proved in many cases by the records which they have already made. Let such men surround themselves with the proper assistants, let them systematise their efforts, and use all diligence in the perfecting of appliances and methods and in the study of the cases under them. Let them keep careful and accurate record of everything pertaining to the history of their work. Then resign to them temporarily the care of as many cases of laryngeal cancer as possible. When a sufficient amount of material should have been collected let them place the latter upon a substantial scientific basis, or as one advance after another had been made let them give to the profession in general the results. Then we would soon learn whether the radical extirpation of laryngeal epithelioma is on the whole unjustifiable, or whether—as we have the best reasons for hoping—it has already proved a substantial success. Already the example has been set in this place. It would be fortunate indeed if it could be followed, and with as gratifying results, in other parts of the world.

In conclusion, to state the matter broadly, the indications for the early operative treatment of malignant disease of the larynx are the prompt recognition of a neoplasm of a type impossible of treatment by other methods. Situated favourably for radical extirpation, in a suitable patient, and operated upon by one absolutely qualified for the successful accomplishment of such work.

II.—HENRY T. BUTLIN, F.R.C.S.,

Surgeon to St. Bartholomew's Hospital.

WHEN I was invited by the officers of our Section to join in introducing this subject, I felt some embarrassment. On the one hand I could not well refuse to do so, not only because I was very sensible of the honour which was conferred on me by the invitation, but also because my name has been associated with the radical treatment of malignant disease of the larynx for some years past. On the other hand, I was sure that everyone likely to be present here would know perfectly my opinion on the matter, and I had nothing new to say. I therefore begged Dr. Delavan to undertake the task of introducing the discussion, and promised to speak on his address. The arrangement has answered better than I could have hoped; for the views which he has put forward are, in some respects, so different from my own, that the discussion bids fair to be both animated and interesting. His synopsis concludes with the proposition that the indications for the early treatment of malignant disease of the larynx are, "the prompt recognition of a malignant neoplasm of a given type, impossible of treatment by other methods, situated favourably for radical extirpation in a suitable patient, and operated upon by one absolutely qualified for the successful accomplishment of such work."

This proposition, and the whole tone of the paper, breathe a caution regarding the radical treatment of malignant disease of the larynx which is wholly opposed to my own views. I should lay down my own proposition in these terms: Every malignant growth of the larynx of intrinsic origin which can be dealt with, should be treated by a radical operation in the absence of a decided indication to the contrary, and the operation should be performed with the least possible delay.

And I would go further than this, and lay down a second proposition to the effect that every tumour of the larynx suspected to be malignant, of intrinsic origin, of limited extent, and apparently within reach of free removal, justifies an exploratory thyrotomy in a suitable patient in the absence of evidence of infiltration of the surrounding structures and of affection of the lymphatic glands.

I shall endeavour to show that these propositions are not extravagant. And, to this end, I must show that cancer of the larynx in properly selected cases can be successfully treated by a radical operation, and that there is no other method but a radical operation which can be confidently relied on to cure the patient. And, in the second place, that exploratory thyrotomy is singularly free from danger, and that thyrotomy, with removal of malignant disease of intrinsic origin, is not more dangerous than the severity of the disease will justify.

By a radical I mean a surgical operation, performed from the outside, and consisting of not less than the opening of the larynx by thyrotomy, and the free removal of the disease,

either with or without the removal of a part or the whole of the framework of the larynx. I have thus defined the term "radical operation," because I imagine that my definition of it is in accordance with the view which our officers had in mind in framing the text for our discussion, and that they did not intend to imply intralaryngeal operations and applications, which are nevertheless quite radical if they succeed in curing the disease.

As Mr. de Sautil has read a paper giving the whole of my cases of thyrotomy, I shall only so far deal with them as is necessary to the completeness of this paper. I have performed 10 thyrotomies on 9 patients for the radical treatment of intrinsic carcinoma of the larynx; 1 patient died of the operation; 4 patients suffered from local recurrence of the disease, and one of these was subjected to a second operation, which was again followed by recurrence; 3 patients were alive and well more than three years after the operation, and another patient is well and free from recurrence, but only about thirteen months have elapsed since the disease was removed.

I have twice performed the same radical operation for intrinsic disease suspected to be malignant. Unfortunately, the disease in one patient was thrown away without an examination, and I lost sight of the man after he left the hospital. The other patient is still free from disease at the end of two years. The tumour was red, fleshy and warty, and associated with thickening of the cord. But I was not sure, on microscopical examination, that it was malignant.

Other methods of radically treating carcinoma of the larynx may be dismissed in a few words. Constitutional treatment holds out no hope of cure. Serumtherapy is on its trial, and there is, unfortunately, very little yet to be said in favour of it as a curative agent. Intralaryngeal operations and applications, in spite of the able advocacy of Professor Fraenkel, are only possible in very rare cases. The uncertainty of the result and the probability that failure to completely remove or destroy the tumour may excite more rapid growth will prevent laryngeal surgeons from employing these methods in any but the most exceptional circumstances. The only treatment which holds out a reasonable prospect of success is to thoroughly expose the tumour and the parts in the midst of which it grows, and to remove it as freely as a malignant growth in any other part of the body should be removed.

Of the dangers of exploratory thyrotomy and of thyrotomy with the removal of intrinsic carcinoma, I can say from my own personal experience that they are singularly light. Although I have not often performed an exploratory thyrotomy without at the same time removing some of the soft parts within the larynx, I have now performed thyrotomy for innocent and malignant disease 28 times on 24 patients. Two of the 24 patients died, both from septic pneumonia, one of them after an operation for the removal of intrinsic carcinoma, the other after a much more severe operation for extrinsic carcinoma.

If the results which have been given are held to justify the propositions which have been laid down it will seem almost childish to press the further proposition that if an operation is to be performed for the discovery or removal of malignant disease of the larynx the sooner it is performed the better the prospect of success. But there is still necessity to urge this point. Even men skilful with the laryngoscope are sometimes disposed to watch suspicious growths too long, forgetting that the disease, without making much progress at its upper margin, may be spreading steadily below where its progress cannot be observed.

It only remains to be considered in what cases an operation is most likely to succeed, and what methods of after-treatment are likely to lead to the most speedy and safe recovery.

On these matters some of us have very clearly made up our minds. We operate in cases of carcinoma of intrinsic origin: that is in which the disease commences on the true cords, the ventricular bands, the ventricle of the larynx, or the parts below the cords, and scarcely ever venture to deal with a carcinoma of extrinsic origin. We select cases in which the disease is of limited extent, appears to be fairly movable, is situated towards or at the anterior part of the larynx, and in which there is no affection of the arytenoid regions or the interarytenoid folds. And we avoid the cases in which the larynx is filled with growth, in which it is

widened, and in which there is reason to fear that the disease has perforated the cartilage, and in which the lymphatic glands of the neck are affected.

And, in choosing our patients, we prefer those whose general health is good, and, particularly, those who are not liable to bronchial and pulmonary affections. At the same time, provided the season of the year be propitious, I have operated with success on more than one patient who has suffered severely before the operation from chronic bronchitis.

For several years past the greatest attention has been paid to the early diagnosis of malignant disease in such cases as those which have been indicated, particularly by our distinguished President. Greater attention is paid to slight impairment of mobility of the cords, to swelling beneath the growth, to ulceration of its surface. And the diagnosis is generally confirmed, where it is possible to remove a fragment for examination, by the aid of the microscope. But, Sir, after all we are still in this position, and are likely to remain in it for a good many years to come—that we must admit that there are three classes of cases: the first, in which any one and everyone can make the diagnosis; the second, in which the better-instructed or more experienced make it and the others do not; and the third class, in which the conditions are so obscure that no one can make the diagnosis unless the larynx is opened, and in some of which it is even then difficult to be sure of the nature of the disease.

It is for the necessity of exploration in these cases that I plead, and I do so in the full belief that operations for the exploration and for the removal of intrinsic carcinoma of the larynx are far less dangerous than they used to be.

I cannot but hope, and I think our President agrees with me, that the better results which have been procured during the last few years are in some measure due to the methods of treatment which I gradually thought out since the meeting of the International Medical Congress at Berlin. I remove Hahn's tube directly the operation is over. No attempt is made to close the wound. No tracheotomy tube is used, and no dressing is inserted into the interior of the larynx. But the surface is dusted with iodoform, and iodoform is frequently applied to the interior of the larynx. The external wound is covered with a piece of iodoform gauze which is changed as often as necessary, even 15 or 20 times a day. Instead of propping the patient up in bed, I take away all the pillows except one, so that the head lies low, and place the patient on his side, so as to diminish the tendency of discharges to pass down the trachea. During the first day or two, the patient is fed with nutrient enemata; but, usually on the day following the operation an attempt is encouraged to take fluids by the mouth. Water is first tried. The patient sits up and leans well forward, or leans over the edge of the bed, so that the fluid which passes into the larynx runs out through the wound immediately. If the water is swallowed without passing in any quantity into the larynx, beef-tea, milk, and soft solids are allowed.

In the last five years during which I have employed these measures, I have not lost a single case of thyrotomy; and, although I always feel that good fortune has something to say to these successful series of cases, I cannot but believe that the present series owes some part of its success to the after-treatment of the patients.

NOTE.—It is of the utmost importance that the iodoform powder should reach the surface of the wound in the interior of the larynx. Watching patients on whom I had operated, I discovered that this may be easily effected. When the patient swallows, the two halves of the thyroid cartilage separate to such an extent that the nozzle of an insufflator can be readily inserted between them, and the powder can be blown directly on to the raw surface.

I have a great opinion of the value of iodoform in the treatment of wounds of the mouth and larynx, but it is not likely to do good unless it reaches the actual surface of the wound and this is difficult to compass when the powder is insufflated through the mouth.

The discussion was continued by

The President (Dr. Semon), who insisted on the necessity of not confounding the expression "radical" operation with that of "laryngectomy." Thyrotomy had, in Mr. Butlin's

and his own hands, proved sufficiently radical in many cases to effect all that was necessary. In 62 per cent. of his cases complete recovery, in many cases with surprisingly good voice, had occurred; some of his patients had been operated on as long as three to four years ago, and in one case only had recurrence taken place. He would not deny at all that in future the indications for radical operation were likely to be drawn much wider than they were at present, and that extrinsic cancer with secondary implication of glands would also be found suitable for radical operation; but he felt that by early diagnosis and early operation a good many of the more severe operations would be entirely avoided. Finally, he expressed himself strongly against making local applications of any kind in cases of suspected laryngeal cancer.

Dr. A. HODGKINSON (Manchester) said: Whatever the ultimate results were, the operation must always be regarded as a serious one. The operation for the removal of the larynx, besides destroying the power of speech, does away with the capacity of fixing the chest walls by closure of the glottis, and so renders difficult the numerous muscular efforts which require a fixed condition of the chest walls for their full effect. Solis Cohen's case of complete removal of the larynx except as a marvellously successful result of the operation, precludes the possibility of the man following his usual employment; this inability may, I think, be largely due to the absence of the power of glottic closure. I think it is most important that patients about to undergo the operation should be made thoroughly aware of the utmost that can be expected from the result of the operation, together with the dangers of delay, even when diagnosis is doubtful.

Dr. R. H. WOODS (Dublin) said he could not agree with the proposition that operation is not admissible in extrinsic laryngeal cancer or where there was glandular enlargement. He pointed out that cancer of the breast was now undertaken most successfully when there was marked glandular affection, and why should not this apply to the larynx also? He then showed a patient the right half of whose larynx he had removed, and who had had separate chains of glands involved, one down the internal jugular and one up to the angle of the jaw (enlarged), and which he also removed. The operation was performed last April 1st, and there was no recurrence. He found the following method useful for removing blood and mucus from the wound. It consisted of a bottle with two tubes passing through the cork; to one an ordinary enema syringe was attached tail on, so that when the syringe was worked the bottle was emptied; to the other a flexible tube with a nozzle was attached. By this means a great deal of time was saved by avoiding sponging. As an antiseptic he was much in favour of tr. benzoin co. He did not approve of using acieable antiseptics, as chloride of zinc, in places where it might be directly washed away.

Dr. J. N. MACKENZIE (Baltimore) said: I have been greatly interested in this discussion. Dr. Delavan has treated the subject with that thoroughness and lucidity of statement which characterize all his literary productions. In this symposium of authority it is refreshing to have the sentiments expressed by Mr. Butlin. I accept his propositions, and go still further. If there be any chance of saving life I believe a preliminary thyrotomy justifiable, even in the presence of external glandular involvement, provided such involvement be not, on its face, too extensive. More than that: if, on thorough exposure of the parts—assuming, of course, that there be no serious contraindication to operation—it be found that the disease can be thoroughly eradicated, even if such eradication should involve more or less deep dissection of the surrounding tissues of the neck, it is far better to give the patient that chance of life than to allow him to drift on to certain and horrible death. As Jacobi said of opening the windpipe in diphtheria, if we saw a man hanging by the neck, we would not hesitate to cut the rope because the individual was in the last stages of tuberculosis or cancer. So in the class of case we are considering. We have no right not to give our cases every possible chance, even though the statistics of the past may possibly be against us. We want a new statistic—a statistic based on more accurate co-operative work, upon work done by men like Dr. Delavan and Mr. Butlin, which we can accept at once as *ex cathedra*. We, special workers in the

field of laryngology, must cast aside our pride, and recognize the fact that, while our achievements in the domain of endolaryngeal surgery may be brilliant, when it becomes a question of extirpation of the larynx, we must seek the aid and counsel of the general surgeon. We must work together the one dependent on the other. In this way we shall rob the operation of extirpation of the larynx of many of its terrors. What is meant by "radical operation?" Radical operation, as I understand it, means practically either partial or complete extirpation of the larynx, with or without removal of extrinsic circumscribed glandular enlargements. The proportion of cases in which the entire growth may be with certainty removed through the natural passages is infinitely small. Only one such instance has come under my observation. A man, aged 41, applied at my clinic at the Johns Hopkins Hospital two years ago for slight difficulty in swallowing. A small senile growth was found on the epiglottis and removed by one of my assistants. An examination made under the microscope by Professor Welch showed it to be a typical epithelioma. Two months later the man returned to the hospital. There was no trace of the original growth, but at the junction of the epiglottis and ary-epiglottic fold was a tumour about the size of a hazel nut, distinctly pedunculated, at times lying in the pyriform sinus, at others occupying the laryngeal vestibule. This was removed by means of the snare, and also found to be an epithelioma. I examined the man a few days before leaving America, and although over two years had elapsed since the performance of the second operation, there were no signs of laryngeal disease. This is the only case of pedunculated carcinoma of the larynx I have met with either in practice or literature. In this man the growths were distinctly circumscribed, within easy reach, and the disease was recognised at an early stage, so that all the conditions favourable to complete removal through the mouth were present. But this combination of circumstances is, unfortunately, not the rule. It is often impossible to limit laryngoscopically the extent of the disease. In the first specimen which I show you, on laryngoscopic examination the disease was apparently distinctly circumscribed to one side of the larynx, and it was only after complete removal of the organ that the discovery was made that the cancer had invaded the opposite side through a sort of cleavage, as it were, of the corresponding ala of the thyroid cartilage. Not only is it often impossible to map out with the laryngoscope the entire area covered by the disease; even after preliminary thyrotomy it is sometimes difficult, if not impossible, to define its exact limits. This was shown in a case of mine operated on by Professor Halstead last May in which the epithelioma was glandular in origin, and had not reached the surfaces over the entire area occupied by the growth. I do not wish for one moment to depreciate the value of the removal of laryngeal cancer by thyrotomy. To do so would be to fly in the face of all experience; but in the presence of the fact that it is sometimes impossible to limit the extent of the disease laryngoscopically, or soon after preliminary division of the thyroid cartilages (and I produce these two larynges in evidence), it often becomes a serious question whether we accomplish all to be desired by any operation short of complete excision of the larynx. Confronted by this uncertainty, the position of the surgeon is a most difficult and responsible one. Operations of this class should only be undertaken by surgeons of universally acknowledged skill and experience, and with a conscientious recognition of the ethical relations of operator and patient. In considering this question, I am profoundly impressed with the solemnity of the issue involved. It is not a theory but a condition that confronts us. Beside the question of saving life all other considerations pale into insignificance. Given a cancer confined to the larynx (even though the entire interior of that organ be involved) in a person in fairly good condition, and offering no absolute contraindication to operation, I would no more hesitate to recommend excision of the larynx than I would under similar circumstances hesitate to recommend excision of the breast. The conditions surrounding the two operations may be dissimilar and the dangers greater in the one than in the other; but to the patient it is the choice between danger and death. It is not so very long ago that excision of the breast was looked upon as a formidable operation, but this idea has

been dispelled by modern surgery, and especially by the brilliant results obtained by Halstead in this special field. If we can, with impunity, remove breasts, pectoral muscle, and axillary contents at one operation, we should certainly not hesitate, in suitable cases, to resort to the less formidable operation of excision of the larynx. In the hands of a skilful surgeon, the latter operation is not the ghastly procedure that we have been taught to regard it in the past, whilst its dangers are largely preventable. At the end of this century—if a century can ever end—we shall see a decided revolution of sentiment in regard to the radical operations on the larynx. I believe that the surgery of the future will reckon its cases not among the hundreds but among the thousands—that with improved technique, earlier diagnosis and therefore earlier radical surgical treatment, we shall achieve, in a very large proportion of cases of laryngeal cancer, the highest aim of our calling—the salvation of human life.

Dr. J. W. BOND thought Mr. Butlin's lines of selection of cases for operation most judicious; he himself laid special stress on involvement of the posterior commissure and top of oesophagus. As to gland involvement, if this were slight it was no contraindication of laryngectomy. He found palpation of the brim of the larynx useful in diagnosis. To him the mixed cases were the difficult ones in diagnosis. He had more experience of laryngectomy than thyrotomy, and he thought the operation would survive in suitable cases. The operation, like thyrotomy, is less dangerous if the patient is put with head low, so that blood runs towards the mouth and not into the lungs. He trusted to this more than to Hahn's tube. He had a pint of iodoform in ether, with tinct. benzoin co., which should be applied to the raw wound. As to Solis Cohen's case, he doubted if it would be possible to close the upper wound in many cases, especially if the oesophagus was touched. To him the moral of the discussion seemed to be that any patient over 40, with persistent hoarseness, ought to have the benefit of early skilled examination, and, if need be, prompt treatment; that thyrotomy ought to be done early in suspicious cases, for with laryngoscopy we only see in a glass one end or side of a growth, while in thyrotomy we see the whole surface to face, and can judge what to do.

Dr. SCANES SPICER said, that among the large number of cases of cancer of the larynx he had seen, owing to the late period at which they had come under observation he had only in one case felt justified in advising a radical operation. Even in this case the laryngoscopic appearances as to the extent of the disease were deceptive, for though apparently intrinsic and confined to the left side of the larynx, it was found, after thyrotomy, to have extended through the posterior wall, under an apparently healthy mucous membrane, then down the pharyngo-oesophagus and across the middle line. In this case it was decided to extirpate the the larynx and diseased tissues, but the result proved unfavourable within a week, for septic pneumonia carried off the patient. Was it better to extirpate diseased parts in such cases as this, or to close the wound up and leave the patient with a well-fitting tracheotomy tube?

Dr. DUNDAS GRANT urged the advantages gained by the performance of thyrotomy for exploratory purposes. He thought that the adoption of the sloping position with the head downwards rendered the use of Hahn's cannula unnecessary as exemplified by his own experience. In exploratory thyrotomy it was very necessary to hit off the anterior commissure with precision, and for this purpose he found it advantageous to introduce a curved director through openings above and below the thyroid cartilage, and to cut down upon it as a guide. If the anterior commissure is missed the features of the interior of the larynx are so distorted that an exact inspection of the growth is difficult or impossible. He expressed his indebtedness to the introducers of the debate for their valuable papers.

Mr. L. A. LAWRENCE suggested that in cases requiring complete removal of the larynx it might be quite as well always to cut off all connection of the respiratory tract from the mouth by stitching the trachea to the wound in the neck; this procedure would obviate all chance of food entering the trachea during the act of deglutition.

Dr. BRYSON DELAVAN, in reply, said: It is certainly a subject for congratulation that this discussion has served to

bring out more prominently than has ever been the case before the value of the work being done in London to-day in this department, the full nature and extent of which have not been sufficiently well known. It is likely that any difference of opinion which might exist between us would be more apparent than real, and would be based upon the fact that upon the Continent and in America the standards are set upon the basis of the older methods of operation, and not upon the advanced methods which have been adopted here. It is highly desirable, therefore, that your methods should be made better known, and the reasons for their unprecedented success thoroughly understood. There are two points in Mr. Butlin's argument to which I should especially refer. The first is the statement that every malignant tumour should be operated upon. Now, while I quite agree that this view is correct from the surgical point of view, I think that there are other considerations which should be thought of in connection with all such cases. It is impossible to ignore the personality of the patient, and to operate without any regard to questions other than the actual surgical condition. It is a very different thing to argue these matters in the abstract, and to take them home personally to ourselves. The most radical surgeon will sometimes see ample reason for modifying his views when he has personally considered a given operation with relation to himself. This I have found to be the case with laryngectomy. I would modify Mr. Butlin's statement by saying that every malignant tumour should be operated upon in cases in which operation is indicated, not only from the surgical point of view, but also from the probabilities present that the case may be ultimately a success in the fullest sense of the word. As to Mr. Butlin's second statement that in cases of suspected malignant disease of the larynx, in which the diagnosis cannot be made otherwise, an exploratory thyrotomy should be done, I am in full accord with him in the main, but think that the proposition should not be made without some qualification. It must be remembered that under the observation of an expert diagnostician, and in the hands of a skilful surgeon, this procedure may not only be admissible, but highly desirable. It will not do, however, for the idea to be promulgated, upon such eminent authority, that thyrotomy is to be lightly undertaken under ordinary circumstances and by ordinary operators. To sanction indiscriminate thyrotomy in cases of doubtful diagnosis in intralaryngeal disease would open the way for an amount of abuse the evils of which could hardly be over-estimated; and I must enter a strong plea for conservatism in this matter. It must be remembered that an expert opinion, based upon the widest experience, will often be mistaken by the outside world, and more latitude accepted from it than its originator had the slightest idea of suggesting. It is quite possible that more harm might be done by placing the operation of thyrotomy thus advocated in careless hands than good might be accomplished by its most skilful performance. The statement that because accidents have not occurred from the use of iodoform in a certain series of cases hardly answers the objection to the use of that drug, inasmuch as most serious results have followed its use in a sufficient number of instances to make it worth while for us to consider whether we may not eliminate in some way its dangerous properties, or else resort to other less toxic means. The statement also that cases have recovered who were subject to bronchitis will hardly do away with the reports of death following shortly after operation in patients who had suffered from this and similar complaints; and while the chances of such a patient may not be eliminated by them, it goes without saying that they may prove very annoying complicating factors, and therefore be well worthy of consideration. I am not aware that the upper aperture of the wound in the case of Dr. Cohen's patient simulates in any way the closure of the glottis, as it accompanies intense muscular action. For that reason, among others, probably, the patient has never been able to do any hard labour, or to undergo marked exertion since the operation. If some means could be provided him for supplying this deficiency, it would probably be of great assistance. The question alluded to by Dr. Wood—namely, the advisability of operation in cases where the disease has spread beyond the larynx, and where involvement of the glands is present—is a most important one in connection with

this discussion, although occupying as it does a place outside of the main question before us. While it is undoubtedly true that the best prognosis is likely to be afforded by the early extirpation of intralaryngeal disease, there are at least a number of cases on record in which more extensive operations have resulted for a certain length of time, in immunity from recurrence, and in decided relief to the patient. One of the very objects of my paper has been to stimulate such investigation upon this subject as would enable us to know positively whether these more severe operations were justifiable or not; and while the statistics resulting from them may not be as good as from the other class, it is nevertheless possible that a certain number of lives may be prolonged by them which otherwise would be quickly terminated. In the very nature of things there must always be a certain number of cases in whom disease is not early recognised, and who will therefore be obliged to submit to severe measures if the slightest help is to be afforded them. I am in hearty accord with the statements of Mr. Charters Symonds *et passim* of the matter. I am obliged to take issue with the statements of Dr. Mackenzie with regard to laryngectomy as compared with the excision of the breast. The two things are widely different, and it seems to me are not to be compared, either on anatomical, physiological, or surgical grounds. It was quite right that laryngectomy should have been called unjustifiable five years ago, in view of the published statistics, and, worse still, of the unpublished records, of an operation which had given such eminently bad results. Probably no other operation in surgery was less likely at that time to find general favour, in view of the wretched showing which it had made. In my own practice at that time I invariably explained the matter to my patient or to his friends; laid before him in the best manner that I could the possibilities of success, but explained to him frankly the chances of failure. In a few instances in which the cases were exceptionally promising the patients submitted to operation; with few exceptions they died in about the same limit of time that would have been the case had the disease pursued its natural course unrelieved by anything but tracheotomy. The simplest glance at the statistics showed that the chances on the whole were likely to be better without operation than with it, and no patient could have been criticised for declining to submit. It is a most fortunate thing that the progress which you have recently made should have so radically altered the state of affairs in this particular, and so vastly improved the prognosis. That the operation under any circumstances is easy and simple, as Dr. Mackenzie has suggested, is a proposition which I cannot accept. It may be not difficult to remove a larynx or a part of it; the operation, however, is a very small part of the whole story. I cannot help believing that a larger experience on Dr. Mackenzie's part will convince him of the desirability of a more conservative view. I have always been strongly in favour of the performance of tracheotomy several days prior to opening of the larynx, and believe that many dangers may be prevented by the early introduction of the tracheal tube. Ten days is not too long a time beforehand. I agree most cordially with the opinion of the Chairman, that early operation should be done in all cases where it is possible, in order to avoid the necessity of the more extensive operation which would be required at a later period. As before stated, however, I do not believe that all surgical interference should be avoided in some of the later cases. With regard to local applications in epithelioma of the larynx, I have already stated that they are ineffective, excepting in certain cases in which operation is refused and in which it is desirable to delay the progress of the growth as much as possible. It can never be curative, of course, but it may succeed, as I have known it to, in retarding the progress of the disease. The effect of applications of alcohol upon simple papilloma has been so marked in my experience as to make it well worth while to call your attention to it. It is conceded that at a certain stage of some growths, apparently of a papillomatous nature, it is impossible to say with certainty whether the tumour is a simple one or whether it is malignant. The most innocent looking papilloma may ultimately prove to have been the beginning of grave malignant disease. All apparent papillomas, however, are by no means necessarily malignant. To perform thyrotomy at once upon every papillomatous

growth which presented itself would not be advocated by anyone. There are some cases in which a certain amount of delay is absolutely unavoidable, unless we are to rush into the most reckless kind of surgery. I see no reason why in such cases some treatment similar to the alcohol treatment should not be employed, in view of the probability that the case is benign. It would be dangerous advice to say that thyrotomy should be done in every case of apparent papilloma and at the first moment such case presented itself. I cannot speak in too earnest terms of appreciation of the admirable work which you are doing in London. It appears to be far in advance of that done in any other part of the world. I congratulate you upon it, and trust that you may continue with unflagging enthusiasm in its successful pursuit.

(To be continued.)

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Tuesday, October 22nd, 1895.

PRESENTATION OF REPORT OF THE COMMITTEE APPOINTED TO INVESTIGATE THE MEDICAL CLIMATOLOGY AND BALNEOLOGY OF GREAT BRITAIN AND IRELAND.

THE CHAIRMAN, Dr. W. M. ORD, presented the first volume of this report to the Society, and in so doing described the scope of the work that had been done. He paid a high tribute to the indefatigable exertions of the Secretary, Dr. A. E. GARROD, and referred to the careful and valuable work done by the contributors.

Sir E. H. SEEVERING spoke in high terms of the report that had been laid before them, and expressed a hope that similar committees for the investigation of important medical problems should be instituted from time to time by the Society, and that such work should, if possible, be endowed.

Dr. W. H. DICKINSON thought it would be a gracious act to present to those medical practitioners in the country who had contributed reports to the volume copies of that part of the work. He cordially endorsed Dr. Ord's remarks about the debt the Committee owed to its Secretary, Dr. Garrod.

On the motion of the PRESIDENT, a cordial vote of thanks was passed to the Committee for the report.

POSTURE IN ITS RELATION TO SURGICAL OPERATIONS UNDER ANÆSTHETICS.

Dr. F. HEWITT and Mr. A. M. SHEILD, who read this paper, pointed out that the posture of a patient prior to, during, and after a surgical operation under an anæsthetic was a matter of considerable importance to the surgeon, to the anæsthetist, and in many cases to the patient himself. The subject was discussed under the following headings: 1. The Posture of the Head in its Relation to that of the Trunk. Extension, flexion, and rotation of the head were considered. Stress was laid upon keeping the head, whenever practicable, in the longitudinal axis of the body. The circumstances which favour the entrance of blood into the larynx and trachea were defined. 2. The Influence of the Force of Gravity upon the Circulation and Respiration. The observations of Snow, the Hyderabad Commission, and of Dr. Leonard Hill, were quoted; and the administration of anæsthetics to patients in the sitting and semi-recumbent postures was discussed. 3. The Postures of Surgery individually considered. (a) The dorsal, supine, or horizontal posture. The advantages of keeping the head turned to one side; and the disadvantages of allowing a patient to lie face upwards, and with the head slightly extended. (b) The dorso-lateral posture. (c) The lateral posture. Its advantages in most major operations within or about the mouth and nose. Operations for empyema. (d) The lithotomous and prone postures. Necessity for caution when patients of certain types are placed in these positions. (e) The semi-recumbent posture. Its disadvantages except in a few special cases. (f) The sitting posture. (g) Special postures, including the lithotomy, the semi-inverted, Trendelenburg's, and the knee-elbow. 4. The Posture of the Patient after the Operation. Remarks were made concerning the raising of patients for bandaging, etc., the application of

bandages after empyema operations, and the appropriate positions for patients when the circulation is feeble. The authors strongly urged the advantages of at once turning patients upon the side after an operation, provided, of course, that there were no special contra-indications.

The President, in congratulating the authors on their paper, said the subject was one of comparative novelty, and had not been previously so fully treated. The paper was full of careful criticism and valuable practical hints.

Mr. R. GILL congratulated the authors on having chosen a topic of wide interests and bearings, but would have preferred a less vague and generalised manner of treating the subject. He could not agree that position was so important, or that some postures were so dangerous as the authors said. He had given chloroform in almost every imaginable position without any bad results. In illustration he quoted cases where anaesthesia was induced in the lying down position, which was then changed for the sitting-up position to allow of laryngoscopic examination. The authors had said that in over-extension of the neck there was danger of blood and vomited matters entering the larynx; he considered the entry of blood very rare, and had never known vomited matters pass into the larynx.

On the motion of Dr. SCANES SPICER, seconded by Dr. A. F. SANSON, the debate was adjourned until the next meeting of the Society.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

EDWARD NETTLESHIP, F.R.C.S., President, in the Chair.

Thursday, October 17th, 1895.

PRESIDENT'S ADDRESS.

THE PRESIDENT began by thanking the members for the honour they had done him in electing him President of the Society. He took this honour, however, as not only, nor even chiefly, for himself. It was his good fortune in the spring of 1880 to be much thrown with several earnest and enthusiastic workers in ophthalmology, whose joint efforts led to the formation of the Society. They were especially indebted to Brailey, Stephen Mackenzie, and the late James Adams for the movement that secured the weighty approval and leadership of Sir William Bowman in launching this almost the first of the special medical societies in this country.¹ If to-day it was his (the speaker's) lot to preside at their meetings, he owed that distinction chiefly to his association with those who created the Society. Coming as he did after a series of Presidents, all older than himself, all vastly his superiors in merit, many of them men whose names had been household words in the profession all over the world, he felt but little confidence that he would be able to discharge fully the duties of his high office. He begged indulgence for defects of which he was only too well aware—defects brought home as they were with especial force when he remembered the urbanity, dignified address, impartiality, and diligent attention to all the interests of the Society that were so conspicuous in his immediate predecessor. As the Ophthalmological Society was almost the first of the special Societies, so it was still, and must always remain second to none in practical importance and breadth of interest. The Society was a very important educational centre, comprehending in itself the spirit of all that was best in the teaching, research, and practice of the ophthalmic institutions of the country. Every difficult art or craft must be more or less specialised if its achievements were to be as good as possible, for art was long, difficult, and elaborate and ophthalmology offered no exception. The necessity of keeping their knowledge fresh and growing, of holding their minds open and their mental grasp broad and vigorous had to be reconciled with the limitations of personal capacity, endurance, and opportunity. Thus specialist societies and special hospitals, leavened as much as possible by variety of membership, and stimulated by friendly rivalry, were necessary for thoroughness of work. They were not, however, incompatible with breadth of view and simplicity of aim; for the narrowing influence of specialism in daily work has not been

increased, but diminished, by meeting often and discussing freely, especially when many of their members were largely engaged in other branches of professional work. What was true of the scientific value of special societies was in the main true also of well-ordered special hospitals. Far in the latter practical work and scientific research could often be elaborated to a degree impossible in the corresponding departments of the general hospitals, where the interests of the great medical and surgical divisions must always be supreme. The special departments could not have taken, and could not now maintain, the high standard of their work and teaching, did not facilities exist for associated work and mutual enlightenment at the special hospitals and special societies. Lest the words just used should fail to convey fully what he wished to express as to the respective functions of the departments and the special institutions, he would venture at the risk of being wearisome, to enlarge a little. During the last thirty or forty years the hospitals and medical schools had gradually made provision—often on a very liberal scale—for the separate charge of maladies that, by common consent, required particular or difficult methods of diagnosis and treatment. He wished emphatically to express the warmest appreciation of the very high value of the special departments, and equally to guard himself against overlooking certain dangers to which general hospitals were particularly prone. All now admitted that the special departments were necessary at every hospital with a medical school; that the teaching of the elements of, for example, ophthalmology—to mention only one subject—was essential; that the advantage of constant association in work with his medical and surgical colleagues was invaluable even indispensable, to the specialist in his own branch; and that his work reacted favourably on that of others. Probably few, if any, doubted that special hospitals also would continue to be necessary, and that they would command respect as long as by advanced teaching, pathological research, and all other suitable methods they strove for the furtherance of knowledge and skill in their own subjects. Neither the departments nor the institutions for special diseases could stand alone without danger of one kind or another. The best way, as it seemed to him, of combining the strong points in each and avoiding the weak places in both, would be found when each officer of a special department should also be attached to a special hospital; and when the staffs of the special hospitals were composed of men who also held office in a special department. The work hitherto done by the Society had, they might justly say, been of considerable importance. Some far-reaching discussions had taken place, and several valuable collective reports had been made; their *Transactions* contained a great store of important records and observations, and many of their illustrations were, he believed, second to none in faithfulness and beauty of execution. Whilst he yielded to none in admiration and respect for the immense value of much of the work that had been and was published abroad, he thought they occasionally allowed their appreciation of foreign research to obscure the merits, either in time or in importance, of work done at home. They could not be too careful to assign the claim of priority, whether in time or in merit, correctly, even when it was due to their own countrymen. The material the Society had to deal with was inexhaustible, and their continued success was assured if they showed that they could adapt themselves to any changes in the character or method of their work that the times might demand. How often in ophthalmic work it was necessary that researches, either clinical or pathological, which seemed final had to be repeated in a different and better way. How true it was that there was almost unbounded room for the re-examination of many everyday practices and beliefs; for the filling up of many gaps in their knowledge; for the observation of the effects of particular remedies separated as far as was proper and possible from complicating circumstances, for the pathological examination of many conditions that they knew hitherto chiefly through the clinical appearances. The President then referred in feeling terms to the loss the Society had suffered since its last meeting in the death of their distinguished member, Dr. John Syer Bristowe, to whose great merit as a physician and fine character as a man he paid an eloquent

¹ The Ophthalmological Society of Great Britain was formed in 1880 and the Obstetrical in 1888. J. B. Bailey, BRITISH MEDICAL JOURNAL, 1895, vol. II, p. 101.

tribute. He next proceeded to speak of certain points in the pathology and surgery of the organs of vision, which he thought might fruitfully be made the subject of fuller investigation by members of the Society.

FOUR CASES OF BILATERAL GLIOMA OF THE RETINA CURED BY ENUCLEATION OF THE TWO EYES.

This paper was read by Mr. TREACHER COLLINS. He first referred to the paper in which Mr. Lawford and he had shown that there was no authentic record of a case in which a gliomatous growth had recurred later than three years after enucleation of an eye for that disease. He related histories of the following four cases:—Case I. A boy who had his right eye excised for glioma when 5 months old, and his left eye three years later. Three and a-half years after the removal of his second eye he was alive and well, and there was no sign of any recurrence. Case II. A girl whose left eye was excised for glioma when 5 months old, and right eye nine months later. She was seen to be in perfect health four years and seven months after the removal of the second eye. Case III. A girl whose left eye was excised for glioma when 10 months old, and right eye thirteen months later. Four years after removal of the second eye she was in good health, and there was no sign of any recurrence. Case IV. A boy both of whose eyes were excised for glioma when he was 1 year and 4 months old, the left being a shrunken one. Three years and three months later he was in good health, and had no sign of any recurrence. Seeing that all these four patients were alive and in good health, without any sign of recurrence, after an interval of more than three years from the date of removal of the second eye—that is, after the longest interval at which there is any authentic record of a recurrence having occurred, he thought he might justly claim that they were cured.

Mr. LANG had had three cases, two of which were described by Mr. Collins; in the third case one eye was excised at 15 months of age; the growth was discovered in the second eye nine months later. The parents refused to have the eye excised, but it was excised later on account of pain. There was then a secondary nodule in the neck. The child did not die till 5 years of age.

Mr. LAWFORD quoted a case in which the first eye was excised at the age of 2 months; two years and a half later the second eye was affected. The parents refused to have the eye removed till three years after, when the nerve was involved.

Mr. PRIESTLEY SMITH had seen a child in a blind institution who was said to have both eyes removed for cancer in infancy; it was probably glioma.

The PRESIDENT had had another case besides those quoted by Mr. Collins, in which both eyes were excised before 1892, and the boy was still in good health.

DETACHMENT OF CHOROID.

Mr. C. DEVEREUX MARSHALL read this paper. Three cases had recently come under his notice. The first case was the eye of a lad aged 20, who suffered from glaucoma. Iridectomy was done, and three days later the eye became very painful, owing to a large hemorrhage having taken place beneath the choroid. On examining it after removal of the choroid and retina were completely detached. The second case was that of a man aged 60, who had suffered from glaucoma. Iridectomy was done, but the eye shrank and was removed. There was an extensive detachment of retina and choroid, the sub-choroidal space was filled with new tissue, in which cyst-like spaces were developed. Microscopic examination proved it to be the much thickened lamina suprachoroides and lamina fusca; the small spaces contained pigment and were probably lymph channels. The third case was that of a man aged 68, who had a cataract extracted; the V. = $\frac{1}{2}$, and J. 1 afterwards, but six months later the vision failed. As it was feared that the eye contained a new growth, it was removed. There was almost complete detachment of choroid and retina; the only place where the coats remained attached to the sclerotic were at the places where the vessels and nerves penetrated; thus there were four large balloon-shaped detachments, the subchoroidal space containing nothing but serous exudation. The first case is similar to that condition met with after an accident resulting in the loss of a large quantity of vitreous, and it is occasionally seen after cataract extraction, but here

the hemorrhage probably did not come on for three days after the operation, and there was no loss of vitreous. The last case is the most uncommon. The detachment probably came about as the result of (a) hyalitis leading to shrinking of the vitreous; (b) choroido-retinitis; (c) serous exudation poured out between choroid and sclerotic. The diagnosis previous to removal is most difficult. The tension is usually diminished, and this is the most distinctive feature between the simple detachment and that due to a growth.

Mr. JESSOP asked if there had been any cases recorded in which there was diminished tension with an intraocular tumour.

The PRESIDENT wished to know if there were on record cases in which a simple detachment of the choroid had been diagnosed during life. He thought it was not very uncommon to get diminished tension in the very earliest stages of intraocular tumour.

Mr. PRIESTLEY SMITH and Mr. TREACHER COLLINS had both looked for cases of intraocular tumour with diminished tension without success.

CARD SPECIMENS.

The following were the card specimens: Mr. KENNER CLARKE: (1) Rare form of Nystagmus; (2) Orbital Tumour. Dr. MOTT and Mr. TREACHER COLLINS: Case of Exophthalmos with Trigeminal Hemianalgesia. Mr. KENNETH CAMPBELL: Case of Anophthalmos. Mr. A. S. MORTON: Suelien's operation for Symblepharon. Mr. HIGGINS: Unusual form of Conjunctivitis. Mr. LAWFORD: Case of Retinitis Circinata.

LARYNGOLOGICAL SOCIETY OF LONDON.

FELIX SEMON, M.D., F.R.C.P., President, in the Chair.

Wednesday, October 9th, 1895.

CASES.

DR. LEONARD ROBER showed a case of Congenital Syphilis of the Soft Palate, Pharynx, and Larynx in a girl aged 21. Six months ago she lost her voice. Three years ago sores appeared on the upper lip and nose. The ulceration of the face lasted twelve months. Two swellings then appeared on the right arm. The lower end of the radius was now much thickened. The epiglottis and false cords were thickened, and there was some infraglottic swelling. The general opinion of the members appeared to be that this was a case of lupus.—Dr. FERNISS POTTER showed a man, aged 28, with Tertiary Syphilis. The uvula was almost detached from the soft palate, and was adherent to the left posterior pillar of the fauces. The epiglottis was almost destroyed. The rima glottidis was much narrowed. A polypoid growth was attached to the epiglottic stump. The patient improved greatly under iodide of potassium.—Dr. SCOTT showed a case of Cicatricial Obstruction of the Anterior Nares. Mr. BUTLIN suggested that a plastic operation should be performed. Dr. DUNDAS GRANT would if this failed try cutting the columna and introducing a silver saddle to raise the tip.—Mr. C. SYMONDS showed two cases of Tuberculous Disease of the Septum. (1) A man, aged 48, who fifteen months ago had a small pimple in the left nostril. Soon after the nose became blocked. The man was invalided out of the army for consumption. No syphilis. Father died of phthisis; mother now ill with the same disease. No definite physical signs. (2) A boy, aged 16, had had his nose blocked on the right side for eight months. No history of accident or phthisis. Lungs healthy. A mass projected from the anterior part of the cartilaginous septum. In the left nostril there was some ulceration of the septum. Mr. C. Symonds also showed a man, aged 50, whose left vocal cord had been removed for cicatricial stenosis. Tracheotomy was performed six years ago. The cords were then red and swollen. Some tags were removed and the tracheal wound closed. Two years after tracheotomy had again to be performed and later the thyroid was divided. After this there was great stenosis from irregular contraction, rendering the tube necessary. In February, 1895, the thyroid was again divided, and the left cord and its muscles removed; and in September the tracheal fistula was closed. The man now breathed well, and his voice was gaining power.—Dr. W. HILL showed a woman with Frontal Sinus Disease. Since showing the case previously he had opened the sinus and drained the infundibulum.

bulum, but had found it impossible so far to establish efficient drainage. Dr. TILLY and Mr. BAKER suggested that Grünwald's method should be employed.

SPECIMENS.

The following specimens were shown: Dr. KANTHACK: Carcinoma of the Larynx; Carcinoma of the Pharynx; Diffuse Papillomatous Hyperplasia of Laryngeal Mucous Membrane in a Child; Necrosis and Ulceration of Epiglottitis in a Case of Typhoid Fever.—The President: Large Nasal Polypi removed from the Right Tonsil of a Lad, aged 19; Tuberculous Ulceration of the Soft Palate, Uvula, and Right Tonsil and Larynx; Very Large Laryngeal Papilloma; a True Myxoma of the Larynx; Syphilitic Endotracheitis.

LIVERPOOL MEDICAL INSTITUTION.

J. W. WARBURTON, M.D., Vice-President, in the Chair.

Thursday, October 17th, 1895.

CASES.

Mr. PAUL described the case of a woman, aged 55, from whom he had removed a very large Villous Papilloma from the Rectum. The symptoms were chiefly bearing-down pain and constant desire to defecate, with passage of blood and mucus. They had existed for over eight years. The operation was followed by slow but good recovery. The tumour had the typical structure of villous papilloma, and did not infiltrate the submucous tissue. Mr. Paul believed that these growths were more rare than is generally supposed, and that they were not liable to become malignant. Mr. RUXTON PARKER agreed with Mr. Paul that a purely villous papilloma was not likely to become malignant, and that the villous tumours which became carcinomatous were probably carcinomata from the first, but liable to be mistaken for the innocent form of villous growth.—Mr. THELWALL THOMAS showed a young man of 18, in whom he had diagnosed Hydrocephalus, possibly produced by a cerebellar tumour on the right side. There was a history of increasing headache for eighteen months, extreme ataxia causing falling to the right side, nystagmus, giddiness, double vision; paralysis of right fourth nerve, double optic neuritis, occasional vomiting; head 25 inches in circumference. The right cerebellar fossa was opened, the dura mater bulged and was very tense, and it did not pulsate, and so was incised. The cerebellum still protruded, so the finger was inserted to explore. No tumour was felt, but a membrane across the space under the cerebellum, through which the finger readily passed, liberating a quantity of clear fluid; the medulla and the floor of the fourth ventricle were distinctly felt. The bone was not replaced. The headache disappeared, and he quickly regained all his faculties, and now (six months after the operation) he is apparently quite well. Dr. GLYNN, who had suggested operation to Mr. Thomas, thought at the time that the case was one of cerebellar tumour. It was remarkable that the operation should not only have been followed by temporary relief, but by permanent recovery. It was possible that a posterior meningitis had been followed by adhesions in the membranes in the neighbourhood of the fourth ventricle, and so caused hydrocephalus. Messrs. RUXTON PARKER, MURRAY, and LARKIN also made remarks on Mr. Thomas's case, the last two speakers suggesting that the case was probably one of cyst of the cerebellum.—Dr. STOFFORD TAYLOR showed a case of Congenital Syphilis in a man aged 24. It appeared that a "sore" came on his upper lip while in the River Plate about four years ago, and this slowly spread, invading both cheeks, producing ectropion of the left eyelid, and causing complete loss of nose. It also affected the left half of the scalp and the alveolar process of the upper jaw. His present condition is best described as syphilitic lupus. Rapid healing took place under the influence of iodide of potassium and mercurial dressings.

EXOPTHALMIC GOITRE.

Dr. ABRAM read a paper on exophthalmic goitre, with special reference to the thyroid theory of the disease, and the treatment of the affection by operation. A short description of the symptoms was given, followed by a critical examination of the various theories advanced to explain the disease. The thyroid theory was held to be the most satis-

factory. Two operations—partial thyroidectomy or ligature of the thyroid arteries—were suggested as fulfilling the conditions necessary for the relief or cure of the disease.

Dr. CARTER believed that violent emotion sometimes caused the disease; he was unable to accept any absolutely inclusive theory, but thought there must be a variety of causes which would probably account for variations in clinical history. He mentioned cases where cure had taken place under medical treatment. On two occasions he had seen marked cases without any detectable enlargement of the thyroid.

Mr. PAUL said he had operated on two cases for Dr. Barron. The first was only moderately severe. Here he divided the thyroid isthmus, and the case was distinctly benefited. The second operation he performed ten days ago. This was a most severe case, and he removed the entire right lobe, which weighed 2½ ounces. The bleeding was less than in the case of large adenomata. The change in the patient was most remarkable; in three days the remaining half of the thyroid was not visible; the temperature and pulse had fallen, and the exophthalmos was receding.

Dr. BRADSHAW had tried the prolonged application of ice-bags to the thyroid, and also counter-irritation with red oxide of mercury ointment, but without benefit.

Mr. G. HAMILTON said that in many cases goitres could not be operated upon owing to the enormous vessels and sinuses present.

Dr. BUCHANAN said that the symptoms resulting from artificial removal of the thyroid, the pathological atrophy in myxodema, and those produced by excessive administration of thyroid extract, so much resembled the symptoms of exophthalmic goitre, that this much supported the idea that exophthalmic goitre was due to over-activity and excessive secretion of the thyroid gland.

Drs. GLYNN, CATON, LOGAN, DAVIES, GIVEN, and SHERRINGTON also took part in the very interesting discussion on Dr. Abram's paper.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting on October 17th, Mr. VACHER, the President for the coming year, gave an address on the Prevention of Epidemics, which were evidence of the failure of our efforts at important points, as the speedy removal of excreta and refuse, early notification of all cases of infectious diseases, isolation, and disinfection. In most towns in the south water carriage by sewers had superseded all "storage" systems, but in the north the midden was dying hard, yet whether in the old form of "combined midden," or as a smaller private cesspit, or a pail, the retention of excreta amid dwellings was inexcusable. Notification was invaluable in checking the first beginnings of an epidemic, but it must be general, prompt, and rigidly enforced. It was useless when a large proportion of cases were not reported at all, or not until the disease had nearly run its course, yet there were places where medical men sent them in in batches at intervals of two or more weeks, and others where the deaths from puerperal fever, diphtheria, and "membranous croup" outnumbered the cases notified. Dual notification was a dead letter, not one in a thousand being from a householder, and it was, therefore, clear that mild cases without medical attendance escaped. The powers conferred by successive Acts from 1866 to 1893 on local authorities for isolation of infectious diseases had too often been but insufficiently exercised. Arrangements with endowed or other general hospitals were rarely satisfactory, and the inadequate accommodation usually provided had, whenever an epidemic broke out, to be supplemented by tents, huts, and the like, in which ventilation and warming, sanitation and nursing were difficult, while the expense delayed the provision of larger permanent buildings. Hospital districts should not be too small, and there should be one bed at least for every 1,000 of the population, with separate small-pox and observation wards, and accommodation for families during disinfection of their houses. Disinfection, however, as mostly carried out—that was to say, sulphur fumigation of any kind—was a farce; general instructions to the occupier as to stripping and lime washing were of little use, while the furniture, the chief retainer of infection, was ignored. It was not the air that needed disinfection, but walls, carpets, furniture and

bedding. Lime washing, sublimate (1 in 1,000) spray and swabbing of walls and floors, with disinfection by steam, or by boiling water of all fomites, was the only effective means; and since a very efficient steam oven could be put up complete for £75, no authority could excuse its neglect on the score of expense. Baths for disinfecting persons, while their clothes were being steamed, should be provided at the same station.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this Society was held in University College on October 8th. Mr. A. W. PRICHARD, President, delivered an Inaugural Address, which dealt chiefly with the surgical aspect of disease and accident as occurring in the boys of Clifton College. He mentioned numerous interesting cases, and insisted that there was a great benefit obtained by the following out of the course of athletics and games as arranged at that great public school.—Mr. PAUL BUSH (Honorary Secretary) read his annual report, as did also Mr. L. M. GARFINKEL (Assistant Editor and Honorary Librarian). These reports were adopted.—The following officers were elected: *President-elect*: Dr. Aust-Lawrence. *Honorary Secretary*: Mr. J. Paul Bush. *Committee*: Dr. Mitchell Clarke, Mr. Dacre, Mr. W. H. Harsant, Dr. B. Rogers, Dr. Shaw, Mr. Munro Smith. *Library Committee*: Mr. L. M. Griffiths, Dr. Parker, Dr. J. Swan.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this Society was held on October 10th, Dr. PORTER (President) in the chair.—The President delivered an address in which he dealt with many of the ethical questions now agitating the profession. In reference to medical etiquette he said that it was very desirable that certain canons or broad principles should be laid down decisively, and everyone entering the profession should be required to subscribe to them. He then dwelt upon the necessity for a more representative form of government in the profession, on similar lines to the Incorporated Law Society. He also advocated very strongly the adoption of the "one portal" principle, both as regards the entrance examination and the tests of professional fitness. There would then be no necessity for the representation of the universities and licensing bodies, as such, upon the governing body of the profession. They would then simply confer their titles on their own terms upon those who were already qualified medical practitioners. He believed, too, that one uniform standard of examination would tend to exclude some undesirable candidates for admission to the profession. The President next dealt with the question of the abuse of medical charities, advocating a more searching inquiry on the part of the hospital authorities into the circumstances of those who presented themselves as out-patients, and suggesting that in some cases the exaction of a small charge might be advisable, though he was not in favour of admitting cases indiscriminately as paying patients. State support or State aid he was not in favour of, but thought that registration and periodical government inspection of all hospitals, dispensaries, and similar institutions, would have a very salutary effect, especially if this were accompanied by the power to close all such institutions as were considered unnecessary or administered in an improper manner. The State had a duty to perform in preventing institutions which were conducted for personal ends being falsely marked with a title calculated to deceive the public and divert support from more deserving objects.—The President concluded with some remarks on the national importance of medical education and the public side of medical work, commenting upon the very inadequate acknowledgment on the part of the public of their indebtedness to the medical profession as a body.

MEDICAL SCHOOLS OF PHILADELPHIA.—The *Medical News* gives the following statistics as to the several medical schools of Philadelphia. The University of Pennsylvania has 900 students as against 885 in 1894-95; Jefferson Medical College has 725 as against 700; the Medico-Chirurgical College has 320 as against 239; the Hahnemann Medical College has 286 as against 290; the Women's Medical College has 200 as against 175; and the Philadelphia Polyclinic 160 as against 130. The total number of students in all the medical schools of Philadelphia this year is, therefore, 2,610 as against 2,945 in the previous session.

REVIEWS.

ESSAYS ON HEART AND LUNG DISEASE. By ARTHUR FOXWELL, M.A., M.D. Cantab. London: Charles Griffin and Co. 1895. (Demy 8vo, pp. 490. 12s. 6d.)

THESE admirable essays have for the most part been previously published, but have been collected and carefully edited by the author so as to ensure that they represent his present opinions, and are also consistent with the medical knowledge of to day.

Unquestionably the best, and in our opinion that which gives the author a right to a niche in the temple of medical science, is the group of papers on the Condition of the Vascular System in Anæmic Debility, wherein he gives an excellent explanation of the production of the heart murmurs met with under these circumstances. It is without doubt the most satisfactory solution of the problem hitherto attempted, and appears to be very likely the true one.

The essay on Catarrhus is an attempt to enter the field of general pathology which will undoubtedly provoke controversy. Catarrhus is regarded by Dr. Foxwell as a specific infective process of wide range and varying intensity, often accountable for the most diverse visceral complications, so that under this heading must be included such diverse diseases as meningitis, pneumonia, pericarditis, peritonitis, nephritis, etc. In other words, cases at present regarded as primary, or, at least, unexplained examples of meningitis, etc., receive, at Dr. Foxwell's hands, the title catarrhal, and are attributed by him to the influence of this common infection. Is not such a conclusion somewhat premature, and should we not in the first place have some better evidence of the specific nature of catarrhus? Is it not probable that many different infective organisms can cause catarrhus, and that we have at present no means of differentiating them or their effects?

These essays will be appreciated by all who care for writings which are eminently thoughtful, yet withal practical in their bearing.

TREATMENT OF ENTERIC FEVER ON THE ANTISEPTIC PRINCIPLES. By Surgeon-Lieutenant-Colonel R. H. QUILL, A.M.S. Reprinted from the *Indian Medical Gazette*, No. 7, July, 1895.

IN this excellent and temperately written pamphlet the author describes the treatment of enteric fever which he has adopted during the past two years. Out of 36 consecutive cases, many of great severity, there were only 2 deaths, 1 from perforation, the other from hyperpyrexia with nervous exhaustion. Gratifying as this result is the number of cases is obviously too small for any final conclusions to be drawn, though sufficient to justify a careful and extended trial of the treatment. Surgeon-Colonel Quill makes milk the staple article of diet, and justly lays stress on the examination of the stools as a guide to the prevention of over-feeding. He adds to each 6 ozs. of milk 2 ozs. of lime water; in addition to this each pint of milk receives an ounce of a mixture containing 10 grains of bicarbonate of soda and 5 grains of common salt dissolved in water. We may here point out that the chemical action of this mixture would be to predominate chalk from the lime water so that the efficiency of the latter would be seriously impaired. Lime water alone, or barley water with an alkaline mixture, is to be preferred as a diluent for the milk.

The author treats distension or hæmorrhage by an ingeniously-constructed ice-tray suspended like Dr. Fenwick's ice-craddle; he believes in the use of calomel in the early stage of the disease, giving 2 grains every other night for three times if the case is admitted during the first eight or nine days. He considers that its action is antiseptic as well as purgative, and he uses it in $\frac{1}{2}$ -grain doses as a remedy for constipation during the course of the disease. The special antiseptic treatment advocated in this paper is the administration every two or three hours of a mixture containing 3 minims of acid carbolic, puriss. (Caivert) with 10 minims of compound tincture of chloroform made up to an ounce with tinct. cascarnum, co., syr. benzoinum and aq. chloroform and given with an ounce

of iced water. No carbolaria resulted from this treatment; the chloroform was employed in consequence of Werner's experiments showing its toxic effects on the enteric bacillus. Surgeon-Colonel Quill considers that the antiseptic treatment will reduce the mortality of enteric fever in India from its present figure—50 to 30 per cent.—to 5 to 12 per cent. While admitting the value of the method he adopts we should like to be absolutely certain of the fact that the mixture actually reaches the seat of the disease; it seems quite possible that such easily absorbable substances as carbolic acid and chloroform would pass out from the alimentary tract before reaching the lower portion of the ileum.

This is a point for future investigators to decide, and until it is settled the definitive value of Surgeon-Colonel Quill's interesting communication must remain undecided.

VIVISECTION: CAN IT ADVANCE MANKIND? By O. S. OAKLEY. London: J. Davy and Sons. 1895. (Demy, 8vo, pp. 58. 6d.)

In this essay, advocating the prohibition by law of all experiments on animals, there are several paragraphs that are well worth reading. Mr. OAKLEY has much to say that is of interest regarding the greatness of science, the problems of slavery and of sport, the supreme importance of a high and ever higher standard of morality for the nations, and the far-reaching power of one good life over many; and he has taken a great deal of trouble over his work, so that it is more pleasant reading than the rubbish that is printed in certain *scientific papers*.

But this is all that can be said for it. He has not studied his subject; he has no sense of his own ignorance and no humility. To him experiment on animals means "cutting up animals alive," and there are special young men who "devote themselves to cutting up live dogs leisurely and without wincing." Again, he says, "If it did not hurt them, and hurt them intensely, the demonstration could be of no value." And thus he sinks lower and lower, talking about the "voiceless corridors" and "exquisite secrecy" of the "new holy inquisition." And all this nonsense is written by a man who has not even read the Act, or the inspector's annual reports. There is not one word about inoculations, not one word about preventive medicine; worst of all, there is not one word about anaesthetics. He is careful to say we cannot silence him by saying that these horrors were not done in England; he "is dealing with vivisection internationally." We hope that we have found a very easy way to silence him; we have shown that he has not even attempted to study his subject. Let him study it in all patience, honesty, and humility for six months. At the end of that period let him acknowledge his errors, and commit to the flames the remaining copies of this most unhappy pamphlet.

MENTALLY DEFICIENT CHILDREN. By G. E. SHUTTLEWORTH, B.A., M.D. London: H. K. Lewis. 1895. (Crown 8vo, pp. 140. 4s.)

THE author does not profess in this book to bring forward anything new, but to collect various papers which he has previously published in medical journals and proceedings of societies. A historical retrospect is given of the subject, from which we learn that about fifty years ago attempts were first made to train the mentally deficient child, and that Seguin is to be considered as the pioneer in the work. Some illustrative cases of children of this class are related, and reference is made to the work which Dr. Warner has done in examining 100,000 children belonging to various schools. Very valuable material has been collected, and this, it appears, will soon be available to the profession and the public when the report of the Committee on the Mental and Physical Condition of Children is issued. The establishment of schools for special instruction by the London School Board is alluded to; and it is useful to know that there are now seventeen centres, at which 800 children attend for special instruction and training. Pathology obtains only scanty notice, but the author refers those who are interested in the subject to books in which information respecting it can be obtained. Cases are divided into congenital and non-congenital, and a description is given of the various forms of mental deficiency which are met with in institutions which receive these children for treatment. The etiology of the

subject is shortly noticed, but the diagnosis and prognosis are fully considered. The treatment occupies four chapters of the book, and some illustrations are given of the apparatus employed in training the special senses of these cases.

The author is of opinion that more institutions for the education and training of juvenile imbeciles should be erected, and additional industrial homes for feeble-minded young women should be provided. A list of the public and private training institutions, and of School Board classes where special instruction is given, is found at the end of the book.

NOTES ON BOOKS.

The Art of Breathing as applied to Physical Development: with Respiratory Exercises for both Children and Adults. By A. L. HOFER-DIXON, Surgeon-Captain, A.M.S. (London: Gale and Polden. 1875. Fcap. 8vo, pp. 30. 2s. 6d.)—This little book will fulfil a useful purpose if it teaches soldiers, athletes, and others the necessity of a correct manner of breathing; for though the act of breathing is performed automatically, there is no doubt that the exercise of the will can play an important part in correcting the *modus operandi* of the respiratory act should it require correction. Abdominal breathing is very properly regarded as that which gives the best results, and any error of dress which interferes with the movements of the diaphragm should be removed. The exercises with which the pamphlet concludes appear well adapted for the end they have in view.

Official Drill Manual for the Members of the St. John Ambulance Brigade. Compiled by REGINALD SLEMAN, M.A., and W. J. CHURCH BRASIER. (London: St. John Ambulance Association. Demy 32mo, pp. 74; 6 illustrations. 6d.)—This little book is, as stated in the preface, a simple guide for the use of those engaged in teaching the St. John Ambulance Brigade the rudiments of drill and discipline. It is on the lines of the army regulations, and the directions given are clear and concise, and such as can be understood by those not accustomed to military drill, the descriptions being accompanied by explanatory diagrams. In the latter part of the book will be found some very useful information about the various methods of moving the sick and injured, matters which are sometimes lightly regarded, but on the proper performance of which the immediate comfort, and not infrequently the ultimate result to the patient, largely depends.

The Annual Report of the Mansion House Council on the Dwellings of the Poor. (London: Cassell and Company. 1895. Demy 8vo, pp. 88. 1s.)—This report shows how much requires to be done to maintain the effective working of the various laws and regulations which have been made to ensure the sanitary condition of the dwellings of the poorer classes. Notwithstanding the large powers possessed by local authorities, from the very constitution of many of the vestries there is a tendency to allow these powers to remain in abeyance, and it has often been found advantageous for the Council not only to make its own independent inspections, but for it to step in and take the matter of putting the law in force into its own hands. Attention is drawn to the urgent necessity which exists for some uniform standard of sanitation throughout the metropolis, for a study of the cases of insanitation which are brought before the magistrates and of the decisions which have been given upon them, shows how often it happens that what one magistrate upholds another will condemn. An evil of perhaps almost equal importance is the practice, to which attention is drawn, of medical officers of health stepping out of their own districts to give evidence in favour of bad property in other metropolitan areas, such evidence being in direct conflict with that of the district medical officer. This is a question of ethics worthy of careful consideration. The report contains four illustrations representing "cottage homes" in London, which have been projected and are being worked by Miss Octavia Hill and her band of devoted helpers. Such buildings are to be highly commended, and are incomparably superior to the barrack dwellings which are becoming so common.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DENTISTRY AND THE
ALLIED SCIENCES.

HYGIENIC TOWELETTES.

We have received from the Sanitary Wood Wool Company samples of their improved towelettes, for which it is claimed that they are turned out with greater softness and absorbing power than hitherto. These excellent towelettes might well replace the old-fashioned linen diapers, as they can be purchased at 1s. a dozen, which is about the cost of washing the ordinary diaper now used.

TEA, COFFEE, AND COCOA MEASURE.

This invention is made as a small bell-shaped cup, with divisional markings from one to four teaspoonsful. An article such as this is much needed for the purpose of exactness to prevent these beverages being made too strong, and thus causing them to be injurious to the health and distasteful to the palate, or of being made so weak by insufficient quantity as to be not worth drinking. The measure is a great improvement on the rough and ready way now in vogue of measuring by various size teaspoons. This useful article is to be obtained at the Army and Navy Stores, Victoria Street, Westminster.

REPORT ON THE SANITARY CONDITION OF
WINDSOR.

By BAILEY DENTON, M.Inst.C.E.

IN accordance with instructions from the Editor of the *BRITISH MEDICAL JOURNAL*, I visited Windsor on October 8th and 9th with a view to report upon its sanitary and general condition.

Before describing in detail things as they are, I desire to state that in the years 1885 and 1886 considerable stir was made in the town with regard to the insanitary condition of its low-lying slums, and that public attention was drawn to the matter in the press. As a result of this publicity a deputation from the Town Council, with the borough member, waited upon Mr. Ritchie, M.P., the then President of the Local Government Board, on September 14th, 1886, and, after complaining of certain statements which had been publicly made concerning the sanitary condition of the Royal Borough, requested him to institute an inquiry on the subject through his inspectors, and promised to abide by their recommendations. As a result, Dr. Hubert Airy and Mr. Arnold Taylor, both of the Local Government Board, went down to Windsor in the October of that year to examine into the whole question, and on January 17th, 1887, issued a report.

This report, after stating that the population of the town—including the garrison of household troops, infantry and cavalry—amounted to about 12,000, acknowledged in most plain language that in the lower districts, where all the poorer dwellings erected in recent years are built, and which are situated on the alluvial plain that stretches at the foot of the western slopes of the Castle, as well as in one quarter of the older portion of the town, periodical floods occurred, with the result not only that great temporary inconvenience was caused, but that a most unwholesome state of things ensued.

The inspectors examined the numerous courts and alleys between the river and the main street, giving as a result their opinion that their condition was "at all pitiable bad." The following places came under their immediate notice, and are described in detail in the report: Bier Lane, Garden Court, Collins's Buildings, South Place, Charles Place, Keppel Row, and Keppel Court.

After passing in review these unhealthy and overcrowded districts, they next called attention to the fact that in many instances the house drains throughout the town were ill-laid and unventilated. That the waterclosets were frequently un-

flushed. That there existed no means of burning the house refuse, and that, as a result, it all had to be carted away to a field about a mile from the centre of the town, where it was used to fill up hollows, and created an offensive smell. That there was no hospital for the isolation of infectious diseases. And, lastly, that the sanitary staff of the borough was insufficient, inasmuch as the borough surveyor not only acted in that capacity, but was inspector of common lodging houses, weights and measures, petroleum, and canal boats.

The inspectors after expressing an opinion that some allowance should be made for the difficulties besetting sanitary authorities in their endeavours to amend the faulty state of things existing in all old towns like Windsor, and which have been inherited from bygone centuries, finally recommended: (1) That the sanitary defects existing in the low-lying slums should be remedied under the powers given to the Borough Council under the Artisans' and Labourers' Dwellings Improvements Acts, 1875-82; (2) that they should appoint a separate inspector of nuisances; (3) that they should provide a hospital for the treatment of infectious diseases; and (4) that they should build a furnace for the destruction of house refuse.

It may be presumed that Mr. Ritchie, on receipt of this report, was not content to leave things as they were, for he instructed the same inspectors to revisit Windsor and again report to him, which they did on November 20th, 1889; and the contents of their second report, which is under date January 23rd, 1890, may be thus fairly summarised.

They found that a few of the most disreputable houses in several of the numerous courts had been pulled down, and that there was generally an increased watercloset accommodation; but that practically the courts and slums were only in a slightly better condition than on their previous inspection, and that certainly the Town Council had taken no notice of their advice that they, as the Urban Sanitary Authority, should make use of their legal rights, and remove most, if not all, of the evils complained of. They observed that a separate nuisance inspector had been appointed, and therefore expressed the hope that there would be improvement with regard to the slums in the immediate future. They, however, again drew the attention of the Local Government Board to the fact that, although nearly three years had elapsed since their first report, there was still no hospital for the isolation of infectious diseases; and that no refuse destructor had been built. In their closing paragraphs they announced that the Mayor had informed them that it was in contemplation to construct a new riverside road and promenade, which would not only greatly beautify the town, but would remove some of the insanitary courts abutting on River Street.

I now come to the condition of the town in October, 1893. It will, I think, be generally conceded that as a Royal Borough, to which in consequence visitors and foreigners constantly flock, the condition of Windsor should be, if anything, better than that of other towns, and certainly that within its limits there should be no evidence of continued and needless neglect.

I propose to treat the various points brought under my notice under the following heads:

There are no public baths and wash-houses. This will hardly be credited when the large number of resident poor is taken into consideration, who must find it most difficult, especially in times of flood and frost, to have recourse to any methods of cleanliness.

No hospital for the isolation of infectious diseases has been built, although the provision of one was strongly recommended in both reports of the Local Government Board in 1887 and 1890.

Slaughterhouses are still in use in the principal thoroughfares of the town, so that sheep and cattle can be seen being led to the slaughter from the very residence of the Sovereign.

No new road and river-side promenade has been made, as foreshadowed by the Mayor in 1890. Why this long needed improvement has not been carried out it is difficult to say, but it is rumoured that some of the Corporation are afraid that a handsome new street, adjacent to the river, would remove the business of the town away from High Street and

Thames Street, where the principal old-established shops are situated.

The condition of the streets is lamentable. The surface of the granite cubes—for example, in Peaseod Street—is needlessly uneven and injurious to carriage traffic, whilst all the main thoroughfares are badly kerbed and channelled. The macadamised roads also are equally neglected, and after rain pools of water remain on them for days, thus creating an unnecessarily humid atmosphere. Grass is allowed to grow in several of the roads—for example, round Trinity Church—in a way which I have never seen equalled in any English town of a similar size. The pavements likewise, even round the Castle, are in a disgraceful condition.

Royal Windsor is approached from the river above Windsor Bridge either by River Street or by Goswell Road. The traveller, on landing from his boat at River Street, is immediately confronted on his left by a huge wooden dustbin, full of filth, measuring 6 ft 6 ins. by 3 ft., and on his right by tumbledown houses let in tenements, whilst in front of him is a steep narrow street ending in a slaughter-house, immediately under the Castle walls. Should he elect to reach the town by Goswell Road he will land near about twelve heaps of rubbish and brick dust. Beyond this his route lies along a dirty road, with inferior cottages on the left, until he reaches the Great Western railway viaduct, where, should he desire to pass by a near way to the booking office, he will go through an arch, the roadway under which is covered with manure and rubbish. Arrived at the top of the hill, or, in other words, at the Great Western station, he will stand between two approach (or rather reproach) roads, the condition and width of which would be a disgrace to any important town in the country.

I will now refer to the appearance and condition of the houses.

As to those inhabited by the wealthier class, it is obvious that, as a rule, the outside sanitary arrangements are defective. The soil pipes are mostly ill-ventilated, whilst the rain-water pipes in many instances are leaky; in fact I do not believe that there are many houses in the borough which would successfully stand a modern sanitary test. A general appearance of neglect predominates throughout, and in one road which I could name there are sixteen empty houses within a distance of 800 yards. On inspecting one, which was provided with a large brick dustbin close to the lawn in the back garden, I was told by the caretaker that, though it had been built nineteen years, it had only been inhabited for three; he added that the reason was that the smells of the adjacent open ditch were intolerable in summertime. Why the Town Council have not covered this ditch over he did not know.

As to the condition of the poorer dwellings in the low-lying districts, considering the advance made in sanitary science during the last ten years, they practically remain as they were. Amongst the most noted slums which I inspected were South Place, Collins's Buildings, Haines Court, Love Lane, and Garden Court. In South Place most of the houses contain only two small rooms, with one water-closet situated outside and used jointly by two dwellings. These water-closets are in nearly every instance worn out and in a filthy condition. They are supplied with water (an improvement on 1886) from a waste-preventing cistern above them, which is in every instance unprotected from frost, the consequence being that during the cold weather, when a good flush is essentially necessary, no water can possibly be obtained. There are a few taps off the public water mains in the back yards from which the people can obtain water, except in lengthened frosts, but the public supply is in no case carried into the houses. There is no sink accommodation beyond one or two outside gulleys in the back yard common to the whole court; whilst the inhabitants of the houses on the south side of the court, who have no backyards of their own, are obliged still to cross the road to the yard at the back of the houses on the north side in order to use the water-closets.

In Collins's Buildings, which are four-roomed houses, let at rentals of 3s. 6d. per week, the flood last November rose to 3 feet above the ground floor level, and as a consequence signs of decay and damp are still everywhere apparent. The water-closets, gulleys, and water supply are practically in the same position and condition as in South Place. The same remarks

apply to Haines Court and Garden Court. The worst and filthiest slum of all, however, is Wellington Square, Love Lane, which is surrounded by two- and four-roomed houses, with an unpaved surface in the centre covered with filth, with a few water-closets and old washhouses on either side falling to pieces. In all the courts are large worn-out dustbins, which are only emptied once a week, and which at times, between the periods of removal, must emit most noxious odours.

Is Windsor worse than other towns? My reply, after a certain amount of experience, is decidedly Yes. What, then, are some of the remedies? If in 1886 the Local Government Board inspectors pointed out that there were in existence Acts of Parliament which would enable the Town Council to do away with the above disgraceful slums, still more so are there now, after the passing of the Housing of the Working Classes Act, 1890, which provides that local authorities may carry out improvement schemes for the rearrangement and reconstruction of the streets and houses within their jurisdiction. There is therefore ample legal machinery at command if only it is set in motion. Each house should be provided with a separate water-closet, and an indoor sink and water tap. The huge and nauseous dustbins should be done away with, and small galvanised iron dustbins substituted, the contents of which should be frequently removed and burnt in a destructor. An isolation hospital and public baths should be immediately built. The slaughterhouses should be removed to less objectionable sites. The sanitation of the houses of the wealthier classes should be more looked after, and all necessary modern requirements where possible insisted on; whilst the roads should be properly paved and channelled; and last, though not least, the approaches from the river should be improved.

It will probably be asked whether the annual death-rate in Windsor is so excessive as to justify this all-round censure. My answer to such a question is that the details of a death-rate are entirely outside my province. There are, however, many things in this life much more to be feared than death, amongst which may be mentioned uncleanness and degrading vice, and neither of these evils runs much chance of being eradicated at Windsor if things are allowed to remain as they now are in the Royal Borough. No good will be done by blaming officials, so long as they remain servants of the local authority and not of the State, and who therefore frequently are afraid to speak their mind. On the contrary, the remedy rests entirely with the Borough Council, and it is for them to act without delay.

FACTORY AND WORKSHOP INSPECTION.

THE report of the Chief Inspector of Factories and Workshops for 1894 reached our hands a few weeks since. It forms a considerable volume of over 500 pages, and contains a mass of facts respecting our great industries and also our smaller ones, and workshops. It tells of perpetual industrial progress, and affords numerous particulars which show the condition of those engaged in them, and makes besides many suggestions for improvements.

The extension of the Factory Acts, and particularly the passing into law of the Workshops Bill, have immensely enlarged the business of the Factory Department of the Home Office. The report before us proves the necessity for, and the wisdom of the extension brought about. In fact, it goes much further than this, for it brings to light the need of still further extension, of the existence of legislative omissions and anomalies to be remedied, the necessity for amendment and revision, and generally of an improved administrative organisation.

The institution of a class of lady inspectors by the former Home Secretary, Mr. Asquith, has proved a success, as indicated by the work done. The ladies exhibit great interest and energy in their duties, not devoid of the ambition to have additional work entrusted to them, and to render their position still more important than it is.

As a matter of courtesy doubtless the chief inspector, acting on the maxim of "ladies first," accords to the reports of the lady inspectors the first place. The call for women inspectors was made in the interests of female workers, who, presumably, were imagined to be reticent in making complaints or in meeting the inquisitiveness of male officers.

Those feminine weaknesses are not, in our experience, very pronounced; and, if they do exist, factory and workshop hands must have them in a higher degree than women of other classes; for we must remember that inspectors have not to pry into the diseases of women or to report upon them; and if such interrogations are to be made it should be the business of some authorised medical men, or, for that much, "medical women," to make them, and to do this would imply a considerable extension of the Factory Act in regard to its purposes.

At the same time it may be admitted that the sudden inroad of one of the ruder sex into a milliner's or a dressmaker's workroom may cause a flutter and disturb the prevailing quiet serenity of the occupants; and that also in those cases where the workshop occupier has cause for hiding some of the "young ladies" from the eye of an inspector, a female officer may more appropriately search the apartments. Moreover, it might possibly be held by some that females will best know the female character and be more capable of bringing to light the subtleties and evasions which are not confined to male persons and might be unsuspected by them.

Again, if we admit their own estimate of fitness for the employment, lady inspectors are fully qualified to perform its duties in all respects and under all circumstances—difference of sex forming no obstacle. This persuasion on their part shows itself by their readiness to engage in sanitary matters of all sorts, and to investigate the effects on health of industrial processes; indeed, in all such matters, to undertake duties usually assigned to the action and supervision of medical officers of health.

In these pretensions they unfortunately have received encouragement from the chief inspector, who has entrusted to them the duty of noting the ventilation and the warming of places they visit; of inquiring into the effects of the many manufacturing processes on health, including those in which lead is employed; and generally of supervising and reporting upon the due observance of special rules made for the conducting of those trades classed as dangerous to health.

Individuals uninitiated in official notions respecting the fitness of employees for particular duties would probably fancy that all such lines of inquiry appertain rightly to those who have been specially trained to conduct them, and that with respect to some employments males are more eligible than females in the work of inspection—in a word, would conclude that sanitary functions at large should be exercised by sanitary officers. This principle we have always contended for, and consequently treated it as a blemish in the factory laws that sanitary provisions are relegated to non-professional though most worthy gentlemen to carry out.

It is the more anomalous when we look at the laws relating to the general health of the population: these demand special instruction in sanitary science, and evidence furnished by examinations that medical officers of health possess ample knowledge of the whole range of subjects included in the science of sanitation. These qualifications are increasingly called for as the importance of sanitary science becomes better understood; yet when efficient sanitation is required in the health interests of workers in factories and shops any lady or gentleman is officially accounted as qualified for the undertaking. The question of special education and qualification is not raised. To any logical and thinking mind this state of things is inexplicable, and the more so as in the case of manufactories and workshops causes of illness are not limited to those common to all habitations but to a host of pathological conditions attaching to the work carried on and to the materials employed—that is to say, to a far wider set of circumstances affecting health and life. Who can fail to see this grave anomaly in legislation, and the necessity of assimilating the sanitary regulations in the health of towns and in the factory laws.

The reports sent in by both lady inspectors and the old staff to the Home Office concur to show the inadequacy of the administrative machinery in existence to compass the objects of the Factory and Workshops Act; and it is equally clear that the remedy wanted is to increase the medical agency.

But we must not dismiss from view so cavalierly the work collected by the lady inspectors. It deserves more considera-

tion and appreciation at our hands, for their reports prove that, in the case of workshops especially, they have accomplished much excellent sanitary work. This is true in particular with regard to dressmakers' and milliners' shops, to numerous small tailoring establishments, and to many small handicrafts pursued in dense and poor districts, of which the East End of London supplies the most examples. In many such places the labour of women and girls is most in request, and it is a fair inference that female inspectors may more readily and thoroughly reach such workers than those of the male sex.

Their quick observation and their ready realisation of the wants of their toiling sisters furnish additional arguments for their employment where female labour abounds. And accordingly they have been enabled in their reports to make some useful suggestions and to point out, among other things, the abuse of exceptional permission to work at times beyond the legal period; the evil custom of locking the women in their workrooms, of inflicting illegal fines, and making deductions from wages earned to pay for articles supplied. The suggestion that no young person under the age of 15 shall work overtime is good, and derives sanction from a similar provision in the industrial codes of Germany and Scandinavia. But this suggestion is less drastic than that advocated by some of the male inspectors, who would altogether abolish overtime.

Another subject most urgently insisted on is the necessity of providing a water-closet for each sex where men and women are employed in the same building. That this provision has been so widely neglected, notwithstanding its patent necessity in the interest of cleanliness, decency, and morality, reflects discredit on all who are vested by law with authority to secure its observance.

We observe that one new inquiry has been conducted by Dr. Arlidge since the issue of the preceding general report of the chief inspector—namely, on the effects of naphtha as used in rubber works on the health of the employed. The general conclusion is that though the vapour be objectionable, it causes no actual injury to those who breathe it.

But we hasten to conclude this notice of the official report, though we must not fail to remark that there are several other topics contained in it which well deserve attention, but are little likely to get it, being as good as buried in a Parliamentary Blue Book.

THE RUSSIAN JENNER CELEBRATION.

WE have received from our St. Petersburg correspondent the following further particulars¹ relating to the Russian National Health Society:

The Russian National Health Society, which is under the presidency of His Imperial Highness the Grand Duke Paul Alexandrovitch (the youngest brother of the late Emperor) determined last spring to make arrangements for celebrating the centenary of the introduction of vaccination in a becoming manner. The Imperial rescript permitting them to do so was signed on April 27th (old style). The Society then selected May 2nd (1426) 1896 as the day on which the centenary should be observed, this being, according to the circular issued by the Society, the date on which—in 1796—Jenner made the "first scientific experiment on the subject of vaccination." They further announced that they would celebrate the occasion in the following manner: (1) By offering four prizes for the best literary work upon vaccination; (2) by collecting and publishing (with the co-operation of the Government, the zemstvos,² municipalities, learned societies, and private individuals) materials for a history of the practice of vaccination in Russia, together with a brief account of the practice in Western Europe; (3) to publish in Russian a translation of Jenner's works, with his portrait, biography, and drawings of small-pox; (4) to hold an exhibition of objects relating to vaccination; (5) to call a special meeting of the Society for the day appointed for the anniversary.

A further public notice was issued, containing the following details as to the prizes offered:—Works sent in for competition may be: 1. Such as relate to the general questions of small-pox and vaccination for instance, (a) handbooks of vac-

¹ BRITISH MEDICAL JOURNAL, August 18th, 1895, p. 291.

² Zemstvo=local governing bodies.

nation; (b) historical, medico-geographical, or medico-statistical essays on small pox and vaccination; (c) clinical, pathological, bacteriological, chemical, or other investigations; or (d) works for the general public on the utility of vaccination.

II. Such as relate to the *technique* of vaccination; for instance, (a) essays on improved methods of preparing lymph, and particularly on the best modes of preserving and transmitting it; (b) proposals for new or improved instruments and other apparatus required in vaccinating human beings and animals; (c) suggestions for a model vaccination institute.

The above programme is not intended to limit authors to any one of the headings mentioned; they may combine any of them, and also deal with other aspects of the subject not mentioned above.

Essays for competition may be in the Russian, French, German, or English language; they may be in manuscript or in print, but in the second case they must not have been published before May 2nd (14th), 1894. They must be sent in not later than March 2nd (14th), 1896, addressed to the Council of the Russian National Health Society, 15, Dmitrofski Pereulok, St. Petersburg.

The essays will be judged by a special committee of the Society, and the prize winners announced on the day of the centenary. Essays may be sent in signed by the author's name, or by a *nom de plume*; in the second case the author's real name must be sent in a closed envelope, bearing the *nom de plume* outside.

Four prizes are offered: the first will be the Society's gold medal and 1,000 roubles (about 100 guineas); the second a gold medal; the third a smaller gold medal, and the fourth a silver medal. The names of the prize winners will be published in the papers.

The Society have also invited all institutions, medical men, and private individuals to co-operate with it in making the centenary a success; particularly in furnishing it with information, or by lending it objects of interest in connection with the history and practice of vaccination. All such aid will be gratefully acknowledged, and the names of persons who so co-operate with the Society will be published in the centenary report. Information or objects of interest should be sent to the Society, at the above address, if possible not later than December of the present year.

LITERARY NOTES.

PROFESSOR ANTONIO DE GORDON Y DE ACOSTA has published a work entitled *Medicina Indigena de Cuba*, in which he gives a mass of interesting information as to the medicine of the natives of Cuba at the time of the discovery of America. That they were not entirely destitute of elementary notions of hygiene is shown by the fact that the use of the bath was general and frequent among them, that they abstained from sexual intercourse during menstruation, and that isolation of sufferers from diseases believed to be contagious was enjoined. Their habit of staining their skin with vegetable colouring matters mixed with fatty substances was probably, in part at least, adopted as a protection against the stings of insects. Their food was chiefly vegetable, but they also ate largely of fish: the flesh of wild animals, birds, lizards, larvae, and ant eggs also entered into their dietary. The dead were disposed of by cremation, by burial, and by mummification. They had some notions as to diseases of the respiratory, digestive, and genito-urinary apparatus, worms, rheumatism, fevers, nervous diseases, and intoxication by the abuse of snuff. They appear to have been very subject to skin diseases, and the descriptions of the Conquistadores, though vague, suggest that neither syphilis nor leprosy was unknown to the aboriginal Cubans. Their materia medica included certain purgative substances; they had a kind of castor oil which was used in cases of colic and dropsy, and also as a preventive of skin diseases and as a cure for deafness; *hoaxacan* (guaiacum) was used for the treatment of glands and anæmia; tobacco was applied to wounds and was employed in the treatment of asthma, toothache, and other diseases; *sassafras* was given in fevers, and pineapple was used as a remedy for stomachache. A large number of plants which still hold a place in scientific therapeutics were also used. The medicine men were priests as well as physicians, and when a chief died his doctors were

expected to kill themselves in order to continue their attendance in the other world. Probably there was not a very keen competition for the dignity of court physician among the Cuban faculty in those days.

Surgeon-Major John Smyth, I.M.S., writes from Madras to call attention to "a literary error" in the article on "Diseases of the Gall Bladder" in *Quain's Dictionary of Medicine*, where dropsy of the gall bladder at a certain stage of its existence is called *hydrops cystidis felleæ*. Dr. Smyth says:

Greek words like *cystis*, which have the genitive case, when Latinised have the same form both for genitive and nominative. Gray gives the word properly when describing the fossa for the gall bladder—*fossa cystidis felleæ*.

Doubtless the editors will feel grateful to Dr. Smyth for his concern about their grammatical orthodoxy. When they correct the little slip, however, we venture to suggest that they might with advantage substitute *vesicula felleæ* for *cystidis felleæ*. "Cystis" is, strictly speaking, not Latin at all in the sense of "bladder," and the plea of necessity cannot be urged on its behalf. *Vesicula felleæ* is given as the Latin equivalent of gall bladder in the *Nomenclature of Diseases* of the Royal College of Physicians.

In the *China Medical Missionary Journal* for June, Dr. J. Dudgeon gives an interesting account, with illustrations taken from the Chinese *Golden Mirror of Medicine*, of various manual methods for the treatment of fractures, injuries to sinews, dislocations, etc. These are the *moh* or feeling method, the *chiek* or uniting method, the *tsuan* or supporting method, the *et* or elevating method, the *annoh* or pressing and rubbing method, and the *tsu-na* or the method of pushing and taking hold of (so as to place the bone in position). These methods may require to be supplemented by apparatus. Ten different methods are described by which the broken may be joined, the slanting made straight, the elevated made even, the depressed raised, the dangerous made benign and peaceful, the severe made light; the administration of medicine and a nourishing diet are enjoined as part of the treatment. As a specimen we may take the method of suspension reinforced by the use of piles of bricks. The patient grasps with both hands a rope slung transversely above his head; three bricks piled one upon another are placed under each foot. This is to cure injury of the thorax, abdomen, axillæ, and ribs, no matter how caused. The chest has become depressed and must be elevated. The patient first takes hold of the ropes, standing on the bricks, with his loins fixed. Then one brick is removed from each side, the patient straightening his body and fixing the thorax. This is to be repeated three times, when the feet will have reached the ground and the air will have circulated and the superfluous air have been dissipated; the depressed will have become elevated, the bent will have become straight. Then the patient must be enveloped in a bamboo screen—which in the illustration looks not unlike a corset but appears to be adaptable to any part—and eight broad bandages must be applied, and "everything is to be made proper and suitable." He then ought to recline on his back, and, when sleeping, ought not to lie either face downwards or on one side, and a pillow ought to be placed under the loins, all movements to the right or left being forbidden.

The first two volumes of the *System of Medicine*, edited by Professor Clifford Allbutt, are now in the press, and Messrs. Macmillan hope to be able to issue them shortly. This first portion of the *System* will consist of Prolegomena: on Inflammation by Professor Adams; on Fever by Professor Burdon Sanderson; on Therapeutics by Professor Leech, Dr. Hermann Weber, Dr. Lewis Jones, and others; on General Pathology by Dr. Mott and Messrs. Shattock and Bullock; and on the Pathology of Infection by Dr. Kanthack. The section dealing with the Infectious Diseases is also in an advanced state.

Messrs. Rivington, Percival, and Co. have in the press, and will issue shortly, a work of a somewhat novel character by Dr. C. J. Cullingworth, of St. Thomas's Hospital, entitled *Clinical Illustrations of the Diseases of the Fallopian Tubes and of Tubal Gestation*. The basis of the work is a series of drawings from specimens removed by operation. Each specimen is accompanied not only by a description, but by a clinical history of the case. The volume will contain fourteen plates illustrating all the commoner and not a few of the less common diseases of the parts.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, OCTOBER 26TH, 1895.

THE HARVEIAN ORATION.

THE place of Harveian Orator could not have been more admirably filled than by the Senior Physician of St. Bartholomew's Hospital. The Orator wisely decided not to handle again those passages in the life, work, and records of Harvey which have been exhaustively treated by Sir James Paget and others of his predecessors. After a tribute to the honoured name of Parkes—happily coupled on this occasion with a reference to the generous foundation of his friend still preserved to us, Dr. Hermann Weber—Dr. Church (as will be seen from the text of his oration published in another column) proceeded to an examination of the relative places in science and in philosophy of Aristotle, of Bacon, and of Harvey. His words were not those of current opinion, but of a deeper and more instructed judgment. Thus we are tempted to consider with more than usual care these parts of his oration, and we are stimulated to that more serious discussion and criticism of his statements which, even when we differ from them, will appear, we trust, to testify only to their merits.

Dr. Church is on strong ground when he sets forth Aristotle's prodigious achievements as a biologist. Not only was this extraordinary man the founder of biology—or, as we should prefer to say, of natural history—but he also built largely upon his own foundation; herein he showed himself a far abler master of method than Bacon. Not only in the collection of a vast mass of information—which, as has been well said, testifies as much to the alert intelligence of those of his contemporaries who were able to supply him with such valuable information as to the inexhaustible energy and thirst for knowledge in the master himself—but also in his generalisations from these facts, his labours were relatively greater and more successful than those of any other scientific man of any age. We have only to refer to Aristotle's personal observations on embryology to convince ourselves of his mighty and fertile intellect.

Bacon, on the other—superb in wit and in power of philosophic statement—added little which, apart from the way of putting it, was positively original in itself; and when he came to illustrate his own method, or rather that of Aristotle, in practice he showed himself far the inferior of his great master and of Harvey. This was, no doubt, Harvey's meaning in his well-known epigram that Bacon wrote about Nature like a Lord Chancellor. The author of the *Opus Majus*, indeed, has more claim to our regard as

a man of positive scientific intellect than his eminent namesake and successor.

It is habitual with us to regard Bacon as the giant who delivered us from the "dead hand" of the ancients—Plato and Aristotle and Galen—whose works had become a bondage to later generations. But Dr. Church was strictly justified when he spoke of the large debt which Bacon owed to Aristotle. In their monumental edition of Bacon's works Messrs. Ellis and Spedding have proved that, magnificently as Bacon translated his matter, he owed almost the whole of it—save its errors—to his great forerunners. Bacon, indeed, was not only out of the track of those fertile scientific conceptions and observations which arose in his own day; not only was his own method never deliberately applied to the investigation of natural phenomena, but, as Mr. Ellis has shown, he also misconceived the problem to be solved. Mr. Benn has acutely said that there is no such thing as a *a priori* speculation; for, apart from observation, the boldest intellect can do no more than rearrange the materials or thoughts of his predecessors. "Still," he adds, "if ever any system was constructed *a priori* the *Instauratio Magna* was."¹ Bacon, no doubt, thought that an instrument might be found for extracting the virtues out of Nature as, after their fashion, the alchemists sought to do. On the other hand, he followed Aristotle in some of his least justifiable distinctions between matter and "form."

Dr. Church pointed out that, although Harvey, when at Padua, must have been in the very midst of the bitter conflicts of the Aristotelians and their opponents; yet that he preserved a mind well balanced amid them all, and in all his writings invariably paid the greatest respect to Aristotle. Again, the Orator well said that Bacon was by no means the first or even the chief deliverer from the pseudo-Aristotelian bondage—a subject which neither he nor we can fully enter upon, though we may suggest that the translation of Aristotle by St. Thomas Aquinas first led to the more rational use of his authority; he reminds us that Aubrey also speaks of Harvey as esteeming Bacon rather for his wit and style than for his philosophy.

On the other hand, in his remarks upon "final causes," the Orator seems to fall into some confusion. In speaking of Aristotle's habit of specifying a final cause for every part of the body as one which led him to error, and gave rise to Bacon's well-known gibe that the study of final causes was as sterile as a virgin consecrated to a god, Dr. Church tells us that herein Bacon was wrong again. He alleges against him the evidence of Harvey himself, who says that his study of the valves of the veins led him towards the discovery of the circulation of the blood, and "that so provident a cause as Nature had not placed so many valves without design." Whether final causes are to be considered at all is a question which must not be discussed here; but we must point out that the detection of adaptations is a widely different thing from the discovery or attribution of final causes, in the proper sense of the term, as ultimate purposes. In Aristotle's mind (as, perhaps, more or less in the minds of all philosophers before evolutionary conceptions had their recent more definite beginnings) an organism, like any other natural aggregate, was supposed, by whatever cause, to have come into being complete, and it was regarded

¹ *Quoted in the Preface, 1869, vol. ii, p. 513.*

mainly from a statical point of view; thus the adaptations in such an aggregate may seem to indicate immediate design. But from the moment that an organism is supposed to have been developed gradually by an infinite series of protective adaptations, and to have gained these adaptations by a process of elimination, then, unless some perverse person were to say that the valves of the veins, for instance, were there by accident, we should assume that these related functions and parts merely present the facts of existence from a dynamical point of view; that, in a word, these correlations are but a mode of saying that the animal exists. To admire the ermine as a little beast created for the purposes of the dignity of the law is to regard final causes; but to admire its adaptations, internal and external, in a state of Nature is a biological analysis, and not a study of final causes. To say that our predecessors did not always distinguish the means of becoming from these ultimate uses is true, but the distinction is a real one.

What Aristotle did for biology and the great anatomists of the sixteenth century for their study, Harvey did for physiology. This the Orator aptly illustrated from Harvey's own works. In an admirably constructed address he then went on by an easy transition to the regeneration of clinical medicine by Sydenham, whose immediate debt to Harvey is not easy to discover and was probably indirect.

Finally, in a weighty peroration Dr. Church invited us to consider whether "the very brilliancy of recent discoveries and the vast increase in our knowledge may for a time react injuriously on the art of medicine." This is a very anxious inquiry for those who are driven year by year to add more and more to the course of medical training. May we not be positively encumbered in the application of our science by the overwhelming accumulation of facts?

We take a more hopeful view of the immediate future; the qualities of mind and sense which are cultivated in the laboratory will bear fruit in the field of clinics, as indeed we may see to-day; never was clinical observation more accurate and more fruitful than it now is, in spite of the concurrence of the laboratory. The wider our explanatory formulæ, the more readily will be cultivated in our students that scientific attitude of mind which is a better equipment for the duties of life than a wilderness of facts learned by rote.

WAR OFFICE REORGANISATION AND THE ARMY MEDICAL DEPARTMENT.

ALL sorts of rumours are already in circulation on possible changes in army medical administration under a reorganised War Office. We may safely believe that nothing whatever is yet authoritatively known of such changes—good, bad, or indifferent. The question has probably not even been approached, much less discussed; but when the attitude of the new Commander-in-Chief to the medical service in days gone by is considered, we cannot wonder that even premature speculation becomes rife as to his possible policy towards it in the near future. It is apparently foreseen that, although Lord Wolseley is to be only one of five in a deliberative Board, yet his high position and remarkable powers of initiative will practically make his opinion paramount in questions of administration. But whether he has a free hand or not, in his new office he will undoubtedly

wield far greater power than he has hitherto possessed; although it may be doubtful whether, under the shield of a Board, his direct responsibility will be, as it ought—correspondingly increased.

We have faith that his wide experience and strong common sense will impart circumspection in dealing with every branch of the service, but we may remind him that caution will have to be superlatively necessary in dealing with the medical department. He may, indeed, turn out its regenerator, and thus falsify present doubts and fears; but a single and simple false move might prove disastrous enough. We would suggest that ill-advised changes are best to be obviated by the military authorities frankly taking into their confidence the wisest heads in the department itself, and among the medical profession at large.

We do not yet know how medical matters are to be discussed by the new Boards and Councils; but, in the various accounts of the proposed War Office reorganisation we have seen, it is with surprise and misgiving we observe that the medical service and army sanitation have never been so much as mentioned. It can hardly be that in future such matters are to be held secondary and unimportant in the war councils of the nation; least of all in an Imperial Empire like ours, with soldiers living and fighting under every climate on the globe. The exact position and representation of the medical department in the new War Office Boards is so important that it must be inquired into directly Parliament meets; it is with this view that we call early attention to the question, in order that its true bearings may be ascertained by preliminary discussion.

Lord Wolseley—for we cannot speak of an impersonal Board—now has it in his power to do great good, or to work indefinite harm, to the army medical service; but the times are ticklish, for those who have the best means of judging see clearly that another crisis in its fortunes is steadily if not rapidly approaching. The best evidence of that is its growing unpopularity in the medical schools, through which there is already not only a qualitative but a numerical deficiency of candidates for commissions; in fact, it cannot be denied there are already unfilled vacancies, and the gaps in the ranks a year hence may be very serious. In one sense, therefore, the new Commander-in-Chief and his colleagues have a splendid opportunity of putting the entire army medical service on a fresh and better footing; but, in another, they must recognise that their powers are limited in certain directions; for they must needs consult the views and feelings of the medical officers themselves; otherwise, if the War Office attempt to ride roughshod over the department, they will only scare away candidates and cover themselves with disastrous failure. It will be no use declaring, as has been done before, that every recurring crisis in the department is manufactured from without; that has never been, nor can be, and is not so now; the mischief has always been internal, as it is at the present moment.

It is quite impossible to discuss in a short article all the evils causing the present falling-off of candidates; but they are well known, and seem to be thoroughly appreciated in the schools; we can only mention the more prominent. First, the position of the medical officer to the rest of the army is most unsatisfactory, and to high-spirited, self-respecting men, intolerable. An attempt has been made, by some in high places, to inculcate in the army that, although

the medical officer is in it, he is not of it; an impossible and illogical position, the absurdity of which the humblest private can see through, when he knows that nothing can be done or is done in military duty without the intervention of the doctor. But such teaching has done infinite mischief in fostering class and caste exclusiveness, which comes out in the shameful blackballing of medical officers in certain military clubs, and their being often practically ostracised in garrison life. They therefore claim full equality of status with other officers, without which young medical men will not enter the army.

Then, the conditions of foreign service, especially in India, are exceedingly hard and destructive to health. The Medical Staff, especially the ill-paid juniors, consider themselves both literally and metaphorically "sweated" by the Indian Government; they experience all the disadvantages without enjoying any of the advantages which fall to their brethren of the Indian Medical Service.

Of course there are others, but these two are the chief causes, so far as we can judge, which are bringing the Army Medical Service into disrepute. We shall be curious to see how a reorganised War Office proposes to deal with them.

THE MALARIAL PARASITE.

DR. DANIELS, of British Guiana, whose interesting letter we publish to-day, is another of the rapidly-growing cloud of witnesses testifying to the truth and value of Laveran's discovery. Dr. Daniels is favourably known as a skilled pathologist; he has enjoyed exceptional opportunities for the study of malaria, and of these he has not failed to avail himself, as his contributions to the British Guiana Branch of the British Medical Association, published in the *Medical Annual* issued by that Branch, and elsewhere, amply testify. What he has to say on this and cognate subjects has, therefore, a distinct claim on our attention.

The tendency of his letter, we remark, is rather to depreciate than to uphold the finding or otherwise of the malaria parasite as a reliable and practical test of the presence or absence of malarial infection. It must be conceded at once that cases do occur in which the parasite is not to be found in the peripheral circulation at all times of a malarial fever cycle, and perhaps that in a very few instances it may not be present in the peripheral circulation at any time during the first twenty-four hours or so of a malarial attack; but, on the other hand, the weight of evidence tends to indicate that in all ordinary cases of ague, and of what used to be called malarial remittent, the parasite is to be found always or at some period or other of the fever cycle most readily in intermittents during or just before the rigor stage and during the rise of temperature, and in the case of remittents at the commencement of the exacerbations.

In the vast majority of instances the parasite, or its product (malaria melanin), can be seen in greater or less profusion throughout the fever, and until quinine has been taken, and at any time of the day or night. For the most part, to find the parasite or its product is simply a question of proper preparation, of perseverance, and familiarity with the appearances the animal assumes. As we mentioned some time ago, Thayer and Howatson state that, "excepting in two or three instances, where the patients entered the hospital during convalescence, the specific organism was

found in every case of malarial fever treated in the wards," and the number, 616, was no insignificant one. Other good authorities tell us that sometimes they fail to find the parasite, but they also say that such failure is a rare event and that the longer they work at the subject the fewer their failures become. This was Laveran's experience, and Manson speaks very much to the same effect. So that while admitting with Dr. Daniels that the distribution of the parasite in the circulation is not always and merely a mechanical affair, that the specific organism exhibits a marked predilection for certain organs, and that cases do occur in which it is not found in the peripheral circulation, such cases of complete absence from the general circulation are distinctly rare. Dr. Daniels's comparison with the *filaria* gives an exaggerated idea of the frequency of this occurrence; rather, we would say, the malaria parasite in finger blood is as valuable and reliable a test of malaria as the tubercle bacillus in the sputum is of phthisis.

It is well known that there are many fevers in warm climates which are not malarial and which do not fall into line with the recognised types. Perhaps many of the British Guiana fevers are of this nature. It would be interesting and useful to have from Dr. Daniels careful clinical records of those cases of fever in which he failed to find the malaria parasite, to see their temperature charts, to have a definite statement of the number and times of blood examinations in each, together with a statement as to the influence quinine had on the symptoms and progress of each case.

The malarial fevers met with in London are generally relapses and are seldom severe; in fact if left alone a large proportion of them recover spontaneously and without the use of quinine. The infection, in the first instance acquired in the tropics and usually attended with fever which was quickly got under by quinine, remains latent for a considerable number of weeks or even months. On the patient entering our cold and stormy climate some exposure or imprudence brings about a relapse. Accordingly we find that these relapses are much more frequently met with here during the winter or during bad weather. In such cases, Dr. Manson informs us, the malaria parasite—no matter the type of the fever, whether mild or more severe—can invariably be detected in the peripheral circulation.

All this shows—what we have so often insisted on—the necessity there is for the practical instruction in this important branch of medicine of medical men intending to practise abroad. Men require to be shown when and how to find the parasite, and they ought to have it demonstrated to them over and over again. If this could be done there would be less scepticism on the subject and a better appreciation of its practical value. Failure to find the plasmodium may depend in the case of the small unpigmented varieties on the minuteness of the object, on imperfect preparation of slides, and on wrong times being selected for examination; but, given properly prepared slides, one used to the work can find the parasite in practically every case of untreated malaria; the larger and pigmented forms are so definite, so clear that, we repeat, "a child could recognise them."

CITY OF DUBLIN HOSPITAL.—Dr. Henry Fitzgibbon has resigned his position as surgeon to the City of Dublin Hospital. The appointment of his successor will take place on November 5th.

At the annual meeting of the Royal College of Surgeons of Edinburgh on October 16th, Emeritus Professor John Struthers, M.D., LL.D., was elected President for the ensuing year.

A CLINICAL demonstration (drawings and patients) will be given by the Neurological Society of London at Mr. Hutchinson's Museum, 1, Park Crescent, Regent's Park, on Thursday, November 7th, at 8.30 P.M.

It is proposed to entertain Sir Thornley Stoker, President of the Royal College of Surgeons in Ireland at dinner on Saturday, November 2nd, on the occasion of his receiving the honour of knighthood.

FOLLOWING the example of abstaining medical practitioners in Britain and in America in the British and American Medical Temperance Associations, between twenty and thirty Continental physicians who are abstainers have recently founded a Continental Medical Temperance Association. Alienist physicians occupy a prominent place in this new undertaking, the first president of which is Dr. Smith, of Grossherz, Baden. On the continent of Europe, such a medical society, based on the abstinence of its members, is of considerably greater significance than the similar associations in the United States and England.

MRS. GLADSTONE, though much better than she was a few days ago, is still weak. Ever since a severe attack of influenza from which she suffered last year she has been troubled with a sequel of a debilitating nature, and she overtaxed her strength during the summer owing to her devotion to social duty and philanthropic work. Her recent illness was, we understand, due to an aggravation of certain infirmities of age, but from this she has now, we are happy to say, recovered. Although subject now and then to vertiginous attacks, her pulse is good and her general vitality for a woman of her age is wonderful. Her distinguished husband had a slight cold a week ago, but is now, we have the best authority for stating, wonderfully well.

THE ROYAL COLLEGE OF PHYSICIANS.

THE delivery of the Harveian Oration at the College on St. Luke's Day, October 18th, was attended by a large number of physicians and guests, among the latter being Sir J. Paget, Sir J. Lister, and the Hon. G. Denman. The chair was occupied by the President, Sir Russell Reynolds. The oration, by Dr. W. S. Church, is published in another column. At the conclusion of the address, the President awarded the Baly Medal to Dr. W. H. Gaskell, F.R.S., of Cambridge, in respect of the great advances in physiology to which his researches have contributed.

MEDICAL PRACTICE IN SOUTH AFRICA.

SOME time ago a statement was published in the press to the effect that there was a dearth of medical practitioners in South Africa, and Cape Town, Johannesburg, and Barberton were mentioned as places where this dearth was particularly felt. A correspondent who has practised for more than twenty years at the Cape thinks that this reckless statement, calculated to cause unnecessary anxiety to persons in this country who have friends and relatives in the places mentioned, and calculated also to raise false hopes in the minds of young medical men here, ought to be contradicted. Those who are regular readers of the *BRITISH MEDICAL JOURNAL* will be aware that so far from there being a dearth of medical men—at least in the more important towns—there is something very like a plethora. Thus our correspondent states that in Cape Town and the surrounding district, with about 95,000 inhabitants, there are over fifty medical practitioners; in Johannesburg, with a population of 70,000,

there are some 120 medical practitioners. Altogether, in South Africa, there are about 600, and the official *Colonial Medical and Pharmacy Register of the Cape of Good Hope*, a volume published with the sanction of the Cape Government, contains the names of all registered medical practitioners, and information also as to dentists, pharmacists, midwives, and nurses. The notion that a lady, or anybody else at the Cape who wants reliable treatment, must travel to Europe to obtain it is one of those pieces of perverse feminine exaggeration with which we are all familiar, and to which the majority of us pay very little heed.

GOOD SERVICE REWARDS.

THE recent sad mortality in the senior retired list of the Army Medical Service leaves vacant the appointment of one honorary physician and two honorary surgeons to the Queen. Likewise three good service pensions are vacant. Such a remarkable occurrence suggests once more the question often asked before: Why should all these honours and rewards go to the highest rank only? Are there none in the lower ranks worthy of such distinction? It is certain that only a mere fraction of those entering the service can ever reach the highest grade, and it may be open to question whether the ablest and most meritorious do. As matters stand, only the highest paid and pensioned officers get the good service pensions, and those who are lucky enough to reach the topmost rung of the ladder the honours. A surgeon-major, even if a very Syme or a Clark, could never wear the honorary sash; and it is equally certain he could never expect an extra sixpence of pension.

ST. WINEFRIDE'S WELL.

EVEN miraculous cures have their financial side nowadays, and there is a flavour of anachronism in the discussion at a *fin de siècle* district council meeting of the terms upon which St. Winefride's well, at Holywell, is to be let to the priest in charge of the Roman Catholic Mission. It seems that the enormous number of pilgrims attracted by the reputation of the shrine suggested to the district council the mundane consideration of raising the rent some 50 per cent., although it was urged with much show of reason that the town already benefited by the influx of visitors. Upon the question of granting a lease the secular tone became still more pronounced, but the proposition that "if a man improved his business and had his rent raised he should have some security for the future" failed to find adequate support, and it was decided to exact £150 per annum, without lease, in place of the £100 hitherto paid. So at least the *Manchester City News* says.

CANON BARNETT ON A USE OF CONVALESCENT HOSPITALS IN WINTER.

DURING last winter the workhouses, and in some cases the infirmaries, were crowded beyond what either health or decency permitted, and this is sure to occur again unless some plan can be devised to meet the need of increased accommodation. From the fertile brain of Canon Barnett comes to us a suggestion which seems to be pregnant with possibilities alike for the aged poor, the over-burdened rate-supported establishments, and certain charitable institutions. He suggests that the convalescent hospitals and homes (which, thanks to the philanthropy of the rich, exist in considerable numbers) should be utilised for the housing of some of the aged and respectable poor during the winter, the guardians paying for their support. By this plan hundreds of beds which now remain vacant and useless would be filled, and the old folk would probably enjoy the change to the seaside or into the country, and the pressure for accommodation, which is now as certain to come as November and December, would be relieved. Added to these advantages there would be the indirect gain that the

convalescent hospitals would be enabled to retain their staff throughout the year; one of the difficulties to which all these institutions are subject being the inability to keep their officers and servants during the slack season, and the constant changes of staff make the summer work specially trying. To carry through such a plan it would be imperative that only the respectable and amenable poor should be drafted to the convalescent homes, where to some extent discipline might be relaxed and individual eccentricities studied. This attempt at classification would render easier the task—which must always be a difficult one—of treating the casual poor with the amount of severity which would tend to deter them from too readily seeking the workhouse, combined with the justice which is the desert of every human being, however erring. From previous experience of the cumbersome machinery by which the Local Government Board maintains control over the Poor-law interests, we are doubtful whether such a plan as is here suggested could be carried out. If not it is but another argument to add to those we have many times adduced for the removal of all Poor-law matters from the immediate and detailed control of the Local Government Board, in order to place them under the care of a central metropolitan committee which would be small enough to be elastic, and large enough to command the respect and attention which the public are no longer able to accord to Boards of Guardians.

PURE BEER.

If adulteration of beer and other alcoholic beverages were practised to anything like the extent that is sometimes stated there would be great need for increased vigilance on the part of the public analyst. It is satisfactory, however, to know that whatever mischief may result from misuse of beer, there is little reason for believing that the presence of abnormal noxious ingredients is often, if at all, responsible for such results. An instructive article on this subject has recently been published in the *Standard*, which should altogether confute the sentimental assumption that beer at the present day is more deleterious than it was in the "good old days of home-brewed malt and hops." All known facts point in the opposite direction. The art of brewing is better understood and better carried out than it used to be, and although the use of sugar as a partial substitute for malt is permitted, the intoxicating effect of beer is just the same, whether the alcohol it contains has been derived entirely by fermentation of sugar produced from the starch of malt or in part from sugar added in the brewing. There is probably no article of consumption that is subject to more frequent systematic analytical examination than beer, but the number of instances in which adulteration is detected is comparatively very small, and then the main feature of the adulteration is dilution with water. In this respect there is indeed a vast improvement upon the practice that was not uncommon some fifty years ago of giving unnatural potency to beer by the use of *coccus indicus*, grains of paradise and coriander seeds, etc. The strict supervision of breweries by the Inland Revenue officers is a sufficient protection against such improper practices being carried on there and even in publichouses, the possibility of adulteration is but very limited.

HOSPITAL ACCOMMODATION IN LONDON.

Provision was made recently to the difficulty experienced in Marylebone in connection with the removal to hospital of infectious cases, owing to the large demands which are being now made upon the accommodation of the Metropolitan Asylums Board hospitals. Mr. Wynter Blyth has recommended the adoption of bacteriological examination as a means of limiting the number of cases of sore throat in which removal to hospital is recommended. With the co-operation of medical men in the district, Mr. Blyth proposes, "while the hospitals are

so full, to adopt the Bristol system, and get a bacteriological examination of cases returned as diphtheria; the examinations, it will be understood, are not for the purpose of disputing, revising, or correcting a medical man's certificate, but for the purpose of ascertaining whether the case may be treated at home successfully with fair safety, or whether it should go to hospital." If this plan is carried into execution, its practical working will be watched with interest. If the examinations are to cease, however, as soon as the pressure on the hospitals subsides, the trial of the new system will not, it may be anticipated, be a very extended one.

THE SICK POOR IN IRISH WORKHOUSES: BAILIEBOROUGH.

At the Bailieborough Union Infirmary our Commissioner was challenged by a pauper inmate in these terms: "Can you tell me why I am shut up in prison? I have served my Queen and country well, I have my discharge and pension, but my liberty is taken from me as if I were a felon; will you please tell me why it is?" The old soldier's tale was true; he had a few privileges in the way of tea and tobacco from the guardians, who take his pension, but he is never allowed to go from the precincts of the house, and he with the other inmates pass almost the whole of their life, waking and sleeping, in the bare and filthy wards, condemned by the medical officer as "quite unfit for their purpose; no alteration can make them suitable." As our Commissioner says, the infirm patients are worse fed, worse clothed, worse housed than criminals, and, like criminals, they are deprived of their liberty. Dirt, neglect, pauper nursing, insanitary conditions, these things we have found in many English houses, but the senseless rule of "no leave out" obtains only in the sister island. Bailieborough, except in the possession of a medical officer who has the knowledge and the courage to denounce abuses (notably pauper nurses, who levy blackmail), appears to be without a single redeeming feature. Perhaps the blackest spot in its management is the treatment of the idiots and feeble-minded, who are shut by twos into unwarmed cells, lighted by a narrow slit. They have no employment, no care but that of pauper inmates, no place for exercise but a stone-paved yard; they are far worse off than the pigs on any decent farm. How long shall these things be?

LEPROSY AND ITS ALLEGED CURE.

WITHIN the last few days paragraphs have been appearing in the newspapers under such headings as "The Cure of Leprosy," "The Treatment of Leprosy; Important Discovery," and the like, based upon an "interview" with Dr. Impey, who has recently arrived from the Cape of Good Hope. The public memory is a short one, and no doubt little is now remembered of the great results which were promised from the exploits of certain ladies who were duly "boomed" by sensational pressmen when the subject of leprosy was before the public. Dr. Impey, if he has made any observations of value in connection with the treatment of leprosy, will find no difficulty in making them known to those who have the care of leprosy patients, nor in setting them in the usual manner before the medical profession at large. As far as we can gather from the remarks which purport to have been taken down by the reporter, the "important discovery" and "the cure of leprosy" seem to consist in the inoculation of lepers with the virus of erysipelas. This is by no means the first time that a treatment of the kind has been proposed; everybody knows that such an inoculation has been practised with a certain advantage in cases of cancerous disease, and that this is only one of the numerous developments of the new therapeutics which we largely owe to the initiation of Pasteur's work; but it appears not to be so generally known that the inoculation of erysipelas in leprosy subjects has been already practised, and some of the results published. Indeed, experiments in the direction of the

sero-therapeutics of leprosy are probably now in progress in many parts of the world, and it is to be hoped that it is the reporter's mistake that makes Dr. Impey pose as the "discoverer" of any such methods for the cure of leprosy. It is, moreover, by no means desirable that theories and observations not yet fully worked out should be published in the general press. The hopes of sufferers may thereby be cruelly raised, and the only result, as we have said, may be the temporary notoriety of the "discoverer."

LUNATICS AT LARGE.

WE commented recently upon a series of murderous assaults done by lunatics, most of whom had been discharged from asylums. Several persons lost their lives through these assaults, and several others were very severely and dangerously injured. Much questioning has arisen in consequence concerning the working of those provisions of the Lunacy Act which deal with the subject of the continuation or non-continuation of "reception orders" by medical officers of asylums in the cases of those insane persons who, although better, are still in a condition in which, under slightly disturbing influences, or without any such, they may easily be brought, on relapse, into a state of homicidal or otherwise dangerous insanity. Our remarks in the commentary above cited are accentuated by the report of an occurrence similar to those already referred to. A man who had just been released from a lunatic asylum, whilst walking in Glasgow Green, happened to see a woman lying asleep on the grass, a woman a stranger to him, one who had never done him any harm or given him any provocation. But here was an inviting opportunity for the freed lunatic with homicidal tendencies; the favourable conditions probably suggested the homicidal idea, which, rising promptly into an impulsive force, issued in the impulsive and fatal act; for the lunatic forthwith smashed in the skull of the sleeping woman with a hammer. Perhaps the public will some day become tired of this sort of proceeding, and will insist upon power being given to asylum authorities to detain those who have been lunatic, and although improved, are really lunatic or excessively unstable still, and who, if set free, are sources of danger and perhaps of loss of life to their fellow-subjects.

THE HYPNOTISM OF "TRILBY."

THE pivot on which Mr. Du Maurier's extremely able and popular book depends is a hypnotic phenomenon of which the publicity is adversely criticised in many well-informed quarters. Mr. Ernest Hart, however, the author of *Hypnotism, Mesmerism, and the New Witchcraft*, of which no small part is devoted to exposing many of the shams and impostures exhibited and described under that title, is of opinion that while Mr. Du Maurier has with dramatic and artistic instincts somewhat stretched the working probabilities of hypnotic condition beyond the ordinary limits, and has artistically concealed the difficulties and mechanism by which his striking effects are produced, he has, nevertheless, not outstepped the bounds of possibility. Of course, to the uninformed critic and observer the mere fact of the apparent endowment of Trilby under the influence of suggestion with powers and capacities which she does not possess otherwise or at other times than when placed under this influence appears either miraculous or false, or suggestive of some new force, some transference of nerve power or some so-called magnetic influence, to use the ordinary jargon. Those who have followed Charcot, or who agree with Mr. Hart in his analysis of the phenomena known as suggestion or hypnotism, hold that no such agencies exist, and the phenomena such as those which the hypnotic state presents are due to the transformation effected in a perfectly natural and physiological manner in the subject under the influence of external or automenal suggestion. It is by no

means uncommon—and of this many instances have been widely observed, and are recorded in Mr. Hart's book—to find persons who, under the influence of suggestion, and when in the deep hypnotic state, are capable of fits of strength and of agility, of intense dramatic expression and matchless emotional effects, as may be seen in the photographs which have appeared in our columns when these articles were running through them, or in their collected form in the book itself. Superficially and at first it might appear that some new quality has been added, and some mental endowment as it were freshly injected into the subject: on more careful study, this is found not to be so. The ordinary individual is impeded in such dangerous efforts as leaping on narrow ledges, climbing the walls of a room, or in adopting the rapidly changing and intensely emotional attitudes and expressions by the inhibitory influence of fear or shyness and interfering mental emotion, and of other jarring and inhibitory influences. In the hypnotic state and under the influence of suggestion inhibition ceases, the individual is unconscious of danger, and *pro tanto* insusceptible of fear. The shyness, the awkwardness, the want of muscular exactness and intensity of effort produced by these interfering agencies are removed, and the subject becomes a machine wholly subject to the expressed will from without with which there is nothing to interfere. The elaborate lessons of Svengali in vocalisation and dramatic passion might quite conceivably transform Trilby, who possesses a magnificent vocal organ, into a dramatic singer of the highest order. Under the conditions which Mr. Du Maurier carefully and accurately indicates of perfect hypnotic subjection, of complete abstraction from interfering external or internal influences, Trilby, when she sings, is in a perfect hypnotic sleep; she is unconscious of her audience and unaware of her surroundings. She is, like all thorough hypnotics, reduced to the state of a marvellous machine, capable of receiving the most perfect training and in complete subjection to the will and the suggestion of the operator. The state is one of exaltation of certain muscular and mental functions, due to the removal of all inhibitory influences. It is quite characteristic that while in this condition she performs the marvellous feat ascribed to her in the book but she has no recollection of anything she has done while in this condition. When, however, the presence and the suggestive influence of her teacher are removed she relapses into complete and bewildered incompetency, for no new faculty has been added, no new mental power has been given; the influence is only that of training in the hypnotic state and under the suggestion, and when these motor conditions are removed she is no better, but rather worse, in her last state than in her first. Mr. Du Maurier may be congratulated on having produced for the first time a literary masterpiece in which the conditions of hypnotism are used with the power of genius, and in which their limitations and nature are correctly indicated if not fully analysed or described.

A DANGEROUS VOYAGE.

SOMETHING like a panic has, it is said, arisen on the Liverpool Exchange, owing to the death of one well-known merchant and the serious illness of several others. All were members of a party who accepted an invitation of the Manchester Cotton Brokers' Association to travel from Liverpool to Manchester by the Ship Canal on September 21st. During the journey complaints were made as to the foul smell arising from the canal when its waters were stirred up by the steamboat. So distasteful was this to some members of the party that they left the boat at the first stopping place, and returned to Manchester. It is confidently asserted that the illness of several members of the party and the death of one are to be attributed to infection contracted from the waters of the canal during the picnic. This theory appears hardly to have been proved, but it is not disputed that a considerable quantity of sewage finds its way into the canal, so that it is

not impossible, though, so far as we have been able to learn, all the cases of illness have occurred among the Liverpool guests, and none among the Manchester hosts. Whatever the condition of the Ship Canal, it cannot be denied that the Irwell, up which the Liverpool party subsequently travelled in a steam launch, is a pestilential stream and a disgrace to a great and enlightened city such as Manchester.

FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION OF PORTSMOUTH.

PROFESSIONAL union and medical defence have been largely discussed in the provincial centres of the British Medical Association during the last few months, and the outcome, we hope, will be the development of a higher standard of professional ethics and intercourse. The Council of the Association have given their unanimous support to the united action of the general practitioners in the South of Ireland during the long and hard battle which has been fought there against the unfair action of the local benefit clubs by the admission of well-to-do persons who have no right to their help. We shall be glad to hear that the united and honourable conduct of our brethren in Cork has been crowned with success. In the south of England too another battle of the clubs is now raging, and the contest is between the medical profession of Portsmouth and the local friendly societies. One large and influential club in that neighbourhood has called upon its medical officers to accept the splendid remuneration of 2s. 6d. per annum for day and night attendance on infants from 3 months to 3 years of age, and 2s. per annum for attendance upon the other juveniles from 3 to 15 years of age. It is a matter of congratulation, under these circumstances, that a Portsmouth medical union has been inaugurated, and that its members have unanimously refused these terms and have resolved to accept nothing less than 4s. per annum per member for all ages. We sincerely hope that firm and wise union will prevail in this new centre of medical defence, and that the contest will be carried to a successful termination. The medical men of Portsmouth are to be congratulated on their unanimity, and we trust that no outside doctors will be induced to accept the sweating system which these societies are endeavouring to establish. Our Portsmouth brethren will receive the hearty support of all the members of the British Medical Association, for in this high and honourable action they are fighting a battle not only for themselves but also for the general practitioners of the country.

THE MEDICAL ENTRIES IN THE PROVINCES.

By the courtesy of the officers of the several institutions, we are now enabled to complete the returns of the number of new medical students. The tutors of colleges and other officers of Cambridge University have kindly furnished returns, from which it appears that the entry of medical students there is larger than in any previous year. Up to the time of writing 151 of the 808 freshmen just matriculated have indicated their intention of studying for the degrees of M.B. and B.C. Nearly 200 students are dissecting. At the University of Durham College of Medicine, Newcastle-on-Tyne, 24 new students have entered this session for the full curriculum, and 37 have joined for special classes. At Owens College, Manchester, 68 students have entered for the full curriculum, 60 for special classes, 62 for the preliminary scientific course, and there are 13 dental students. At University College, Liverpool, there are 37 new students entered for the full curriculum, 23 have joined special classes, 28 the classes in preliminary scientific subjects, and there are 11 dental students. At the Oxford University it does not appear to be possible to ascertain how many freshmen intend to study medicine. Excluding Oxford, then, it would appear that 396 new students have begun the study of medicine this session in the provinces as compared with 581 in London. The figures indicate a

remarkable growth in the provincial schools, though the large share which Cambridge has in raising the total diminishes to that extent the apparent loss of the London schools. The majority, probably the very large majority, of Cambridge men, after spending three years there, come to London to take the practical clinical classes in medicine, surgery, and midwifery at one or other of the London hospitals. There are many advantages attending this procedure, and it is not likely to become less popular, but it should not be forgotten that Cambridge's gain is not all London's loss. [We are asked to state that the number of students entered for the Preliminary Scientific Course at the Yorkshire College, Leeds, is 19, and not 17 as stated previously.]

INCREASE OF DIPHTHERIA IN LONDON.

DURING the past few weeks the mortality from diphtheria in London has shown a tendency to increase, and last week it was higher than in any week since the end of 1893. The deaths referred to this disease in the metropolis, which had been 44 and 56 in the two preceding weeks, further rose to 76 during the week ending Saturday last, October 19th. This number is nearly double the average for the corresponding week of the ten preceding years 1885-94. The mortality was practically confined to children, 51 of the 76 deaths recorded last week being of children under 5 years of age, and 24 of young persons aged between 5 and 20 years, nearly all of whom were under 10 years of age. Only one of the 76 deaths was a person aged upwards of 20 years. After distributing the fatal cases that occurred in the Metropolitan Asylums Hospitals and other institutions to the sanitary areas in which the patients had previously resided, it appears that 6 cases belonged to Kensington, 6 to Camberwell, 5 to Marylebone, 5 to St. Pancras, 5 to Mile End Old Town, 5 to Greenwich, 4 to Fulham, 4 to Shoreditch, and 4 to Battersea sanitary areas. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last was 667, and 115 new cases were admitted during the week.

AUSTRIAN OLD-AGE HOMES.

THE reports of our Special Commissioner have shown, in the most indisputable and striking manner, that the treatment of the sick and aged in our workhouses needs amendment. When we find ourselves nationally at fault, it cannot but be useful and instructive to see what other nations do under the similar circumstances in which we have failed. Miss Edith Sellers's article on "Old-Age Homes in Austria," published in a recent number of the *Nineteenth Century*, should therefore be read with interest at the moment that we find our workhouse system needs in some respects reform. All persons, it seems, who have a right of settlement in Vienna—that is, about 38 per cent. of the inhabitants—may on or after their sixtieth birthday claim either a pension, or admission to an old-age home, always providing they cannot support themselves, and have no relations legally bound to support them. There is room for about 4,000 persons in these institutions, but as the demand for admission is four times greater than the accommodation the Poor-law authorities exercise a discretionary power, and give the preference to persons of good character. The homes are all large, with fine gardens attached; the inmates may retain their special little belongings, and they wear their own clothes. Men and women sleep in separate dormitories, but married couples and members of a family can be together as much as they wish during the day. Each person is given 28 kreutzers (about 8d.) a day for food, and large restaurants are kept by the authorities, at which meals are taken at separate tables, and selected from a varied, but extremely low-priced, menu. Before any of the dishes are served the director of the home and the doctor must certify that their ingredients are excellent, and that they are well cooked. Invalids and the feeble-minded

have rations. Those who are willing and able can earn small wages at carpentering, tailoring, shoemaking, etc. Each room has a *Stubvater* or *Stubmutter* whose duty it is to keep the place orderly and to look after the feeble. For this service a payment of 6 kreutzers a day is made. In the rooms set apart for invalids the "house fathers" and "house mothers" are replaced by nurses. Once a month in each house the officials, the clergyman, the doctors, and a representative of the Poor-law Department sit in conference, and the inmates are invited to appear before them and make known their wishes and grievances. The result of thus treating worn-out old working people as human creatures, with the likes and dislikes, the small interests, and the self-respect of ordinary folk is, as Miss Sellers says, that "it would be difficult to find a more contented set of old people." Certain improvements are suggested, such as the separation of the incurably ill from the others in a house of their own; and the dormitories are said to be too large. The cost of these free and happy homes for the aged poor compares favourably with our workhouses. In Vienna the cost per head is about 11d. a day; in London workhouses it reaches an average of 1s 4½d. In England we have tried barracks and the regimental system in treating the young and the old of the pauper class, and they have signally failed. It is time we tried now a more human system, not so destructive of the varying influences and interests of family life.

MEDICAL ADVERTISING.

In another column we print a letter from "Anglo-Celt" in which are expressed some sentiments which no doubt are more or less present to the minds of many struggling practitioners. Why should not the medical man take certain opportunities of advertising his name and calling? The clergy advertise their sermons, lawyers make orations in public, and so on. Let us consider for a moment what it is that a physician would advertise. He would advertise not goods which can be tested by appropriate means; not sermons, in which case the public, which goes to hear, is the best and final judge of that which it needs; nor again speeches which are to be estimated there and then by their success in convincing a judge or bamboozling a jury; but certain personal qualities of learning and character which cannot be estimated at the moment, which indeed at the moment may seem disproportionately simple and unpretending, and in any case are beyond the scope of even intelligent criticism, except in a very general sense. In a race of advertisers, and of advertisers whose wares cannot be directly appraised, it is easy to see who will win, and that this will be the man of the loudest voice and the fewest scruples. Again it is to be remembered that the business of a physician is carried on in secret; in such a calling it is not only necessary to lead the public to trust in our reticence and unselfishness; but, within our own ranks, to make habitual a sense of loyalty and consideration for our professional brethren, under circumstances of great temptation, when a stab in the dark can be given with deadly effect and never found out. These are not virtues which will flourish under that discipline which consists in the gospel of "the devil take the hindmost." At the same time, we think some of our correspondents may regard public lectures and the like by medical men in too censorious a light. Much depends upon the good taste and propriety shown on the particular occasion.

MEDICAL AID FREE! WITH A POUND OF TEA!

In the *BRITISH MEDICAL JOURNAL* of September 14th, p. 673, attention was called to a medical aid scheme carried on by Bryan Brothers, grocers, Dale Street, Liverpool. Customers who took "one-quarter pound of our famous tea every week" were to be provided by the firm with medical attendance free of charge. The customer received a card headed "Bryan Bros. Free Medical Aid Scheme," and containing a "List of Medical Officers for this District." A letter from

one of the three medical practitioners whose names were printed on the card was published in the *JOURNAL* of September 21st, p. 748. This letter stated that our correspondent had realised "the very great mistake" he had made in permitting himself to be associated with such a scheme, and that he had ceased to be in any way connected with it. We have not, however, received any communication from the other two medical men whose names appeared on the card. Are we to assume that they retain their connection with this new development of a pernicious system? To this question the profession is entitled to receive a categorical reply. The names on the card were; "J. B. Forster, Esq., L.R.C.S.I., 27, Breckfield Road North, Liverpool," and "W. M. Pries, Esq., M.R.C.S.Eng., etc., 131, Queen's Road, Liverpool."

THE LATE DR. ROBERT BROWN.

A PORTRAIT bust of Dr. Robert Brown, the distinguished botanist, was recently unveiled in his native town, Montrose, Forfarshire. Beneath the bust is a tablet with the following inscription: "Robert Brown, D.C.I. Oxon., LL.D. Edin., F.R.S. Lond., President of the Linnean Society, Member of the Institute of France. Born in this house 21st December, 1773; died in London 10th June, 1880. 'Botanicum facile princeps.' Alex. von Humboldt." The bust is in bronze, by Mr. D. W. Stevenson, R.S.A., and was unveiled by Miss Paton, Linkhouse, Montrose, a relative of Dr. Brown's. At a reception held by the Provost, magistrates, and town council of Montrose, a large number of distinguished botanists from all parts of the kingdom were present, and among the speakers were Mr. Carruthers, ex-president of the Linnean Society, and formerly Curator of the Botanical Department of the British Museum; Mr. George B. Murray, Curator of the Botanical Department of the British Museum; Professor Balfour, of Edinburgh; Professor Bower, of Glasgow; Professor Traill, of Aberdeen; and Professor Geddes, of Edinburgh.

NURSING IN IRISH WORKHOUSES.

THERE is a perfect storm of indignation in Ireland over the effort to improve the nursing in the workhouses. The reason is that in a large number of them the nurses are nuns, and that any doubt as to the efficiency of these ladies as nurses is regarded as something of an insult. That was, perhaps, to be expected, and we sympathise with the Local Government Board in the difficulty with which they are confronted. For ourselves, we know that these ladies have done estimable services in many of the workhouses, and we should be very sorry if their good influence and their devotion to well-doing were lost to the poor inmates. But we must point out that they are not trained in nursing. We observe that ill-informed persons say that some lady has been seven or more years in the workhouse, and she must therefore be a trained nurse. Of course that is absurd. A lady might be fifty years in a hospital and still be an untrained nurse; just as a man may attend lectures and hospitals and be quite ignorant of even elementary facts. There is no training in workhouses, and the sooner that this is recognised the better. The Dublin Roman Catholic hospitals have now lay nurses, and this is a sufficient answer to those who refuse to have any improvement made in the workhouses. If the guardians everywhere, including Dublin, would only look at the whole question of workhouse hospital management with a little calmness, and with less belief in their own perfection, much might be done for the sick pauper. We are sure that this will come. The guardians are rather unaccustomed to intrusion upon their easy-going system, and they resent any disturbance. But they must bow to the force of facts.

SUCCESSFUL VACCINATION.—Dr. J. Lockhart Livingston, Public Vaccinator of the Hursley Union, near Winchester, has been awarded, for the second time, the Government grant for successful vaccination.

REPORTS ON THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

V.—BAILIEBOROUGH UNION, CO. CAVAN.

THIS house is situated in a remote country district on the outskirts of a town of the same name. It is a medium-sized house, and was more than half empty when we visited it. Dr. Ryan, the medical officer, to whose house we drove, readily accompanied us to the workhouse, and under his escort we found our way into

THE FEVER HOSPITAL,

which stands to the left of the body of the house and between it and the infirmary, making with a low building opposite a square enclosure, the body of the house and the infirmary forming the other sides. There is accommodation in this block for twenty-eight patients, but on this day it was empty. The wards are on the first floor, the ground floor being occupied by two large flagged rooms not in use at present, though we thought that one might be advantageously turned into a laundry for this block. The rooms above are two long wards for male and female cases respectively, the nurses' rooms being between, and a slice taken off one ward forms the hospital kitchen. The bed spaces on each side are platforms raised about 6 inches, leaving a sunk path down the middle; this construction represents a period in social history when straw ticks placed on the ground were the beds of the inmates, a custom which still prevails in the dormitories for the able-bodied in the majority of the workhouses. The wards were empty of all furniture but a few wire-mattress beds on trial and the barrow bed and ticks. The walls are rough surface whitewashed, and from their appearance we should say that they offered every facility for the lodgment and subsequent dissemination of germs; no care bestowed on their cleansing could ever make them antiseptic; the roof is pitched, the rafters being exposed. The little kitchen looked thoroughly businesslike, having a modern range, one of the best that we have yet seen in our rambles.

There is a permanent nurse in charge of this block, experienced but not trained, and she is assisted by her daughter, also untrained, who at this time was taking holiday duty for the nurse in the infirmary.

THE INFIRMARY,

in style like that of all the other houses, has 32 beds on two floors, 7 beds in each of the two lower wards, and 8 in each ward above, the lying-in ward containing 2. We saw patients in all these wards. The structure is quite unsuited for hospital purposes, the roof bare and open to the slates in the top wards, and the rafters unceiled in the ground floor rooms, the walls rough, having some remains of whitewash on the surface, small ill-fitting windows on one side, and air openings in the opposite wall, dirty floors, dirty beds crowded together, a few tumble-down chairs, an arm missing from one, a leg unsteady on another, the inevitable backless bench, old rusty grates, mugs of milk standing by the beds, a hunk of dry bread, sometimes on the floor, sometimes in a dirty handkerchief, made a picture of neglect—or shall we say of ignorance?—that was sad to see. The whole conditions are insanitary: the straw ticks and pillows resting against the wall, making a grimey mark or, as we heard, sometimes collecting blue mould; the continuous rail supporting the bed head enclosing a space between the wall and the uprights, the thorough cleansing of which is a task beyond the intelligence of the average pauper nurse (we saw the cakes of ancient dirt and dust under the beds); the absence of any closets or water supply inside the infirmary, necessitating the use of buckets or pails by day and night, the imperfect ventilation, these conditions fully bear out the statement of the medical

officer in his report: "The infirmary is quite unfit for its purpose; no alteration will make it suitable." Lodges, floors, benches, walls, patients, all stood in need of a thorough cleansing. As we only saw the one basin and towel in each ward for the patients, we were not surprised that they looked in want of a good wash. As we entered the male ward

AN OLD MAN,

hearing a strange voice, stood up, and saluting in military fashion said, "Can you tell me why I am shut up in prison? I have served my Queen and country well, I have my discharge and pension, but my liberty is taken from me as though I were a felon. Will you please tell me why it is?" The doctor, in explanation, told us that the man is a pensioner, but being friendless and old he has no other refuge than the house; that he pays his pension to the guardians, and he has a few indulgences—extra tobacco, tea, etc.—but since by the general orders he cannot go beyond the small yard attached to the infirmary, he is, in fact, that which he states himself to be—a prisoner. And this is the condition of all the aged, infirm, and sick, who are forced by stress of circumstances into the workhouse; they are worse fed, clothed, and housed, than criminals. We denounce the whole system as inhuman and barbarous, unworthy of a civilized country, and we will not cease to clamour for justice for the poor voiceless paupers and the old soldier seated on his hard wooden bench grieving over his wrongs.

THE OTHER PATIENTS,

many of whom were in bed, included some serious cases—an abdominal tumour, a man suffering from spinal injury, another with bronchitis, a case of hip-joint disease, anaemia, hemiplegia, and various forms of idiocy. There are no day-rooms, and, to quote again from the medical report, "the wards are too small, and the cubic space insufficient, for the number of patients who have to eat, sit, and sleep in the same apartment." The nurse (at this time absent on her holiday) is untrained; her assistants are the pauper inmates, one to each ward, and there is no night nurse. We are glad to read in the report from which we have quoted that the doctor protests against the pauper assistants, "who levy blackmail on the patients." The blackmailing of the helpless by the pauper placed in authority is known to every Poor law official, but as it is one of those abuses of which ignorance is commonly professed, we hail the fearless courage which notes the custom in a report which is published in the general press.

THE LYING-IN WARD

was occupied by a woman with her sickly child, placed here apart because its fretting disturbed the older patients. We judged from appearances that the case was marasmus; the little thing was much wasted, it was in a wooden cradle filled with straw; mother, infant, ward, all dirty, a mug of milk standing on a bench, and a piece of bread on the floor, were not suggestive of scientific feeding. *Apocryphal* of milk, we may mention here that it is served out once a day, and stands uncovered in the wards for the use of the sick. The circumstances surrounding this infant were not conducive to recovery. The confinements average ten in the year.

THE EPILEPTICS AND IDIOTS

are placed in the cells, which form the blocks at each end of the infirmary. These cells differ in no respect from those used for prisoners, except that they are unlocked during the day; a square flagged cell, whitewashed walls, slit in the wall for air, light and ventilation; a heavy door with ponderous bolt, crib beds filled with straw for the "dirty cases," and barrow beds for the less helpless, two patients in each cell, no means of warming these cells in the winter, but the borrowed heat from the fire in the corridor. We asked ourselves whether a trick of time had carried us back to the eighteenth century. The pathetic look of the hapless creatures, as they stared at us out of the cribs, haunted us for a long time; the darkness, the confinement, the want of employment, the stone yard for exercise, all seemed cunningly contrived to send them out of their minds. The attendants are pauper inmates, and this department is locked at 7 P.M. Here, again, we found the pails and buckets in the cells; one most offensive case gave quite sufficient proof that this class did not receive skilled nursing. We found

Paupers and their feeding troughs

THE AGED AND INFIRM

in their usual locality in the wings of the body of the house. We hesitate to repeat the same tale of dreary wards, dark and ill-lighted, destitute of comfort, noting the same listless group of aged inmates, the same want of cleanliness or of means for personal washing, lest our readers should think that we are filling up blanks from our imagination; but in this case we must even put in the shadows in darker colours, for it is hard to picture a more comfortless place than these wards for the old people. They are approached through day-rooms having mud floors, a long table at one end and a bench being all the furniture in these rooms. The whole ward was dirty, and smelt so, and the patients showed in their persons negligence and untidiness, but who could blame them when they had one basin and a towel to go round, no bath or lavatory, or decently clean clothing? There are 15 beds in these dormitories.

THE ONLY BATH

we saw was one in the male probationary ward; this answers to the tramps' wards in England, but from its appearance and odour we should say that it was put to other purposes to that for which it was intended. In all sanitary apparatus this workhouse is quite behind the times; pails and buckets are used all over the place, and outside there are privies which being at some little distance would not be available for the aged or infirm in bad weather. The privies are in a highly insanitary condition; no water is laid on inside the infirmary or the house. The water supply is taken from the lake; there is also a well in the precincts; the drinking water is drawn from the well. The drainage is into the lake and also into cesspools.

THE NURSERY

occupies a portion of the low building facing the fever hospital. It is a very dark stone-paved room, lit by small windows; it was more like a shed than a room, having rough stone walls, roof open to the rafters and slates, and a rusty grate. We saw about eight infants with their mothers; there was no evidence of nursing or supervision, and the condition of the infants appeared in no respect better than that of the children in the wayside cabin. To say that they were dirty and neglected is to use a mild term; a few wooden cribs filled with straw, infants in them; slatternly untidy mothers, with babies in their arms; some half-rinsed cloths on a string. At the other end of the room the beds used by the mothers at night. Needless to say, nothing to amuse the children. No bath or sanitary arrangement for this department, so that it is no wonder that neither infants nor nursery looked as though they were washed. We turned into

THE DINING HALL.

As the dinners were being served a few old men came in at one door, a few old women and children at another; they stood around the feeding troughs out of which they took the food, presumably porridge. Our illustration shows the feeding troughs, but in this case the inmates were standing to take their meal. No grace was said, no officer appeared to be present; it was like the feeding of animals, and not of human beings. The kitchen at the end of the hall was indescribably filthy; refuse, dirty straw, and cats were in the corners, the table was black with grease and dirt, the few utensils lying about were in the same condition; the walls and pitched roof black with grime and smoke, and the presiding genius of the kitchen, a male pauper, was in harmony with his surround-

ings. The laundry opposite was in the same condition—a broken sloppy floor, tubs of dirty water, a copper of which the brickwork was breaking down, no mangle or wringer; we could hardly believe that it would be possible to do any work in such a place.

RECOMMENDATIONS.

It is difficult to make any suggestion. Our readers will agree with the medical officer that the "infirmary is quite unfit for its purpose;" hence to suggest alterations of structure which will involve expenditure is only recommending a course that would be wasteful of the ratepayers' money. It seems to us that the best plan would be to make use of the fever hospital temporarily as an infirmary, making such improvements in the way of water supply and closets as would make it serviceable, and that a temporary building be erected for the infectious cases. With regard to the management, very much might be done to improve the cleanliness both of structure and inmates by efficient, energetic officers, who should be determined to do their duty in the face of almost superhuman difficulties. It would be possible if a larger staff were employed, both in the infirmary and the body of the house. The lunatics' condition requires the attention of the central authority, but until other and more humane arrangements are made for them there is nothing to prevent the guardians doing away with the cells and appointing paid attendants to take care of them. In the name of humanity we trust that the matter will have their immediate attention.

THE IRISH WORKHOUSE INQUIRY OF THE "BRITISH MEDICAL JOURNAL."

We are glad to see that the Irish papers continue to draw attention to our reports on the Irish workhouse infirmaries, and the *Irish News* says: "The conductors of the *BRITISH MEDICAL JOURNAL* are doing real service in the interest of the Irish poor who from want or sickness have to seek the shelter of the workhouse or infirmary. The *Journal* has gone to the expense of appointing a Special Commission to report on the administration of these institutions in Ireland. The Commission has only been a short time at work, but already it has made known the result of its investigations in several unions. The instalment relating to the Cooleshill Workhouse is certainly interesting reading. There is no suggestion that this workhouse is any better or worse than others of its class throughout the country; but the squalor and miserable surroundings of the inmates, both healthy and invalid, as pictured in the report, is, to say the least, no credit to the efficacy or humanity of our present Poor-law system. It has been the custom of the members of the Commission to give the guardians the benefit of the experience acquired in the course of their inspection by way of suggesting improvements, and it is, perhaps, the strongest commentary on the Cooleshill Workhouse building that they found it so unsuitable in every way that they hesitated to make any recommendation."

THE COVENTRY BOARD AND THE NIGHT NURSE.

We imagine that it is not often that a paragraph of the *BRITISH MEDICAL JOURNAL* finds itself doing duty as a handbill to summon an indignation meeting to protest against the action of a public body; such has been the use made of the note we made on the action of the Coventry Board of Guardians in refusing to appoint a night nurse for the infirmary. We are gratified to know that we have been of considerable use in aiding the people who have championed the cause of the paupers in the workhouse to carry their point. At the last weekly meeting of the Board it was proposed, seconded, and carried that a "certified night nurse be appointed for the infirmary."

NURSING AT THE BIRKENHEAD WORKHOUSE.

The Committee selected to inquire into the report made by Dr. Stansfield, the medical officer, respecting the alleged insufficiency and inefficiency of the nursing staff has met and heard both the doctor and the nurses. From the evidence it appeared that there were 200 patients and 5 nurses. Under these circumstances we are not surprised to read of any number of irregularities and mistakes on the part of a nursing staff that is set to do such an impossible task as to nurse 40 patients as the share of each nurse. The Committee regret the publicity that Dr. Stansfield has given to these complaints against the nursing staff, and, whilst admitting the truth of his statements in the main, remark that the reforms at which he aimed might have been easily obtained by quieter methods. Our experience is, on the contrary, that it is only by giving continued publicity to the medical officers' reports that the reforms at which they aim are accomplished.

THE DRUG TRADE IN THE UNITED STATES.—According to the *Pharmaceutical Era*, there are 36,352 retail drug stores in the United States, the ratio of population to each being 1,199, taking the figures of the 1890 census as a basis. It is estimated that in all probability there are 50,000 registered pharmacists, assistants, etc., employed in these stores. It is also estimated that there are in the United States over 2,000 establishments, with a capital of more than £20,000,000 engaged in the manufacture of drugs and chemicals.

WATER FILTERS.

We published on September 21st last an abstract of the tables in the report recently issued by the Prussian Army Medical Department, regarding the trials of water filters which have been conducted for them during the last three or four years. Those relating to the Berkefeld filter, a candle filter made in the Pasteur form, but of infusorial earth, were given in this report in the fullest detail. Briefly summarized, they showed that in a three years' continuous trial 37 specimens of this filter were set to work. As we stated in our abstract, "the output was in almost all cases found not only to be initially very high, but also, with periodical cleaning at short intervals, to remain so for long periods." In regard to their sterilising capacity, it was shown that 5 out of 37 remained unbroken and capable of preventing the passage of microbes at the end of their respective trials, varying from twelve days to three months. Four of the remaining 31 permitted the direct passage of microbes from the outset; 5 did so before the end of their respective trials, varying from five days up to three or four months; 1 passed microbes during its trial within eight to ten hours of sterilisation; 3 did so from the outset within twenty-four hours of sterilisation at some time previous to the termination of the trials, varying from five days to seven or eight months. The author accordingly states that it is necessary for these filters to be sterilised by boiling at least once a day; and he recommends for cases where they may be working during the night as well as the day that they should be sterilised twice every day. The process of sterilising is stated to take from an hour and a-half to two hours, it being risky to put the tube into water which is already boiling, or to use it after sterilisation before it has sufficiently cooled, owing to its liability to develop minute flaws. In regard to the mechanical strength of the filter tubes, 27 out of the 37 were broken during their respective trials, varying from nine days to seven or eight months.

We have received from the Berkefeld Filter Company, Limited, of London, a letter dated October 16th, in which they characterise our summary as inaccurate and injurious to their business interests. The letter does not give a single particular in which it is alleged that the results these tables of trials of the Berkefeld filter in actual use have been incompletely or unfairly stated. On the other hand, it attributes to the author of the report a statement that one of their patterns is "a model filter," when the statement in the original is that the filter in question is, in contradistinction to other types of the Berkefeld filter, "the normal model," and is so described in the subheading of the paragraph. It quotes a statement in the report that the processes of cleaning and sterilising used in the trials tried the filter severely, and that the maker described them as "killing" the tubes; but it omits the author's statement that these processes were necessary, and that the maker's comment was made in jest. It states that 48 tubes were successfully subjected to "a severe test," but it omits to explain that this test consisted in passing muddy water through them for an unstated time, and finding that after the indefinite number of seconds or minutes occupied in the process the filtrate was sterile—a test which Dr. Sims Woodhead and Dr. Wood have shown to be endurable by filters incapable of preventing even the direct passage of microbes. The Company quote further the opinion of Dr. Plagge that the results of the tables as summarised in our abstract—the fairness and accuracy of which are not disputed—are such as to "justify confidence and speak decidedly in favour of the Berkefeld filter." That is, as Dr. Plagge points out, a matter for the decision of the reader.

We take this occasion to repeat to makers of filters the warning which we have previously expressed that the time during which the sale of inadequate filters or of filters offered under unfounded claims will be permitted is, in our opinion, rapidly drawing to an end. The interest which public health has in the matter is such that materials for purifying water, like those for nourishing and healing the body, must be sold for what they are, or not at all. As we have previously stated, a reasonable time should be allowed for the withdrawal from the market of inadequate filters and unjustified professions on their behalf, and then some official action will be called for; and we trust that in this interval

the makers of filters will spontaneously render unnecessary the task of further interference. At the present time the demonstrated standard of efficient filtration appears to us to be the Pasteur filter; and it is not the least valuable of the legacies which the great man who has just passed from his work has bequeathed to humanity. There is no reason that it should remain alone in this respect. The condition of other appliances being introduced and accepted as means of combating waterborne disease is that the efficiency which Pasteur has secured be realised.

In connection with the same report, Mr. Gustav Bischof writes to us under date October 18th, respecting the experiments of Dr. Plagge in 1885 on Mr. Bischof's spongy iron filter. Dr. Plagge states that these experiments were carried out in the presence of the inventor, and showed the filter to be inefficient. While not asserting that his filter prevented the passage of micro-organisms, Mr. Bischof alleges gross carelessness on Dr. Plagge's part in the conduct of the experiments. Considering the date of this research, and the absence of exact published details, the matter must rest here so far as we are concerned.

Mr. Bischof also takes exception to the report of Dr. Sims Woodhead and Dr. Wood. He considers that it would have been better for these gentlemen to have experimented upon a somewhat larger filter, and he objects to their statement that they found little evidence to justify the statement that spongy iron does not favour the growth of low germs of life in the same way as animal charcoal and porous charcoal blocks do. The first objection can hardly be seriously sustained. In support of the second, Mr. Bischof quotes the experiments of Dr. Percy Frankland in 1886, in which the spongy iron gave a sterile filtrate for twelve days, and after a month's filtration removed 99.8 per cent. of the organisms, whereas animal charcoal after a month's filtration increased the number of organisms more than fourfold. Mr. Bischof omits, however, to state that at the time when the animal charcoal acted in this way the rate of filtration was increased to nearly double that used with the spongy iron; and that while the rate of filtration was only 15 per cent. more than that used with the spongy iron, the animal charcoal was equally found at the end of twelve days to be yielding a sterile filtrate. In any case, however, these experiments have no bearing upon domestic filters, as the materials were in each case passed through a sieve of 1,600 meshes to the square inch, that is, nearly as fine as ordinary Portland cement; and, as Mr. Bischof points out, it has not been found practicable to employ for domestic purposes materials so finely divided. Mr. Bischof also overlooks the fact that Dr. Sims Woodhead and Dr. Wood were not content with observing that the water from the two spongy-iron filters examined gave on the fourth day at least ten times as many germs as were contained in the tap water, but made special determination of the extent, if any, to which the life of a test micro-organism was inhibited by the filter, as suggested by Mr. Bischof. They found that after a suspension of the cholera bacillus had been passed through the filter, sterile water passed through it became polluted with that organism for eight days the limit of the experiments, a circumstance which shows that, so far from preventing the contamination of water, this filter is liable, when once infected, to pollute for a considerable time any pure water which may subsequently be passed through it, thereby, in the words of the report, "enormously increasing the risk of infection when any of the water used happens to have been infected."

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

We have received from Mr. J. S. Bolton, Junior House-Surgeon, the following report of a death under chloroform which occurred at the Bolton Infirmary on October 3rd. The death occurred during the operation of excision of the upper jaw by Dr. Robertson. The patient, a woman aged 43, was suffering from advanced cancer of the right maxilla. On careful examination nothing was found to contra-indicate the use of chloroform, which was administered by Dr. S. H. White, *locum tenens* House-Surgeon, at first on lint and then when the conjunctival reflex was lost, by a catheter in the

nostril attached to the efferent tube of a Junker's inhaler. At this stage the operation was commenced, but the patient winced, whereupon the catheter was withdrawn and chloroform again applied on lint, when it was noticed that the patient had ceased to breathe. Artificial respiration was at once commenced, and was kept up without avail for forty minutes. Faradisation of the phrenics and hypodermic injections of ether were used as adjuvants. At the *post-mortem* examination the heart was found to be much laden with fat, but the muscle was not involved. The rib cartilages were markedly ossified, which greatly impeded the efforts made for her recovery.

SMALL-POX AND VACCINATION IN MANCHESTER IN 1892-94 - XXII.

Dr. NIVEN, in submitting his first annual report on the health of the city of Manchester, has to record the continuance of the very serious prevalence of small-pox, which comprised 1,007 cases in the period 1892-94 the attacks notified in the three years being respectively 118, 607 and 282. The organisation in Manchester is so perfect that almost cent. per cent. of the cases found isolation in hospital, the exact number being 996, leaving only 11 attacks not removed to hospital. The disease was centred more particularly in Central and North Manchester, the locality of common lodginghouses in the former portion of the city being specially affected. The movements of tramps are credited with having to some extent contributed to the spread of small-pox, the year 1894 witnessing 11 reimportations, the means of getting revaccination performed at common lodginghouses wherein cases had arisen causing much concern by reason of their ineffectual character.

Dr. Niven would wish to see all common lodginghouse-keepers under the necessity of demanding evidence of recent vaccination on the part of all clients for shelter. He states that there seems to be a growing disposition to neglect the protection afforded by revaccination in infected households, but he does not show, apparently, how far the patients suffering from small-pox in Manchester had been revaccinated or what was the nature of primary vaccination in persons attacked.

Some very useful figures are, however, given as to the different classes of persons taking small-pox in regard of vaccination and non-vaccination. Freeing of the 996 hospital cases, Dr. Niven tells us that there were 63 deaths, a mortality-rate of 7.03 per cent.; the facts for several age-groups being as follows:

Age Periods.	Vaccinated.			Unvaccinated.			Doubtful.		
	Cases.	Deaths.	Mortality per cent. of Cases.	Cases.	Deaths.	Mortality per cent. of Cases.	Cases.	Deaths.	Mortality per cent. of Cases.
0-5	1	—	0.00	25	8	32.00	1	—	0.00
6-15	56	—	0.00	35	7	20.00	11	—	0.00
15-25	282	9	0.76	23	5	21.74	9	1	11.11
25-45	423	29	6.16	19	5	26.32	19	4	21.05
45-65	65	6	9.23	2	2	100.00	11	1	9.10
65+	5	—	0.00	1	—	0.00	1	—	0.00
All ages	841	34	4.04	102	27	26.47	52	7	13.31

From these data we see that up to the age of 15 years the vaccinated sufferers were proof against death by small-pox; that those doubtful as to vaccination were in like happy case, their vaccination, if ever performed, having apparently faded away. At no age group is the mortality among the vaccinated as high as 10 per cent., whilst three-quarters of the mortality among the unvaccinated occurs in persons under 25 years. Taking all ages together, the death-rate in the unvaccinated was to the vaccinated at 6 to 1. It is the oft-repeated tale of disaster in the unprotected class of sufferers.

Had the rate of mortality in the vaccinated class been identical with that in the class of unvaccinated patients, the deaths occurring would have been not 34 but 222.

Dr. Niven reports that in 1894 there were 63 cases in which the diagnosis of small-pox was erroneously made by the certifying practitioners; in other instances small-pox was in question, though not suspected; and in view of the evidence as to the mistaken diagnosis of medical men in the matter, Dr. Niven deems it an urgent duty of medical schools to provide instruction in the diagnosis of small-pox, the necessity for practical acquaintance with infectious diseases being made obligatory at examinations.

PROPOSED HOSPITAL FOR INFECTIOUS DISEASES NEAR DUBLIN.

THE sanitary authorities in Dublin are promoting a scheme for a new hospital for infectious diseases, to be erected outside the city. The institution is to be erected and supported by a levy on the rateable property of the associated Poor-law unions, and in the event of an epidemic, temporary hospitals may be established. At the conference which was held it was stated that the cost of maintenance would be about £10,000 a year. The proposal has already brought out much opposition, and it is, we are informed, not at all likely that it will be carried out in its present form. Everyone admits that it is advisable to remove small-pox or cholera cases from the city; but the ratepayer looks with alarm upon a scheme which will add £10,000 a year to the rate burden to meet emergencies which may not arise for many years. The general feeling is, it is stated, fairly expressed by the resolutions of the Dublin Sanitary Association, which are as follows:

1. The scheme in question would entail a cost altogether out of proportion to its probable beneficial effect upon the public health.
2. It has not been shown that the infection of any infectious fever, except small-pox, crosses wide air spaces, and so the proposed legislation would in effect have reference to one disease only, and that a disease altogether preventable by periodical vaccination.
3. The proposed scheme would very injuriously affect the interests of the great medical school of Dublin by interfering with the teaching of fever and its treatment by the first clinical physicians in the city and by throwing obstacles in the way of students learning fever and its treatment.
4. The dislike of patients to go and of parents to send their children to hospitals situated at a distance, and specifically called "isolation" or "fever hospitals," would lead to concealment of infectious disease and to its consequent spread in the homes of the poorer classes.

OPENING OF THE MEDICAL SCHOOLS:

MEATH HOSPITAL, DUBLIN.

PROPOSED PATHOLOGICAL INSTITUTE.

THE introductory address at the Meath Hospital, Dublin, was delivered by Dr. E. Lennon, one of the physicians. In the course of his remarks, he advocated the establishment of a central pathological institute in Dublin, and suggested that this work might well be undertaken by the Royal Academy of Medicine. The Government had granted aid for the furtherance of medical investigation in other portions of the kingdom, and he did not see why the same should not be extended to Ireland. He calculated the cost at £2,000 for the first year, and £1,300 a year subsequently. He thought the universities, licensing bodies, and the corporation ought to subscribe to support such a project. There would be a further income from fees from students, from the examination of animals, and from special courses in bacteriology.

Dr. W. G. Smith (President of the College of Physicians) who presided, thought the forecast somewhat utopian.

Sir Thornley Stoker, President of the College of Surgeons, thought the key to the position lay in the hands of the University of Dublin. It would be delightful to believe that the numerous opposing bodies would co-operate in the somewhat Arcadian manner suggested by Dr. Lennon, but his experience led him to think that such a thing was not probable.

Sir W. Stokes believed that with an earnest effort on the part of the profession, the bodies indicated as bodies that should co-operate in this great philanthropic purpose would see the wisdom of uniting for so great and glorious an object. A vote of thanks to the lecturer terminated the proceedings.

ST. VINCENT'S HOSPITAL, DUBLIN.

THE FIFTH YEAR.

Mr. R. T. Tobin delivered the introductory address at this hospital. Speaking of the fourth and fifth years work of students under the new scheme, he pointed out that in his opinion the student did not spend his time to advantage. In place of being relegated to the hospital for his training during the second period, he was obliged to attend the schools for theoretic lectures in medicine and surgery, and for examinations in connection with these lectures, and these so dominated his views that he spent his time in hospital, not watching the changes in his patients, but on the look-out for ready-made answers to questions. If urged to make records of cases he did so reluctantly, for he knew that from an examination point of view it did not pay, and if towards the conclusion of his course he was offered the position of resident pupil in a large and busy hospital, he often refused it because he was going in for his "final," and, of course, the one thing essential was to pass. His medical education, therefore, notwithstanding a large amount of hospital attendance, was literary rather than practical. Mr. Tobin urged that hospital teaching should be made a true education by relegating students altogether to the hospitals during the second period of study. A vote of thanks was passed to the lecturer for his address.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held on October 23rd; Mr. T. HOLMES, Vice-President, in the chair.

A letter was read from the Secretary of the Royal College of Surgeons, in reply to a letter from the Secretary of the Fellows Association, forwarding a copy of a resolution in reference to the conduct of the business at the meeting of Fellows on July 11th. The Council desired to point out that the meeting of Fellows was held and conducted in strict accordance with the regulations appertaining to the meetings, and that, as there were no notices of motion on the agenda, no discussion could properly take place, the regulations of the meeting requiring previous notice of twenty-one days.

After some discussion it was decided to reply in the form of the following resolutions, which were proposed, seconded, and unanimously carried:

1. That the Committee of the Association of Fellows regrets to learn that, in the opinion of the Council, the last meeting of Fellows "was conducted in strict accordance with the regulations appertaining to these meetings."
2. That this regret is based upon the belief of the Committee that when the regulations for the Fellows' meetings were first drawn up it was intended by the framers to give the Fellows the opportunity without definite notice (a) of making any observations necessary on the minutes, (b) of asking for any further information desired from the Council on any topic contained in the agenda, (c) of giving notice of motion for a future meeting, (d) of discussing any of the subjects dealt with in the Council's report.
3. That if the present regulations do not provide for the opportunities referred to in the preceding resolution, the Committee would respectfully suggest to the Council that the regulations should be modified in the direction indicated.
4. That a copy of the foregoing resolutions be forwarded by the Honorary Secretary to the Secretary of the College for presentation to the Council at its next meeting.

A communication was read from the Secretary of the Society of Members, and a resolution was adopted to the effect that it is undesirable that the Association of Fellows should take any conjoint action with the Society of Members in regard to their resolutions which the latter body proposes to bring forward at the meeting of the College on November 7th.

It was also unanimously agreed that the question in regard to the admission of women to the examinations at the College was not one upon which the Association as an association was called upon to express an opinion. It was further decided not to bring forward any resolution on behalf of the Association at the ensuing annual meeting.

A resolution was passed fixing the annual general meeting of the Association for Wednesday, November 13th, 1895.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary.*

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

PERTSHIRE BRANCH.—The winter meeting of this Branch will be held in the Station Hotel, Perth, on Friday, November 1st, at 3.45 P.M., under the presidency of Dr. Leigh Hunt, who will deliver an address. The ordinary business of the Branch, election of officers and members, treasurer's statement, etc., will then be taken. The usual dinner will follow in time to permit of country members returning home by the evening trains.—A. R. URQUHART, *Honorary Local Secretary, Perth.*

SOUTH-WALES AND MONMOUTHSHIRE BRANCH.—The next meeting of this Branch will be held, by the kindness of Dr. Pringle, at the County Asylum, Bridgend, on Tuesday afternoon, November 16th. Members are requested to give notice of communications to be brought before the meeting before November 3rd, to D. ARTHUR DAVIES, M.B., Swansea.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The first meeting of this District will be held at the London Temperance Hospital, Hampstead Road, N.W., on Thursday, October 31st, at 4 P.M. Sir W. O. Pridmore will preside. Dr. W. E. Cleveland will read a paper On the Prophylactic Clothing of the Body, chiefly in Relation to Cold. The District Committee will meet at 3.45 P.M.—HUGH WOODS, *Honorary Secretary.*

SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT.—The next meeting will be held at the County Hospital, Guildford, on Thursday, October 31st, at 4 P.M.; Dr. J. P. A. Gabb, of Guildford, in the chair. Dinner at the White Lion Hotel at 5 P.M.; charge 6s., exclusive of wine. All members of the South-Eastern Branch are entitled to attend, and to introduce professional friends. Agenda: Arrangements for next meeting. Papers: Mr. Stanley Boyd (London): Some Surgical Cases of General Interest. Dr. Montague Murray (London): Hydrochloric Acid in the Diagnosis and Treatment of Chronic Gastric Disorders. Members desirous of exhibiting or reading notes of cases are invited to communicate at once with the Honorary Secretary, ALEX. HOPE WALKER, The Common, Cranleigh.

STAFFORDSHIRE BRANCH.—The twenty-second annual general meeting will be held at the North-Western Hotel, Stafford, on Thursday, October 31st, at 4.30 P.M., when an address will be delivered by the President-elect, Dr. G. Reid. Members and friends will dine together at 6.30 P.M.—G. REID, *General Secretary, Stafford.*

NORTH OF IRELAND BRANCH.—The autumn meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, October 31st, 1899, at 12 noon. Gentlemen who wish to read papers, show patients, or bring any other business before the meeting, will kindly communicate, as early as convenient, with JOHN CAMPBELL, M.D., F.R.C.S., Honorary Secretary, 21, Great Victoria Street, Belfast.

SOUTHERN BRANCH: SOUTH EAST HANTS DISTRICT.—The next half-yearly meeting of this District will be held at the Medical Library, 5, Pembroke Road, Portsmouth, on Friday, November 1st, at 4 P.M. Agenda:—Cases: Pityriasis Rubra; Eye Cases; Case for Diagnosis; Mycosis of Pharynx, etc. Anthropological Specimens: Skulls from Australia, New Zealand, etc. Pathological Specimens: Dermic Horn; Bowel from Fatal Case of Carbolic Acid Poisoning. Microscopic Specimens: Epithelioma of Esophagus; Mycosis of Pharynx. Communications: The Influence of Large Doses of Arsenic on Chorea, J. R. Robertson, M.D. A Few Important Details in Aseptic Surgery, H. E. Counsell, F.R.C.S. Notices of Motion: To be proposed by Dr. Pearce, and seconded by Mr. Lord: "That this meeting recommends the Bill of the Parliamentary Bills Committee of the British Medical Association relating to midwifery nurses and their registration, and cordially endorses the vote passed at the annual meeting of 1898 in support of Mr. Lawson Tait's amendment—namely, 'That we the members of the British Medical Association, while

anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act of 1869 as now existing." To be proposed by Dr. Pearce and seconded by Dr. Lord: "That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties, and to devote a portion of the income and funds of the Association for these purposes."—C. C. CLAREMONT, *Honorary Secretary, 57, Elm Grove, Southsea.*

BATH AND BRISTOL BRANCH.—A special meeting will be held in the Medical Library, University College, Bristol, on Wednesday evening, October 30th, at 7.30, Carey Coombs, M.D., President. Agenda of rules:—Dr. Michell Clarke will move the adoption of the following rule: "That papers shall not exceed twenty minutes in delivery, and that each subsequent speaker shall be limited to ten minutes." Dr. Markham Skerritt will move to alter Rule vi as follows: "After 'year' to insert 'always' excepting that no member shall so retire who has not served upon the Council for the full term of four years." The following communications are expected: F. Watson Williams, M.D.: The Thyroid Gland and Graves's Disease. J. G. Swayne, M.D.: Cases of Induced Premature Labour in certain Diseases of the Mother not obstructing Delivery. George Parker, M.D.: 1. Perforation of Appendix in Enteric Fever. 2. Perityphilitis; Portal Pyæmia. J. Mitchell Clarke, M.D.: 1. Sequel to Case of Trophing to relieve Symptoms of Cerebral Tumour. 2. Case of Birth Palsy in which an Operation was performed.—J. MICHELL CLARKE, Clifton, W. M. BRAUMONT, Bath, *Honorary Secretaries.*

MALAYA BRANCH.

THE usual monthly meeting of this Branch was held in the Raffles Museum, Singapore, on July 6th; the VICE-PRESIDENT (Dr. Simon) in the chair.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

Representative on Council of Association.—The Hon. SECRETARY read a communication received from the General Secretary, asking the Branch to appoint without delay a representative to act upon the General Council of the Association. Dr. SIMON proposed that Dr. Ellis be elected the representative of the Branch. This was seconded by Dr. LEASK, and passed unanimously.

Notice of Motion.—Dr. LIM BOM KENG gave notice that at the following meeting he would move:

That this Branch of the British Medical Association do consider the proposed Regulations for Registration of Births and Deaths with special reference to Clause 13, and lay their views before the Government.

Dr. JANSZ seconded the motion.—Dr. MIDDLETON considered that as the subject was of great importance, a whole evening be devoted to the question. He accordingly proposed that a special meeting be held for this purpose.—Dr. LIM BOM KENG seconded the proposal, which was put to the meeting and carried. It was decided to hold a special meeting upon July 20th.

Communications.—Dr. CROUCHER read notes of some cases of Acute Dysentery treated with Sulphate of Magnesia. Dr. LEASK strongly recommended treatment with sulphate of magnesia in inflammatory cases with high temperature and abdominal pain. Both ipecacuanha and sulphate of magnesia acted strongly upon the liver, hence their beneficial effect. When small specks of blood were seen in the motions, Dr. LEASK prescribed rectal injections of solutions containing nitrate of silver. Dr. SIMON considered that the action of sulphate of magnesia was due to its relieving the congestion of the lower bowel, and by clearing out its contents. He advocated nitrate of silver enemata with or without ipecacuanha in certain cases. Dr. LIM BOM KENG was of opinion that the remedy in question greatly relieved tenesmus. The indication for its use was the frequency of the motions. If too frequent it should not be given. It acted best in inflammatory cases, while ipecacuanha did best in serous discharges. Dr. FOWLER supported the idea that it acted by emptying the bowels as well as by its action on the liver. Surgeon-Captain GREGG advocated more extended treatment by local applications, such as injections of ipecacuanha with opium. Dr. HIGHTER spoke of the benefits to be derived from sulphate of magnesia in inflammatory cases. In chronic cases enemata of nitrate of silver or salicylate of soda solutions were of great value.—Dr. FOWLER made some remarks upon Dietetics in the Tropics. In the discussion which followed, Drs. LEASK, HIGHTER, BOM KENG, and Surgeon-Captain GREGG joined.

Votes of Thanks.—Votes of thanks to Drs. Croucher and Fowle terminated the meeting.

DORSET AND WEST HANTS BRANCH.

The autumn meeting of this Branch was held at Boscombe on October 16th, Mr. G. H. W. PARKINSON (President) in the chair. Fifty-eight members and visitors were present.

Election of Officers.—The following were elected office-bearers for the ensuing year: *President:* Mr. William Randall of Marden Newton. *Vice-Presidents:* Mr. Thomas Frederick Gardner of Bournemouth, and Mr. William Henry Williams of Sherborne. *Honorary Secretaries and Treasurers:* Dr. William Vawdrey Lush of Weymouth, and Mr. Charles H. W. Parkinson of Wimborne.

Next Meeting.—It was resolved that the May meetings should be held at Sherborne.

British Medical Benevolent Fund.—A donation of five guineas was granted to the British Medical Benevolent Fund.

Address.—Dr. Radcliffe Crocker delivered an address on the Treatment of Inflammations of the Skin.

Communications.—The following communications were presented: Mr. KINSEY MORGAN, A patient with Congenital Exophthalmos, Enlargement of Right Half of Head and Right Forearm.—Dr. RAMSAY (1) Uterus removed for Protrusion; (2) Specimen showing new method of Wiring Patella.—Mr. VERNON, A case of Fractured Olecranon treated by Suture.—Dr. EVANS, Patient with good recovery after Suture of Patella.—Dr. LAURIE (1) Removal of a large Ovarian Tumour; (2) A case of Oophorectomy for relief of Reflex Symptoms.—Mr. CHARLTON and Dr. EVANS, A case of Castration for Prostatic Diseases.—Dr. RANSOME, The Act of Coughing.

Dinner.—The members and friends dined together at the Hotel Burlington.

SPECIAL CORRESPONDENCE.

PARIS.

Appointment of M. Pasteur's Successor.—*The Constitution of the Pasteur Institute.*—*The Intoxicating Principle in Alcoholic Beverages.*—*Paris Water Supply.*—*Funeral of Baron Larrey.*

THE Council of the Pasteur Institute—composed of M. Joseph Bertrand, M. Jules Simon, Vicomte Delaborde, MM. Wallon, Brouardel, Duclaux, Grancher, Baron Alphonse de Rothschild, MM. Magnin, Christophle, and Roux—have unanimously elected Dr. Duclaux Director of the Pasteur Institute, and Dr. Roux Sub-Director. M. Vallery-Radot is proposed as member of the Council as representative of the Pasteur family. The Assembly which controls the administrative council will consider these propositions.

The Assembly is composed of thirty members. The Pasteur Institute is a private not a Government institution; it is therefore self governed, but, being recognised as "of public utility," it is under State control and is attached to the Ministry of the Interior. The members of the Assembly are those who helped to found the Institute; the Assembly elects the council of administration and controls its accounts. The receipts budget is as follows: The interest on what remains of the public subscription, which amounted to £18,000, has now increased to £160,000; £80,000 was spent on the ground bought for the Institute and in building. From £500 to £1,500 was granted by the Minister of Agriculture in recognition of the service rendered by the anthrax vaccine, by the treatment of swine fever, and by the supply of tuberculin and mallein. A subvention is granted the Minister of Public Instruction to pay the salaries of such of the Institute staff as were formerly attached to Pasteur's Laboratory, which formed part of what is called the "Hantes Etudes." Certain profits are made by the sale of the anthrax vaccine, and others sold at a very low price to veterinary surgeons. M. Pasteur, M. Roux, and M. Chamberland relinquished all right to participate in these profits, and they realise for the Institute an income of £800. The fees paid by the pupils who attend the lectures of

the Institute are also paid into the Institute treasury. Dr. Roux's antidiphtheric service is annexed to the Pasteur Institute, but has a distinct budget. This service is organised at Garches, on the estate given by the Government to M. Pasteur for the purpose of carrying on his researches on rabies. It is managed by Dr. Roux, under the double control of the Council of the Pasteur Institute and of the Minister of the Interior. Its revenue is furnished by the interest on the sum realised by a public subscription, and by a Government grant amounting this year to £3,200. Hospitals, the army, and public charitable societies are supplied with serum gratuitously. The public pay 2s. 6d. a bottle; the profits of the sale are applied to the purposes of the Institute. The services at the Institute are as follows: Practical services, consisting of inoculations, etc.; the lectures in this service are given by Dr. Roux and Dr. Metchnikoff. The pupils are of two classes, "hearer" and "workers," who are allowed to work in the laboratories. The research laboratories are placed at the disposal of investigators, whose communications are published in the *Annales de l'Institut Pasteur*. The chiefs are—M. Duclaux for biological chemistry; M. Grancher, M. Charrin, and M. Chantemesse for rabies; M. Chamberland for microbial vaccinations and practical applications. There is a morphological laboratory under the direction of M. Metchnikoff, and a technical one under M. Roux. M. Nocard, Professor at Alfort Veterinary School, directs a veterinary service annexed to the Institute. M. Duclaux is Professor at the Faculté des Sciences. The course of lectures he previously gave at the Sorbonne are now held at the Pasteur Institute, where the Sorbonne pupils follow him. The Institute was founded in 1888, and retains its constitution and characteristics notwithstanding the death of Pasteur. His pupils will carry on the work.

At a recent meeting of the Academy of Medicine M. Daremberg stated that pure alcohol at 10° is less toxic than impure alcohol, such as *eau de vie*, and above all old *eau de vie* made from wine at 10°. *Eau de vie* made from wine at 10° is less toxic than wine at 10°. *Eau de vie* is in fact wine purified. The intoxicating element in wine is not present in the part distilled, but in the residue. Red wine is more intoxicating than white wine; the latter is produced by the fermentation of the juice of grapes, whereas the red wine is the product of the fermentation of the juice, skin, and pips of grapes. It is the bitartrate of potassium which constitutes the special intoxicating principle of red wine. French beer contains 5 per cent. of alcohol; 50 cubic centimetres injected into the veins of a rabbit produced no result. The different varieties of cider, on the other hand, were generally very intoxicating. M. Daremberg injected alcohol into the veins of rabbits rendered tuberculous three days previously. Alcohol chemically pure did no harm, but *eau de vie* and wine killed them rapidly. The wisdom of giving alcohol to tuberculous patients is therefore doubtful. The toxic quality of alcoholic drinks is not thoroughly evident when there is neither kidney nor liver trouble. Healthy subjects easily eliminate these toxic substances, which even under certain circumstances may be valuable as occasional stimulants.

At a recent meeting of the Municipal Council a resolution was passed that the administration of the Municipal Council be called upon without delay to lay before the Council the plans for bringing to Paris spring water in sufficient amount to satisfy the domestic needs of the capital until 1900; to suggest means of preventing or regulating the use of spring water in water closets; to hasten the construction of the filtering and decanting tanks for Seine water below Paris. It was also resolved that the administration be called upon to protect the Seine from contamination from the Corbell as far as Choisy le Roi waterworks. The Council, in accordance with M. Lévrand's proposition, calls upon the administration to make trials of different means for the limitation of the supply of spring water during the exceptionally hot summer weather; to construct without delay fresh reservoirs; to hasten the execution of the schemes proposed for giving Paris additional water supplies; also to hasten the carrying out of the system of double canalisation for bringing Seine water and spring water into the Paris houses, each system of pipes being entirely separate.

The funeral of Baron Larrey took place on Friday, October 18th. Four funeral orations were delivered: one by a mem-

ber of the Academy of Sciences, another by a member of the Academy of Medicine, a third by the general inspector of the Health Society, the fourth by a professor of the Val de Grace. The religious ceremony took place at the Val de Grace, and the body was afterwards placed in the family mausoleum at Père la Chaise.

FLORENCE.

Midwives in Italy.—Exhumation of the Remains of Giuliano and Lorenzo de' Medici.—Excavations in Florence.—Grandi, the Child Strangler.—News.

In addition to a National Federation of Midwives there are at least seven societies of midwives in Italy, all of which are sending representatives to the third National Congress of Midwives. Among the subjects proposed for discussion are the proposed abolition of midwives and the subversion of social order. The connection between the two heads of this subject will not be obvious except possibly to midwives. The status and duties of a midwife are well defined in the Official Sanitary Regulations:

No one shall attend a woman in childbirth who has not completed her two years' course of studies at a maternity hospital, passed her examinations, and taken the diploma. The diploma must be registered at the office of the commune in which she lives. The midwife must call a doctor if the labour or puerperium is abnormal. In the absence of the doctor she must advise the Sindaco (Mayor) of the abnormality. If she has attended a case of puerperal fever she must within five days disinfect herself, and not attend another case without the sanction of the sanitary officer. She must keep a register of births. She must attend the poor gratuitously. She must wash her hands frequently in boracic acid, always wash the genitals before making an exploration, and perform the latter as seldom as possible. After the birth she must examine the placenta, irrigate the vagina with solution of boracic acid, and maintain great cleanliness for a period of at least eight days. The infant must be washed with tepid water that has been boiled, and its eyes bathed with antiseptic solution.

Prior to the second half of last century the attendance on childbirth appears to have been exclusively in the hands of women, and one of the few books for the instruction of midwives in the performance of their duties was by Scipione Cicerario. Besides giving full instructions for the performance of Caesarean section, this work treats of the origin of monsters, on the influence of the stars on pregnant women, and on conception by devils. Systematic instruction in the mechanism of labour was organised in various Italian towns, notably Bologna, Milan, Turin, and Florence in the latter half of the century, and was conducted by means of models of the pelvis and dummy infants, and by demonstrations on the cadavers of women who had died in childbirth. At that period the qualifications of midwives varied greatly in different parts of Italy. Thus, some were requested only to watch for abnormalities, and inform the doctor of them. Others were required to perform Caesarean section, and an edict was issued in Sicily whereby neither barbers nor midwives were allowed to attend women in labour unless they were capable of performing Caesarean section. In other parts, the chief qualification was a knowledge of reading and writing, so that the midwife might administer the sacrament in case of necessity. An opuscle was written about this time by Roncalli Perolini on a method of performing baptism *in utero* by means of a bladder of water, a siphon, an intra-uterine tube, and a vaginal speculum. With the change in requirements the mortality from puerperal fever has fallen enormously. The modern Italian midwife occupies a definite position, and seems to perform her functions without much friction. She is neither doctor nor monthly nurse, but is called upon to conduct normal labour with all the precautions dictated by our present day knowledge, and to recognise and summon skilled aid in case of departure from the normal.

On October 2nd, in the presence of Professor del Lungo, Cav. Pichi, Monsignore Athilio Giovannini, Professor Villari and others, the tomb reputed to contain the mortal remains of Lorenzo and Giuliano de' Medici was opened. Two skeletons were revealed which bore evidence in support of the accuracy of the current report. Within the tomb two wooden coffins were found, one on the top of the other. The first was short, and in a good state of preservation; the second was longer, and mouldering. The cover of the upper one bore the following inscription, roughly written in ink: "Giuliano di Pietro di Cosimo de' Medici." Within the coffin was a skeleton, with the femora and tibia flexed on the

thorax. The cranium bore marks of two injuries inflicted with a cutting instrument; traces of another incised wound were found on the tibia. Giuliano, as will be remembered, fell a victim to the Pazzi conspiracy, as narrated by Machiavelli in his history of Florence. In the second coffin the skeleton was reduced to pulp; but Lorenzo is known to have been buried with his brother Giuliano, and the chief lines of the cranium were seen to correspond with those of his portrait; besides, there was a bony excrescence beneath the nose which Lorenzo is known to have had. The two crania were photographed. Thus the Florentines may rest content that they possess the mortal remains of two illustrious members of the most illustrious family connected with Florence at the time of the renaissance of arts and letters in Europe. The name Medici recalls the early connection of the family with the profession of medicine before it rose to eminence in the political, mercantile, and social world.

Excavations conducted in connection with the renovation of the archiepiscopal palace in Florence have revealed the remains of an old Roman thermal establishment in the square between the palace and the baptistry. The sanitary reforms in the centre of Florence have been the means of bringing to light extensive Roman remains at a depth of two or three metres beneath the surface.

The child strangler, Grandi, has just completed his term of twenty years' penal servitude. His head is of the characteristic criminal type, and he will pass the remainder of his life within the precincts of a lunatic asylum.

The information that a woman bitten by a sow near Lienna has been sent to the Istituto Antirabbico at Rome reminds us that Italy, untrammelled by the clamour of irresponsible faddists, is ahead of us in the practical application of some of the indications afforded by recent scientific research.

Dr. Benedetto Cimino complains that while Professor Maragliano is allowed to experiment largely with his anti-tuberculous serum at Genoa, he himself is not allowed to introduce his anticarcinomatous serum into Italy. No new remedy may be used in Italy until its employment has been sanctioned by the Direzione Generale di Sanità.

CORRESPONDENCE.

THE MALARIA PARASITE.

SIR.—In most of the recent correspondence on the subject of the malarial parasite sufficient attention has not been paid to the variability of its distribution in the blood. In fatal cases it is the common thing to find that whilst in one organ, that is the brain, over one-third of the red corpuscles contain intracorporeal bodies, in other organs only a small proportion contain them, though in the case of the spleen there may be many pigmented leucocytes. In these cases very few intracorporeal bodies, or perhaps none, may be found in the peripheral blood when examined before death. Dr. Thin records a case in which the intracorporeal bodies were found only in the intestinal vessels.

In cases which were similar but not fatal, though the intracorporeal bodies may not have been found in the blood, pigmented leucocytes are so abundant in the peripheral blood that it is clear that the intracorporeal bodies must have been present in some part of the body.

It seems to be generally assumed though not definitely stated that a certain proportion of the blood corpuscles are attacked and that their distribution is determined solely by mechanical principles. Instead of this it seems to be the case that the blood corpuscles in certain organs are attacked or that the attacked corpuscles accumulate in certain organs of the body whilst only stray ones are found in the general circulation.

Though I am quite aware that many competent observers have found them in the great majority of cases diagnosed as malarial, several points have to be considered in this connection:

1. Cases of acute malaria arriving in England must be of exceptional severity to have lasted so long.
2. Malaria has no definite physical signs and symptoms beyond those of pyrexia with longer or shorter intermissions, and these symptoms are common in the tropics from

filariasis, anaemia, chronic enlarged spleen, etc., without any sign of acute malaria being found after death. If all cases in which any of these conditions are found are excluded from the list, many cases of malaria will also be excluded with them, and if only those in which the parasite is found be included (as I believe is done in some places), there will be no failures at all.

3. Many of the slighter cases of malaria do not require treatment as in-patients, and consequently in a crowded hospital, where only cases of urgency are taken in only the more severe forms will be examined. In the blood of these the plasmodia will be more frequently found than in the ordinary cases.

As regards the existence of the intracorporeal bodies, there can be no doubt that they are both numerous and readily seen in certain organs in every fatal case.

The opposition is, I feel sure, to some extent caused by the too dogmatic statements made as to their frequency. Men are constantly told that these intracorporeal bodies are always present, and again that a child may recognise them. Ordinary observers, after examining the blood in several cases, and seeing what they know to be vacuoles, crenated corpuscles, blood platelets, etc., which closely resemble the illustrations of the nonpigmented intracorporeal bodies, fail to see the true parasite, and naturally entertain doubts as to its very existence. In many of these cases I believe they did not see it because it was not present.

If, on the other hand, it were clearly stated that to find the bodies in an ordinary transient attack of malaria in the small quantity of blood that is examined, is only rather more probable than to find filaria in the daytime in a case of filariasis, we should have a truer representation of the usual experience in British Guiana at any rate.—I am, etc.,

C. W. DANIELS, M.B. Cantab.
British Guiana Medical Service.

Crossington, Oct. 8th.

ARE COLLIERIES EXEMPT FROM CANCER?

Sir,—In answer to the above query, I think it may be affirmed that colliers are relatively less liable to cancer than almost any other class of the community. The following considerations bear out this statement. There are few districts where cancer is less prevalent than in the great colliery centres of Derbyshire, South Wales, Durham, and Lancashire. Among the English counties having the highest cancer mortality, the colliery counties are conspicuous by their absence. Of the forty places in England and Wales where the highest cancer death-rates are known to prevail, there is not a single colliery centre.

At the same time it should be remarked that in mining districts like Cornwall, and in great quarrying centres like North Wales, the cancer mortality is as low as in the colliery districts. Moreover, in most industrial centres outside colliery and mining spheres the cancer mortality is remarkably low.

The great proneness of the agricultural community to cancer contrasts markedly with the foregoing. Roughly speaking, cancer is more than twice as prevalent in the agricultural districts than it is in the colliery, mining, and industrial centres. Of 250 men with cancer under my observation, 14 were agricultural labourers but only 1 was a collier.

As a rule, the cancer mortality is lowest where the struggle for existence is hardest, the density of population greatest, the tubercle mortality highest, the average duration of life shortest, the general mortality highest, and where sanitation is least perfect—in short, among the industrial classes; whereas, among the wealthy and well-to-do—where the standard of health is at its best and life is easiest—and among the agricultural community, there the cancer mortality is highest.

In London and its vicinity, where the wealth of the nation is clothed, there the cancer mortality is highest; and it is a significant fact that the mortality is highest of all in those parts of the metropolis where the well-to-do most abound. The average cancer mortality for all London in 1894 was 1 in 1,465; in the great industrial centres of the East End the mortality was as follows: Bethnal Green, 1 in 2,886; Shore-ditch, 1 in 2,482; Stepney, 1 in 2,341; St. George-in-the-East, 1 in 2,245; Poplar, 1 in 2,173; Mile End, 1 in 2,209. In these centres the cancer mortality is as low as in the colliery and

mining districts. What a contrast with the foregoing is well-to-do, easy-going Richmond, with a cancer mortality of 1 in 960! It is high time that such questions should be thoroughly investigated.—I am, etc.,

Preston, Oct. 15th.

W. ROGER WILLIAMS.

Sir,—In the annotation in the BRITISH MEDICAL JOURNAL of October 19th, under the heading "Are Colliers Exempt from Cancer?" allusion is made to the immunity from cancer which is believed by Mr. T. Law Webb, of Ironbridge, to exist among the colliers of Shropshire, and a desire is expressed that surgeons practising in other colliery districts should state their experience on this point.

For the past fifteen years I have been practising as a colliery surgeon at Haydock, Lancashire. The population of this place was at the last census 6,535. Probably at least three-fourths of the working male inhabitants are employed in coal mines. My general recollection as a practitioner had certainly given me no reason to believe that cancer was unusually rare among colliers. However, as medical officer of health for the urban sanitary district of Haydock I have the death returns of the district registrar for a number of years back. I have taken the trouble to go through these returns for the ten years 1885-94, and have tabulated the deaths certified as due to cancer or malignant disease. The result is as follows:

Year.	Estimated Population.	Sex.	Age.	Condition of Life.	Cause of Death.
1885	6,127	M.	75	Overlooker at colliery	Cancer of stomach.
1886	6,191	M.	48	Coal miner	Epithelioma of buttock.
		M.	77	Coal miner	Cancer of stomach.
1887	6,255	M.	70	Colliery labourer	Malignant disease of elbow.
		M.	62	Farmer	Cancer of stomach.
		M.	58	Coal miner	Cancer of stomach.
1888	6,330	F.	61	Greener	Cancer of stomach.
		F.	67	Widow of colliery engine-winder	Cancer of uterus.
		F.	59	Wife of plumber	Cancer of uterus.
		F.	65	Widow of labourer	Malignant disease of bowel.
1889	6,366	M.	31	Coal miner	Cancer of rectum.
		M.	63	Coal miner	Cancer of rectum.
		F.	60	Wife of coal miner	Cancer of stomach.
1890	6,452	F.	58	Wife of coal miner	Malignant disease of uterus.
		F.	58	Wife of coal miner	Cancer of liver.
		M.	75	Pony-tender in coal mine	Cancer of liver.
1891	6,505	M.	47	Police constable	Malignant disease of intestine.
		M.	76	Farm labourer	Cancer of liver.
		F.	67	Widow of coal miner	" "
1892	6,624				" "
1893	6,697	M.	68	Joiner and carpenter	Malignant disease of stomach.
		F.	48	Widow of colliery engine-winder	Cancer of liver.
		M.	63	Coal miner	Malignant disease of rectum.
		F.	54	Widow of canal boatman	Malignant disease of uterus.
		M.	55	Coal miner	Malignant disease of liver.
1894	6,770	M.	50	Coal miner	Malignant disease of stomach.
		F.	17	Daughter of coal miner	Osteo-sarcoma of femur.
		F.	57	Widow of coal miner	Malignant disease of rectum.

Several "non residents" who died from cancer at Haydock Lodge Lunatic Asylum have not been included.

It will thus appear that in the ten years 1885 to 1894, 27 deaths were registered as due to cancer and malignant disease, including 15 males and 12 females, and that of the 15 males, 11 were employed in coal mines. In so far, then, as the district of which I have special knowledge is concerned, there does not seem to be any ground for believing that colliers enjoy immunity from cancer. However, the population of this district, as a whole, apparently have some degree of relative immunity, for the average yearly population on the ten years in question being 6,447, the annual average mortality from cancer has been 0.418 per 1,000, whereas for the whole of England and Wales for the ten years 1881 to 1893 (the annual report of the Registrar-General for 1894 being not yet available) the average annual mortality from cancer was 0.638 per 1,000. Whether this relative immunity may be due in any degree to the large proportion of workers in coal mines among the population, and any circumstances attending their calling, is more than I can undertake to say.—I am, etc.,

Haydock, St. Helen's, Oct. 21st.

T. E. HAYWARD.

THE INTRODUCTION OF SURGICAL ANÆSTHESIA.

SIR,—I regret to see, at page 915 of the *BRITISH MEDICAL JOURNAL* of October 12th, a reflection cast on the mode in which Mr. Liston received the first intimation from America of the great discovery of anæsthesia. There is no fault to be found with Sir Russell Reynolds's graphic account of the first operation done by Mr. Liston under anæsthesia in England. It gives a good specimen of Mr. Liston's manner both in speech and action; but I find in it no "grudging utterance" whatever. If Mr. Liston did bear any grudge to anyone or anything in the matter, it must soon have left him, for he immediately wrote an enthusiastic letter to his friend Professor—afterwards Sir James—Simpson, sending him at the same time an instrument for giving ether, the anæsthetic first used. This was, I am very sure, the first intimation we had in Edinburgh of the grand discovery, for if Simpson had heard of it earlier he was not the man not to have gone in for it at once. He lost no time in giving the ether a trial, and it was arranged that Mr. Naysmith, the well-known dentist and surgeon, would extract a tooth under it, and Dr. James Duncan do an operation—I think the removal of a leg in the Edinburgh Infirmary. I was then Simpson's colleague, and as he was unfortunately called away after the arrangements were made, I had to give the anæsthetic first to Mr. Naysmith's patient, and next day to Dr. Duncan's. In both cases the success was perfect.

I quite agree with what is said about the way in which the discovery was received by many members of the profession and by others; but it is not fair that Mr. Liston's well-known mode of speech should be taken advantage of to cast a slur upon his generosity and good feeling.—I am, etc.,

Currie, Midlothian, Oct. 16th.

GEORGE S. KEITH.

"CISTERN AND THE CONSTANT SERVICE."

SIR,—In connection with your remarks on the above subject in the *BRITISH MEDICAL JOURNAL* of October 19th, I venture to ask you to print for the information of your readers the following resolution, which after full discussion was passed *nem. con.* by the large meeting of metropolitan medical officers of health:

That this Branch is of opinion that in London storage cisterns should be retained for domestic purposes in occupied dwelling-houses supplied with water under the constant service system, and that a draw-off tap should be affixed to the rising main for the supply of water for dietetic uses.

You are aware that considerable districts in London are still supplied on the intermittent system, and it is probable that in such districts the water is not "on" for more than one hour in the day. But the houses being possessed of storage cisterns, there never need be any lack of water, assuming the sufficiency of such cisterns. In the course of the recent inquiry into the causes, etc., of the water "famine" at the East End, two hours was mentioned as the shortest duration of the daily supply of water—one hour in the morning and one hour in the evening. It must be manifest, therefore, that had domestic storage been in existence, there would have been no "famine." There is always a liability to the water being turned off, for a longer or a shorter time, in districts under constant service, and when this happens houses without storage become insanitary, and much inconvenience arises. The health officers of the metropolis, therefore, taking the facts into consideration, came to what I think to be a reasonable conclusion—namely, that it is not safe to dispense with the use of cisterns for ordinary purposes, but that water for drinking should be obtained direct from the main or service pipe. A combination of storage for use in flushing water-closets, etc., and for the supply of water to kitchen boilers, or for the maintenance of a hot water circulating system, etc., together with such a cistern as Dr. Talbot's for the supply of drinking water would, in effect, provide what the health officers desiderate. Dr. Talbot proposes to supply the waste preventers to water-closets direct from the main. But this plan, as I pointed out, and as Dr. Talbot himself allowed, is open to objection, seeing that the house would at once be deprived of water for sanitary purposes whenever the supply, from whatever cause, should be discontinued, whilst the reserve in his cistern would probably be insufficient to provide for the needs of the

household, even allowing that people would take the trouble to flush closets, etc., by hand during the intermission of supply. I really fail to see what other conclusion was open to us than that set out in the resolution which has failed to secure your approval.—I am, etc.,

Kensington, Oct. 19th.

ALBERT T. ORME DUFFIELD.

FEAR IN ANÆSTHESIA BY CHLOROFORM.

SIR,—During my recent holiday in England I attended several of the London hospitals and observed closely the mode of administering chloroform and the results in these institutions. It was over twelve years since I had last witnessed chloroformisation in England, and I had practically forgotten what the process there looked like. What struck me chiefly was the look of terror on the faces of most of the patients as they prepared themselves to submit to the anæsthetic—thus the stertor, the struggling, and the shallow breathing, during which I was frequently in terror lest I should indeed witness a death from chloroform. Nothing could form a greater contrast with all this than the happy anticipation of freedom from pain which, I may say, invariably characterises our patients in the East when chloroform is about to be administered for any purpose. When unconsciousness is setting in frequently a certain amount of struggling takes place, but it is hardly ever violent except in the case of the few who, unhappily, have been the victims of drink.

During the ten years I have been attached to the General Hospital, Madras, in which chloroform has been administered about 2,000 times a year, the above has been my invariable experience. During that period not a single death from chloroform occurred. I am aware that Surgeon-Lieutenant-Colonel Lawrie made a statement to the contrary at the Royal Medical and Chirurgical Society last year, but his statement was incorrect, as I informed you immediately after it was made, and he took no trouble to substantiate it. It was, however, absolutely not the fact. Two deaths occurred during the ten years while the patients were under chloroform—one from hemorrhage and one from suffocation by stercoraceous vomit.

If Dr. Lauder Brunton would turn his attention to this immunity from danger which accompanies the use of chloroform in India some clue might be obtained towards solving its dangerousness in England. It is a point well worth the exercise of the great abilities of that distinguished therapist.—I am, etc.,

JOHN SMYTH, M.D.,

Surgeon-Major I.M.S., Officiating Senior Surgeon, General Hospital, Madras.

September 5th.

THE NOMENCLATURE OF THE BRITISH PHARMACOPOEIA.

SIR,—In the numerous papers which have recently appeared in the *BRITISH MEDICAL JOURNAL*, proposing certain alterations to be made in the forthcoming new edition of the *British Pharmacopœia*, I have not found any remarks on the subject of nomenclature, which appears to me well worth considering and discussing at this time.

I have met with numerous instances in the course of my professional life where I wished that it had been possible for me to prescribe certain drugs without letting the patient know what he was taking. Not a few patients are in the habit of reading the prescriptions which are given them, and become alarmed when they see such drugs as nuxvomica, strychnine, arsenic, potassium bromide, chloroform water, or hydrate of chloral prescribed. They are often under the impression, which is mostly utterly baseless, that certain drugs do not agree with them, and this leads to long and tedious discussions after the consultation is practically finished.

In the old *London Pharmacopœia* a step in the right direction was taken by introducing the "pilula saponis composita" as a preparation of opium, which could thus be prescribed without the patient being aware that he was taking it. A similar useful innovation has been made in the last edition of the *British Pharmacopœia* by terming antipyrin "phenazone."

"Fowler's solution" is as well known to the public as "liquor arsenicalis," but why should we not have such a synonym rendered official as "liquor asiaticus" or perhaps "Hevoztii," after the German physician of the 17th century

who first used arsenic for ague and its sequels long before Fowler, Pearson, and Heim did so. Tinctura nucis vomice might have the synonym "tinctura amara" attached to it. Potassium bromide might be allowed to be prescribed as "sal alterans;" liquor strychnin as "liquor Pelletieri," after the French chemist who discovered the alkaloid in 1818, or as "liquor Ignatii" for obvious reasons. Syrupus hydratis chlorini might receive the synonym of "syrupus Liebreich," and for liquor morphine we might be at liberty to use such as equivalent as "liquor Sernuteri," after the German apothecary who in 1805 discovered that alkaloid; while "aqua formyl" might occasionally stand for aqua chloroformi. By adopting such or similar terms as official synonyms, many patients might be made happier, and a good deal of trouble saved to prescribers.—I am, etc.,

Harley Street, Oct. 8th.

JULIUS ALTHAUS, M.D.

PROFESSIONAL ADVERTISING.

SIR,—Will you allow a provincial medical man, who was formerly a hospital physician, to say that he has read with much interest the letters appearing in the BRITISH MEDICAL JOURNAL on professional advertising, especially those of "Accipe" and "One Who does not Ride a Hobby?" Clergymen of all denominations advertise their sermons, and where they will preach in the daily papers; also, if well-known, their sermons are reported in the newspapers. Lawyers and solicitors have their speeches given for the edification of the public, members of the musical profession advertise their terms, and also have notices—good, bad, and indifferent—of their performances in the public press, but the medical profession must not even be named unless one happens to be on the "top rung of the ladder," and attending some well-known celebrity, or giving a lecture for some charitable object. If things go on as they are it will be looked on as unprofessional to have your name on a brass plate or hall door. Now as a result of this, as well as being overstocked, younger members of the profession take to advertising so-called dispensaries, also as authors of books and pamphlets, whether right or wrong, and, as one who has nothing to gain, I think there should be more latitude allowed for the general practitioner, for really, after all, medical practice in open surgeries is a "business" more than a profession.—I am, etc.,

October 9th.

ANGLO-CYLT.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND ADVERTISING.

SIR,—I am directed by the President and Council of the Royal College of Surgeons in Ireland to forward to you the annexed paragraph, with the request that you will give it the same prominence in the BRITISH MEDICAL JOURNAL as that of the leaderette to which it refers.—I am, etc.,

ROBERT H. WOODS, L.R.C.S.,

Dublin, Oct. 17th.

Sec. of Council.

UNPROFESSIONAL ADVERTISING IN HIGH PLACES.

In reference to the paragraph which appeared in the BRITISH MEDICAL JOURNAL on September 14th, 1895, under the heading of "Unprofessional Advertising in High Places," the Council of the Royal College of Surgeons in Ireland desire that it should be known that their attention was called to the publication referred to, and an ample apology having been received from the writer of the article in the *Irish Field*, it was resolved that his apology be accepted.

CERTIFICATED MIDWIVES AND BOARDS OF GUARDIANS.

SIR,—Dr. Reginald Pratt's letter comes opportunely. The Local Government Board has, I venture to believe, recognised the correctness of the position which the vast majority of practitioners have assumed towards the midwife question, and has acted accordingly.

In our profession organised bodies, in the shape of corporations and associations doubtless exist, but it is not owing to any activity on their part that the Local Government Board has been induced to move. Public opinion has been formed on the question by individuals. Is not this a blot upon our present system of government? We subscribe to associations, and corporations obtain our fees: have we not a right to expect something tangible in return? Dr. Pratt's letter, I think, shows the value of public expression of definite opinion, as I have no doubt that the policy of the hour is in the first place to insist on a fair share of representation on

the General Medical Council; and, in the second, to take steps to force the Council of the British Medical Association to take active steps to carry out the intention of the resolution proposed by Dr. Welsford at the last annual meeting. The corporations being past redemption can be neglected.—I am, etc.,

Haileford, Oct. 22nd.

LOVELL DRAGE.

"CONSUMPTIVE BOWELS" IN YOUNG LIFE.

SIR,—I have read Dr. Walter Carr's paper on this subject in the BRITISH MEDICAL JOURNAL for September 21st (p. 717) with much interest. I have given elsewhere¹ my reasons for thinking that food has less to do with tuberculous infection than is generally supposed. Out of 70 children under 5 years old who died with more or less generalised tuberculosis at Guy's Hospital in ten years, in only 28 could the intestines or their glands have by any possibility been the primary seats, and in many of these other parts appeared jointly responsible for systemic infection. These 28 cases constituted barely 11.4 per cent. of the total cases of systemic infection of all ages during the same period, and of course a very much smaller percentage of the total cases of tuberculous disease. I should say about 5 per cent. of all medical cases were under 5 years of age at Guy's.

On further analysing my notes, however, I find that of 21 children under 2 years of age, 9 showed tubercle in the intestine or mesenteric glands which could not have come to them by way of the lungs, for in no case were any tuberculous masses breaking down. Yet in only 1 of the 21 cases were the lesions such as were at all likely to have given recognisable symptoms during life. In 12 cases the primary seats were elsewhere.

The age period of 10 to 20 appears to furnish a larger proportion of abdominal to other tuberculosis than any other, for of 35 cases 16 came under that category. Out of a total of 246 of all ages, 70, or 28.4 per cent., were possibly abdominal in their origin.

While no one can deny the great relative preponderance of abdominal tuberculous affection under 5 years of age, I for one do not admit that great preponderance which is assumed. Still less do I admit that this is a matter of feeding. For (1) the children of the people who seek hospital accommodation get very little milk, and (2) dirt swallowing is a potent factor which must not be overlooked. All little children swallow much dirt, especially the poor. From the mouth, nose, and upper pharynx tuberculous organisms may find their way to cervical glands, as, it is true, may be also the case with food-remains in the mouth, or be carried down to the stomach when its secretion is alkaline, and thence travel safely to the intestines and glands.

I think we must look to a greater vulnerability in the infantile alimentary tract for its greater proneness to tubercle and not to food.—I am, etc.,

Croydon, Oct. 7th.

J. M. HOSKIN, M.D.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

SIR,—In the BRITISH MEDICAL JOURNAL of September 28th, p. 808, I supplied a table showing the requirements of the medical examining bodies in practical midwifery, with the view of pointing out that these requirements are very inadequate.

In the JOURNAL of October 5th, p. 868, Dr. Archer, while stating to your 19,000 readers that it is not his habit to read my "lengthy effusions," calls attention to my "misleading" figures relating to Dublin University. In my letter there is a printer's error, an "0" having been printed instead of a "6." That this is none other than a printer's error will be proved by referring to a similar table in the *Medical Press* of November 5th, 1890, and also to p. 137 of the *Blue Book on Midwives Registration*, June, 1892.

The next point your correspondent wishes to show where I am in error is when I said that students presenting themselves for their final medical at Dublin University had not to present certificates showing that they had attended a stated number of lying-in cases. I maintain the accuracy of this statement. When working up this table in 1890 to pre-

¹ *Pract. Med.*, January 7th, 1895.

sent to the Select Committee on Midwives Registration, I sent a circular type-written letter to twenty-one medical authorities. The reply from Dublin University was that no stated number of lying-in cases was required. In order to verify the accuracy of this statement I have to-day referred to the Calendar of the University of Dublin, 1890. On page 208 the following regulation appears: "He must also have lodged with the Registrar of the School of Physic his certificate of attendance on practical midwifery." This regulation therefore makes no reference to any number of cases of labour. That of 1895 does.

Your correspondent mistakes the dates, and in his anxiety to show that my figures are "misleading" he makes a quotation from the Dublin Calendar, 1895, p. 186. In doing so, however, he only gives strength to our contention that since 1890, when I began to show that the training of the student in practical midwifery was very insufficient, the medical authorities have tried, in some little way, to improve matters. In proof of this I may refer to the 30 cases now required by Dublin University; to the 20 cases now required by Oxford University, where previously neither attendance upon lectures in midwifery nor clinical instruction were required; and to the statement of the Dean of the Medical School, Liverpool, where he says that the training of students in this branch is under consideration. I fear, however, that although 30 cases of labour must be "attended" by students when presenting themselves for final examination, this "attendance" is often of a visionary description. I would like to see it provided that the student must himself "personally conduct" not less than 30 labours; and under "the direct supervision of a medical practitioner;" and that the names of the women, with the place and date on which the confinements were attended, be noted on the student's certificate. At present a large number of students attend confinements, either by themselves or under the training of a midwife. Fancy a student receiving his clinical medical or surgical training from a medical herbalist or bonesetter! Yet the two cases are parallel.—I am, etc.,

Liverpool, Oct. 14th.

ROBERT R. RENTON.

. The table was printed correctly from Dr. Renton's manuscript.

INADEQUATE SALARIES OF PUBLIC HEALTH APPOINTMENTS.

SIR,—Would you allow me to say a few words in support of the letter in your issue of October 19th, signed "Public Health." I should, however, prefer to discuss the matter not from the officials'—or, as some would perhaps say, the pecuniary—point of view, but from the broader aspect of the public good.

Your correspondent refers to a case in which £100 a year is the remuneration proposed to be paid for the services of a county medical officer of health. County councils are very much given to follow one another's example, and I believe I am stating an open secret when I say that this amount of salary was adopted from the example of another county which was one of the latest to appoint a county medical officer of health. In this case the county council was able to secure the services of a retired medical officer of health of some eminence and blessed with ample private means for £100 a year.

Now, is it for the advantage of the country that the post of medical officer of health for a county council should be regarded as almost honorary in character, and rewarded with a corresponding salary?

Owing to the working of the Excepted Borough Clauses of the 1888 Act, the districts over which county councils have sanitary jurisdiction are almost entirely made up of comparatively small towns and purely rural districts, and anyone that is well acquainted with the sanitary progress of the last twenty years knows well that it is precisely in these districts that little (if any) sanitary progress has been made, and that so much remains to be done. This will probably be admitted, but the question will naturally follow, What are the local district medical officers of health doing? I am a local medical officer of health, and in reply I have to state that they are doing, and have done, their duty in annually and periodically reporting the condition of their districts to the local authorities by whom they are appointed. No medical

officer of health worth his salt would do otherwise, even although he may be, as most are, subject to periodic re-election. Having done this much, he has no power to do more, even if inclined to be Quixotic enough to try to force schemes of sanitary improvement down the throats of his sanitary board before whom his re-election (or the reverse) comes on, as in my own case, in the course of few months.

That there is abundance of work for county medical officers of health, and that they are welcomed by the district medical officers of health, has been amply proved in the case of those counties where such officers have been appointed at a living wage.—I am, etc.

October 21st.

A DISTRICT M.O.H.

CYCLING FOR MEDICAL MEN.

SIR,—The editorial note upon this subject which appeared in the *British Medical Journal* for August 24th, and in which my opinion was given, has brought to me many inquiries regarding cycling, and my observations have been criticised in the lay press (the *Manchester Guardian*) by a correspondent who professes to be an expert. He writes in support of the tricycle, stating that it is not so much inferior to the bicycle as I have stated, and he remarks that with old people especially the tricycle is best. He refers to those who have lost their power of balance, or who are incapacitated by some physical weakness.

In giving the opinion above referred to, I confined myself to answering the questions of the correspondent "An Old Member," and therefore I was not advocating cycling for incapable or cripples, but for active medical men, and I maintain that for that purpose there is no comparison between the bicycle and the tricycle. If the journeys to be made are simply round about a small town, some men might, perhaps, prefer a tricycle, but for any lengthened distance there can be no question that the bicycle has an enormous advantage. When we are dealing with patients, and especially with cripples of various kinds the case is quite different, and as a rule a tricycle is necessary. For instance, we may have an individual paralysed in both legs, when it is obvious that if he cycles he must ride a tricycle worked with the arms; or one leg only may be deficient, or various other complications may exist which must be dealt with according to their individual peculiarities.

The chief point to be noted is that in riding a tricycle any extra effort, either in putting on pace, or riding against wind, or on a heavy road, causes a strain upon the heart which with the bicycle I have not experienced. With the latter we may get tired, or even in time exhausted, but without that embarrassment of the circulation which can be so easily produced with the heavier and more laborious machine.

In the case of heavy men the chief difficulty is the seat. I have tried a great variety, and find the pneumatic seats very comfortable to sit upon, but not quite so agreeable when working the machine.

After repeated trials, I have selected a hard smooth leather seat with a short peak, which with some further modifications will, I think, be perfectly satisfactory. I shall be happy to communicate the full particulars of this seat when I have completed my experiments.—I am, etc.,

Queen Anne Street, W., Oct. 14th.

NORRIS SMITH,

Surgeon to the City Orthopaedic Hospital.

THE MADAGASCAR JIGGER.

SIR,—Your interesting note on *pulex penetrans* reminds me of an unusual experience I met with in Eastern Equatorial Africa in 1875.

Whilst sauntering in the early morn along a native track about eighteen miles inland, my attention was attracted by a curious agitation across the pathway, as if a stream of living dust was being driven out of the dry and dusty jungle. A nearer approach and examination proved the phenomenon to be a migratory movement of fleas. The column of these *aphaniptera* was about two feet in breadth, and consisted of an innumerable host rapidly traversing both the ground and air by characteristic leaps and bounds. I watched the onward and regular procession of this mighty swarm for a quarter of an hour, and left the formidable multitude undiminished in numbers, and apparently under orders for a neighbouring village.

Herr Hildebrandt, travelling for the Berlin Naturalist Society, was at that time amongst us. He had neither seen nor heard of such an uncommon enterprise amongst fleas, and considered this to be an almost unique experience. At that time East Africa was not a chigoe-infected district, but if it travels after the manner of the above it is no marvel that the continent should be overspread in the course of a few years.—I am, etc.,

Darlington, Oct. 7th.

EDWD. W. FORSTER.

VOLUNTEER MEDICAL SERVICE.

SIR.—As it is probable that a Commission may be appointed to consider the various questions which are raised by the commanding officers of the volunteer force, and as such officers are about to meet to ventilate the various matters requiring consideration at the War Office, I would suggest that one question should be the desirability of asking for a small annual grant for the stretcher section of each regiment. Such a grant has been conceded to the signallers, and a small annual sum on the same or similar lines granted for ambulance work would interest the stretcher bearers and encourage them to keep up their efficiency year by year. Ambulance work is most important in time of war, and in camp and other manoeuvres is of much practical utility, knowing, as one does, that lives may easily ebb and pass away when a little skilled knowledge of the simplest kind would avoid many such catastrophes. To acquire even that simple knowledge regimental stretcher bearers give up much time in attending the classes of instruction and the necessary drills in addition to their many regimental requirements. The grant need only be small (say 7s. per efficient bearer), but to be earned the work must be a reality, and complete efficiency insisted on each year. At each inspection at the present time the section has to be present, and its efficiency has to be tested by the inspecting officer, who reports officially on its condition. Surely if its existence and efficiency be thus recognised, a small grant might be conceded which should be expended in providing all ambulance requisites and appliances such as may be necessary for the proper and satisfactory teaching of the various classes. These stores should be reported on each year by the senior medical officer, who would be responsible for them.

I cannot but think that this suggestion will commend itself to all commanding officers who have the welfare of their men at heart, and who may only require the matter to be brought under their notice by their regimental medical officers, who are now asked to endorse and urge the adoption of this suggestion which I have thus ventured to propose.—I am, etc.,

M. BAINES, V.D.,

Surgeon-Lieutenant Colonel.

Headquarters, 1st Middlesex V.R.E., College Street, S.W., Oct. 8th.

THE RARITY OF SUDDEN DEATH IN CHILDREN.

SIR.—In the *BRITISH MEDICAL JOURNAL* of October 12th you call attention, in reviewing Dr. Luff's *Forensic Medicine and Toxicology*, to the rarity of the occurrence of sudden death in children; but surely the cases have not been, as you suggest, so few as to render any reference to the subject superfluous in a work on forensic medicine. I am reminded of a case which occurred under somewhat peculiar circumstances in the out-patient department of St. Thomas's Hospital in May, 1883. The child, a healthy-looking infant of 3 months, died in its mother's arms whilst preparations for an operation upon it (circumcision) were being made. The child appeared to die quite suddenly, without convulsion, cry, or other warning. It was at once taken in hand, but there was never any attempt at respiration, and no heart sounds could be detected. Inversion and artificial respiration met with no response; a finger passed into the throat detected nothing of the nature of food or foreign body, nor was any reflex excited by this procedure. No food had been given to the child, and there was no suspicion of foul play. It is perhaps a pity that there was no post-mortem examination in this case.

A point of interest is that had the event occurred ten minutes later it would have added another to the list of "deaths under chloroform." At the same time one cannot help reflecting whether it is not just possible that had the

child been at the time under anesthesia the fatality might, owing to the altered circumstances, never have occurred.—I am, etc.,

Upper Tooting, Oct. 19th.

EDWIN SMITH, M.B.Lond.

LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS AND THE TITLE OF "PHYSICIAN."

SIR.—I think many licentiates of the London College will thank "F.R.C.P." for his letter in the *BRITISH MEDICAL JOURNAL* of October 19th. As we licentiates hold our diploma only during "good behaviour," and taking into consideration the great distinction and prestige of the College itself, I should imagine that we have as much right to the title of "Physician" as an M.D. of any university in the United Kingdom. I believe that a large majority of us "live up" to the traditions of the College and obey its by-laws both in letter and spirit, although comparatively few of us have the chance of becoming Members or Fellows.—I am, etc.,

October 20th.

L.R.C.P.Lond.

OBITUARY.

SURGEON-GENERAL G. A. F. SHELTON, M.B.

WE have to chronicle the death of yet another retired surgeon-general—the fifth within a month—a mortality altogether unprecedented in a necessarily limited class in so short a time.

Surgeon-General Shelton died on the same day as Sir Thomas Crawford—October 12th—in Bolton Street, Piccadilly, in his 74th year. About a year ago he had a slight stroke of paralysis, from which he never fully recovered, and succumbed to a second attack after a short illness. Born in 1821, he was the second son of Captain Shelton, of Rossmore, co. Limerick—a gallant officer, who, as captain of the 53rd Regiment, lost an arm at Waterloo. He was educated and graduated at Trinity College, Dublin, and entered the Army Medical Service in 1845, and served for a number of years in the 48th Regiment, including the Crimea. He gradually rose to be Surgeon-General, and his last years in that rank were spent at headquarters, where his great urbanity made him many friends. He retired in 1882.

The older generation of army medical and many other officers will long remember Shelton in his prime—the fine, handsome, courteous, and witty Irishman—the best of companions and warmest of friends.

DR. FREDERICK BERNARD BETTS, M.R.C.S., L.R.C.P., died on September 4th, at Antofagasta, Chili, after an illness of eight days, due to septic pneumonia. Dr. Betts, who was in his 29th year, received his medical education at the Westminster Hospital, where he entered in 1884. He obtained the diplomas of the Conjoint Board in 1889, after a student career remarkable for industry and ability. Subsequently he held all the resident posts at the Westminster Hospital. Failing health induced him to take the appointment of Surgeon in the R.M.S. *Iberia*, in which he made three voyages to South America. He then served as Resident Medical Officer to Queen Charlotte's Lying-in Hospital. On relinquishing this office he was appointed Surgeon to the Huanchaca Silver Mine and Railway at Antofagasta, where he went in 1893. Shortly after his arrival in South America he obtained the degree of M.D. from the University of Santiago. At Antofagasta he had already earned the esteem of those with whom he came in contact, and his funeral was attended by over 2,000 persons, including the foreign Consuls. The *Chilian Times*, in an obituary notice, said of him: "Young, gifted, terribly in earnest, and thoroughly devoted to his profession, he was only happy when busy relieving the pains and sufferings of his fellow men." In this country his death is keenly felt by those who knew him, as well as by his relatives.

WE regret to report the death, by suicide, of Surgeon-Major NASH, of Herbert Road, Dublin. He had been suffering from sleeplessness, and on October 21st he rose early, wrote a letter, and then shot himself through the heart with

a revolver. The deceased had served in the 27th Enniskillens, and was in his 67th year. Since his retirement from the service, he had taken a prominent part in municipal matters, and he was very much respected and beloved.

We have to record the death of Dr. THOMAS GROOM, of Whitechurch, who is said to have been the oldest medical practitioner in Shropshire. He died on October 7th, and had he lived a fortnight longer would have attained the age of 86. He was the fourth son of the late Mr. John Groom, of Hardwick Grange, but was born at Waverly Hall, Shropshire. He was apprenticed to the late Dr. Gwynne, of Wem, and studied subsequently at Guy's and St. Thomas's Hospitals. Having obtained the diplomas of L.S.A. (1833) and M.R.C.S. (1834), he commenced practice in Whitechurch, and for many years held a leading position in that town and neighbourhood. He was an ardent sportsman as well as a successful practitioner, and enjoyed a wide popularity. In 1861 he was elected a Fellow of the Royal College of Surgeons. For some years he had retired from the more active duties of his profession, but he had so endeared himself to a large circle of friends by his cheerful and genial disposition that his funeral called forth many tokens of the esteem and regard in which he was held. He was twice married, but leaves no family.

The death is announced of Mr. JOHNSON MARTIN, of Great Lever, near Bolton, who was one of the oldest and best known residents in the district. He was born in 1821, and was the son of Dr. Robert Martin. He was educated at the Pine Street School of Medicine, Manchester, now merged in Owens College, and was apprenticed to his brother, Thomas Martin, of Little Hulton. Mr. Martin took the diploma of L.S.A. in 1851, and afterwards studied at King's College Hospital, finally taking the diploma of L.F.P.S. and L.M. of Glasgow in 1857. For many years he filled the post of medical officer and public vaccinator for the Lever District of the Bolton Union, and for a period of five years was medical officer of health to the rural sanitary authority, being very active in his efforts to promote sanitation.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are Dr. Joseph Ottinger, Emeritus Professor of the History of Medicine in the University of Cracow, one of the founders of the *Przeglad Lekarski*, and author of numerous writings on medico-historical, hygienic, and political subjects, aged 77; and Dr. A. Gresson, Physician to the Hôpital des Anglais, Liège, and formerly Lecturer on Anatomy in the University of that city.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 3s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A SURGEON-CAPTAIN, who has been home a year, will exchange after January next for a whole or part tour abroad. India (Punjab or Bengal) preferred. Apply to Hakim, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

THE NAVY.

THE following appointments have been made at the Admiralty: JOHN L. BARRINGTON, Staff-Surgeon, to the *Africa*, November 5th; HENRY S. JACKSON, Staff-Surgeon, to the *Porte*, November 5th; FREDERICK W. STEBBICKS, Surgeon, to the *Infatigable*, November 5th; GORDON G. W. HENRY to be Surgeon and Agent at Portlock and Mizenhead, October 18th; W. J. CAMMICHAN to be Surgeon and Agent at Collieston, October 19th.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL JOSEPH W. O'M. MARTIN, M.B., died at Dublin on September 16th. He was appointed Assistant Surgeon, April 1st, 1871; Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1883; and Surgeon-Lieutenant Colonel, April 1st, 1891; quitting the service on retired pay, September 9th, 1891. He was in the Zulu war in 1879 (medal with clasp), and in the Boer war of 1880-81, when he was in medical charge of the garrison of Wakkersdroom during the defence of that town. He also served in the Sudan campaign in 1885, receiving the medal with clasp and the Khedive's bronze star.

Officers of the Army Medical Staff with less than seven years' service may in future be allowed to exchange with officers of the Indian Medical Service.

CHANGES OF STATION.

THE following changes of Station amongst the officers of the Army Medical Staff have been officially notified to have taken place during the past month:

	From	To
Surgeon-Colonel H. S. Muir, M.D.	Chester	Secunderabad.
Brig.-Surgeon-Lt.-Col. G. F. Pollock, M.B.	Punjab	Bengal.
W. H. M. Namara, M.D.	Almashot	Egypt.
J. G. Williamson	Liver	Jamaica.
R. Harman, M.B.	Devonport	Liver.
Surgeon-Lieut.-Col. D. B. Brown	Pierhead	Punjab.
Surgeon-Major H. C. Kirkpatrick, M.D.	Gosport	Winchester.
E. R. Power, M.B.	Devonport	Plymouth.
M. L. Lane, M.B.	Portsmouth	Bombay.
A. Peterkin, M.B.	Shorncliffe	Madras.
J. H. A. Rhodes	Carragh	Punjab.
G. J. Coates, M.D.	Cork	Bengal.
M. W. O'Keefe, M.D.	Belfast	Punjab.
G. E. Weston	Gosport	Bombay.
J. O. Haslett, M.D.	Devonport	Bengal.
H. S. McGill	Dublin	Galway.
V. E. Hunter	Portsmouth	Gosport.
Surgeon-Capt. R. J. A. Durant	York	Madras.
G. Birt	Punjab	Bengal.
H. J. Fletcher, M.B.	Almashot	Gibraltar.
F. A. Saw, M.B.	Chester	Birmingham.
A. Kennedy	Dublin	Malta.
T. Browning	Limerick	Flipperry.
G. F. H. Marks, M.D.	Shorncliffe	Lydd.
H. Holyoake	Tower	Warley.
Surgeon-Lieut. F. R. Buswell	Carragh	Madras.
F. A. Symons, M.B.	Ferriway	—
J. B. Anderson	Chatham	Bombay.
P. Evans	Portsmouth	Gosport.
A. E. Milner	Gosport	Portsmouth.
H. W. Vaughan-Williams, M.B.	Cork	Ferriway.
D. Lawson	Portsmouth	Gosport.
L. F. Smith, M.B.	—	Aldershot.
R. J. Blackham	—	—
R. H. Fairlie, M.B.	—	—
G. T. K. Maurice	—	Portsmouth.
R. Fawcett	—	—
J. V. Forrest, M.B.	—	Dublin.
H. W. Gratton	—	Dover.
F. E. Gunter	—	Dublin.
J. H. Campbell	—	—
J. Grech	—	—
Quartermaster E. Thowless	Natal	Cape Town.
W. J. Blackman	Cape of Good Hope	Natal.

Surgeon-Lieutenant-Colonel O. F. Mellor, Retired List, has vacated his position in medical charge at Galway.

INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON-LIEUTENANT-COLONEL S. O'B. BANKS, Bombay Establishment, is promoted to be Surgeon-Colonel from September 18th. He joined the service as Assistant-Surgeon, October 1st, 1863, and was appointed Brigade-Surgeon-Lieutenant-Colonel, November 10th, 1888. He was in the Abyssinian war in 1867-68, and was at the capture of Magdala (medal).

Deputy-Surgeon-General ROBERT WILLIAM COCKERILL, late of the Madras Establishment, died on October 5th. He joined the Ordnance Medical Department in 1854, and first saw service in the Crimean war. He was present at the battle of Inkerman, and was wounded in the advanced trenches before Sebastopol. He received the Crimean medal with two clasps, and the Turkish medal. In 1856 he joined the Indian Medical Department, and, proceeding in medical charge of the Madras troops, served through the China campaign of 1857-58, being present at the capture and destruction of Nantaw, and receiving the China medal. In 1860 he was appointed to the Madras General Hospital and Medical College, where he held various professorships till his retirement in 1886.

The following promotions of Surgeon-Lieutenants to be Surgeon-Captains from July 27th, and which have been already announced in the BRITISH MEDICAL JOURNAL, have received the approval of the Queen:—Bengal—P. B. HAIG, T. W. A. FULLERTON, R. H. MALCOLM, E. V. HUGO, M.D.; H. G. MELVILLE, A. O. HUBBARD, C. G. R. SCOTT, H. A. SMITH, D. R. GREEN, G. M. C. SMITH, H. M. EARLE, J. G. HULBERT, M.D., P. C. GABRIEL, J. L. MACRAE, Bombay—F. E. SWINTON, S. H. BURNETT, THOMAS JACKSON.

Brigade-Surgeon-Lieutenant Colonel ANDREW BARRY, M.D., Bombay Establishment, has retired from the service, which he entered as Assistant-Surgeon, March 31st, 1855. He served in the expedition against the Wagheers in 1850-51, including the operations of the Kattywar Field Force in the Borda Hills; in the Abyssinian campaign in 1867-68 (medal), and in the Afghan war in 1879-80, when he took part in the march to Candahar with the force under Major-General Phayre (medal).

Surgeon-Colonel S. O'B. BANKS, Bombay Establishment, is appointed Principal Medical Officer, Nagpore District, vice Surgeon-Colonel H. Cook, M.D., whose tenure of service expired on September 18th.

Surgeon Captain F. E. SWINTON, Bombay Establishment, has been appointed personal assistant to the Principal Medical Officer, Bombay Command, from October 26th, on which date Brigade-Surgeon-Lieutenant-Colonel G. W. R. Robertson, M.D., completes his tenure of service.

The Secretary of State for India has approved of the orders issued by the Government of India in regard to the continuance of the local allowance admissible to surgeon-captains and surgeon-lieutenants on duty in the Naga, North Lushai, and Chin Hills and Manipure, for a period not exceeding three months, while they are attending a course of military instruction in or out of those localities.

Sanction has been accorded to the withdrawal from the Tochi Valley of the Field Hospital Corps as soon as the regimental hospital can be formed. As regards the medical arrangements for Wano, that post is

to be formed into a permanent contingent with a reduced garrison, so that the Field Hospital service is no longer required, and regimental hospitals will be established as soon as practicable. Orders for demobilising No. 14 and Field Hospital Corps will therefore issue in due course.

THE VOLUNTEERS

SURGEON-MAJOR T. R. PRANSON, M.D., 1st North Riding of Yorkshire Artillery (Western Division Royal Artillery), is promoted to be Surgeon-Lieutenant-Colonel, October 16th.

Captain J. F. BLAKE CAMPBELL is appointed Surgeon-Lieutenant in the 1st Cheshire Engineers, Fortress and Railway Forces Royal Engineers, October 16th.

Surgeon-Captain J. DENHOLM, M.B., 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers, has resigned his commission, with permission to retain his rank and uniform, October 16th.

DEARTH OF CANDIDATES FOR THE A.M.S.

THE cause of the unpopularity of the A.M.S. as a career is clearly pointed out in a letter to the *Army and Navy Gazette* of October 6th, and there are few who will not agree with the reasons therein set forth. One important point, though, is omitted in that letter, namely, the difficulties medical officers encounter in obtaining leave, pointed out by a correspondent in our columns on October 12th. These difficulties are always experienced during the relief season. The fact must be reasserted that the strength of the A.M.S. is barely sufficient for the duties it is called on to perform, and no margin exists for contingencies. This statement is applicable not only to Great Britain but to India, from whence complaints are constantly received. Economy is the order of the day, and if it is to be carried out it must be at the expense of the Army Medical Staff.

APPOINTMENTS IN THE ARMY MEDICAL SERVICE.

THE *Armed Forces* of October 15th notices the following changes in the administrative rank as about to be carried out: Surgeon-Colonel Maxham, P.M.O. York, to South Africa, in relief of Surgeon-Colonel J. B. Hamilton, P.M.O. Cape Town; Surgeon Colonel T. A. Hughes, P.M.O. Devonport, to Chester, as P.M.O. in succession to Surgeon-Colonel Muir, Gibraltar; to India; Surgeon-Colonel Catherwood, P.M.O. Colchester, to Gibraltar, in relief of Surgeon-Major-General Lower, to be retired by age. This points to Gibraltar becoming a surgeon-colonel's administration, instead of as heretofore, a surgeon-major-general's billet. At the same time, Devonport will become a surgeon-major-general's, in lieu of a surgeon-colonel's administration. Thus the rumoured abolition of one surgeon-major-general would appear to be without foundation.

BARRACKS IN DUBLIN.

A CORRESPONDENT, writing to the *Army and Navy Gazette* in reference to the death of Lieutenant Bethell in Dublin, makes an attack upon the system by which troops are located in what he terms loathsome quarters. Mr. Bethell died of scarlatina; how contracted is not known. But with regard to the barracks we may point out that for any insanitary condition existing in them the military authorities are responsible, and not the corporation. The Medical Department and the Engineers ought, between them, to be able to secure healthy quarters for the troops, and we think that they are primarily responsible if any well grounded complaint can be made.

THE INDIAN MEDICAL SERVICE.

A VERY important letter, bearing on Mr. Ernest Hart's address, appears in the *Times* of October 1st, headed "Promotion in the Indian Medical Service," signed I.M.S. The writer adverts to the present system of promotion being clearly indefensible and insists on the need of a Promotion Board, which would be, he says, more satisfactory to all concerned. He suggests that this Board should be constituted by the Commander-in-Chief as President and the two Surgeon-Major-Generals at Headquarters (Simla) as members; thus bringing the matter of promotions for the I.M.S. into accord with that now existing for the A.M.S.

THE ARMY HOSPITAL NATIVE CORPS.

OWING to the transfer of the Quetta District from the Bengal Presidency to the Bombay Command it has been found necessary to revise the Army Hospital Native Corps. The Bengal A.H.N.C. has accordingly been reduced to the extent of the authorized establishments for the Quetta District, and the Bombay Command A.H.N.C. has been increased by as much.

THE CHITRAL DESPATCHES.

DESPATCHES respecting the operations of the Chitral Relief Force under Sir Robert Low have been published. In relating the operations Sir George White, the Commander in Chief in India, speaks as follows: "To the careful medical arrangements and to increased sanitary precautions may be ascribed, in Sir George White's opinion, the comparative immunity from disease and the general good health that the troops have enjoyed under very trying conditions. These results could not have been attained without the great foresight and administrative experience of the late principal medical officer, Sir Her Majesty's Forces in India, Surgeon-Major-General B. A. Shaw, F.R.S., and of the officer now filling that appointment, Surgeon-Major-General A. A. Gore, and their efforts have been well seconded by Surgeon-Major T. M. Macdonell, principal medical officer with the force, and the medical officers under his orders." Sir Robert Low, in bringing to notice those officers who had especially distinguished themselves, mentions Surgeon-Lieutenant D. W. Sutherland, Bengal Establishment, for the promptitude and courage he displayed in attending on the wounded under a short range fire. Regarding the principal medical officers he says: "Surgeon-Colonel T. Macdonell, Army Medical Staff, principal medical officer with the force, is an officer of ability and experience, and his management of the medical and sanitary arrangements connected with the force have been most successful. Sur-

geon-Colonel G. Thompson, M.B., Indian Medical Service, Principal Medical Officer (Bde of Communications), an officer of judgment and experience, administered his department in a very satisfactory manner."

Other medical officers especially brought to notice for their services are: Surgeon-Lieutenant-Colonel W. Donovan, Army Medical Staff; Surgeon-Lieutenant-Colonel F. F. O'Connor, Bengal Establishment; Surgeon-Lieutenant-Colonel W. A. Stammers, Bengal Establishment; and Surgeon-Major G. Coultis, M.B., Army Medical Staff.

ARMY MEDICAL OFFICERS AND SANITARY REFORM.

A CORRESPONDENT sends us a long communication on this subject of which the following is a summary. Medical officers have almost insuperable difficulty in getting sanitary recommendations carried out for several reasons. They can only recommend, it is for the commanding officer to take executive action; if he declines or neglects to do so, there are no means of bringing him to book; and even if disease or death results from his inaction, there is no punishment as in the French Army. According to Section 21, par. 13A, Queen's Regulations, all sanitary questions in a district submitted to the general officer commanding should be referred to the principal medical officer, who submits them to him, and if so desired, deals with them "by order" of the general the same as officers on his "staff" deal with military matters "by order." But in the said regulation acted on? Some member of the House of Commons might find out when and where. The apathy of the generals and the jealousy of the staff regarding "by order" powers have stood in its way. There can be no doubt such regulations would be less likely to be dead letters if the Director-General formed part of the proposed new War Office Boards and Councils, and had thus direct access to the Secretary of State for War. Sanitary engineering must be made a branch of study of the Royal Engineers, in whose hands sanitary improvements are carried out; there is a sad waste of public money through ignorance or indifference towards this matter. There is the question also whether senior medical officers stand in the way of the views of their juniors, and "water down" the reports of the latter, so as to avoid awkward interpellations in Parliament. Cannot original reports be sometimes published, and not all held to be "confidential" or "privileged"?

"* There may be, and no doubt is, a good deal in what our correspondent alleges, for he is a keen and well-informed critic of our defective military system. But we cannot for a moment believe there is actual indifference among commanding officers, their staff, or Royal Engineers, towards sanitary matters, any more than among principal medical officers. Ordinary incidental defects and repairs are defrayed from the consolidated sum voted annually to the Royal Engineers; larger works by special grants. It is in the latter the pinch comes. There can be no doubt that much money is wasted in attempted remedying of sanitary defects in our hopelessly imperfect old barracks, which it would be cheaper in the end to level at once, and rebuild.

A SELFISH POLICY.

ESPRIT DE CORPS writes: Selfishness is undoubtedly the bane of failure in the Army Medical Service, and yet the policy of every man for himself and the devil take the rest is very shortsighted. Although it brings occasional success it can never result in respect nor in developing the respect of others.

There are at present 500 officers in the Department, yet, with rare exceptions, all are afraid to make the slightest move, official or otherwise, towards progress. The idea is to "sit tight." Let others work, as, for instance, the Editor of the *BRITISH MEDICAL JOURNAL*, and a few officers of note, but we will be "cautious." It is dangerous to agitate, such a policy is best man and common sense. All are ready to confide in half-whispers what they know is respecting the Department, but to have the courage of one's opinions is a different matter. Each one thinks, why should I make myself a martyr? Then, let us ask, whose duty is it to recommend those changes which are so necessary? Clearly it is the seniors. But they will not do it. Here, again, we are brought face to face with that selfishness which is so striking a characteristic of the Army Medical Service as compared with regimental officers.

But mere passive selfishness is not the worst. Combative officers tell us we have no such enemies among them as we have in our own corps. There is a current story that a member of the department, now retired, refused leave to the officers of his division on the ground that he would thus strengthen his claim for an increase in numbers. It is said that at the same time he was actually submitting proposals to the authorities for a diminution in the staff. Going back a quarter of a century, tradition has it that an old army surgeon collected over 50 candidates for the Army Medical Department at a time when the War Office was at its wit's end to get candidates coming in to the new and courageous action. Referring to recent times, we find long articles in the *Lancet* and *Medical Magazine* denouncing the efforts of the Army Medical Staff in India, on the ground that since we were disarmed from regiments we have cramped our sanitary work and hence enter's fever has increased! Yet such attack possesses passing muster as the evidence of intelligent experience. When the history of our corps comes to be written, as it will before long, these efforts will not pass unrecorded.

It is not an easy matter to do a loyal part in the Army Medical Service. The traveller on this honourable path involves himself in difficulties. He does not accept a rub with grateful smile and humble demeanour. He stands up for the honour of his order, work, and refuses to regard himself as a low-class outsider, humiliated by the notice of other army men. He supports his juniors and takes their responsibilities on his shoulders, instead of doing the reverse. And it is an open question whether in the long run he does not succeed as well as the man who plays an underhand game, and gives his department away on every opportunity.

Times are changing. The new Commander in Chief knows better

"POACHING."

A JAX writes: A and B are country practitioners whose districts meet at a certain point. A has fitted up a surgery at a shop in a village in B's district and attends there regularly twice a week to see patients and dispense medicine. What steps can B take to put a stop to this?

*A. We do not think any steps can be taken by B. to prevent A. from continuing the course he has adopted. B. cannot have an exclusive right to practise in any given district.

TOUTING SOCIETIES AND PERSONAL ADVERTISEMENT.

Nemo asks whether there is any objection to supplying labels with his name, address, and hours of consultation to agents of the London and Manchester Assurance Society, provided that they promise not to enrol any members who are the patients of other practitioners, and only put them in the books of members legitimately accepted for himself. There is every objection. The use of labels bearing the practitioner's name and address for any purpose is at the present day more than questionable, and when they are entrusted wholesale to an ordinary commercial agent for distribution with no better guarantee against abuse than an understanding like the above, such a practice must be strongly condemned. As to the absence of "touting" on the part of the agents of the London and Manchester Assurance Society in our correspondent's neighbourhood, and the great discretion they display in only taking "poor" patients, some of his brother practitioners might tell him another tale. It is the object of these agents for their own sake to get as many members as they can, and in doing this it is not to be expected they will be at all scrupulous in observing professional decorum. It moreover, assists them greatly if they can show to members of the public credentials from any well known practitioner in the neighbourhood where they are canvassing, and for this purpose labels would be a veritable godsend.

D. S.—The enclosed prospectus of the London and Manchester Assurance Society, advertising broadcast the names of medical practitioners, many of whom are doubtless men of the greatest respectability, is, unfortunately, only a sample of circulars which are being distributed largely by this Society in nearly every part of the country. We have frequently commented on the professional degradation involved in such forms of advertisement, and have over and over again expressed surprise that the small emolument likely to be gained by such practices should be sufficient to tempt practitioners.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

COUNTY MEDICAL OFFICERS OF HEALTH AND LOCAL APPOINTMENTS.

ACCORDING to the *Liverpool Post* the proposition of the Cheshire County Council that Mr. Vacher, the county medical officer of health, should act as health officer for the districts in the Mid-Cheshire combination, has not met with acceptance on the part of the local authorities concerned. The vacancy arises from the death of Mr. Makinson Fox, who had held the appointment for many years. One of the districts has decided to withdraw, but the rest are apparently disposed to remain in combination for the purpose of appointing a successor to Mr. Fox. The secession of Altrincham is to be regretted, but scarcely so the decision to decline the overtures of the county council. The administrative county of Cheshire is large enough to afford ample scope for the energies of a first rate county medical officer, and Mr. Vacher's ability and experience have long ago placed him in the front rank. The county is wealthy enough to place the appointment on a proper footing without any bargaining with local authorities. In the early days of county sanitary government, when there was no experience to go upon, it seemed probable that advantage would be taken of the permissive clause which sanctions such arrangements. Worcestershire began work in that way, and Essex has just followed suit, but in both instances there was a special reason in the fact that the newly appointed county officer already held office under local authorities in the county; but the few years which have elapsed since 1888 have not been without their lessons. The pioneer counties have demonstrated that a great deal of useful work is possible, even with the apparently shadowy and indefinite powers at first given, and there have been already many additions of no small importance. From the standpoint of both classes of authorities, county and local, the dual tenure is of doubtful convenience. Districts in which the county officer is also health officer under the Public Health Act are not in the same position with regard to the county council as are the other portions of the county, and in the event of the county medical officer having to advise the county council to bring pressure to bear in a district for which he was medical officer of health, his divided allegiance would not improbably prove irksome to himself and unsatisfactory to at least one of the contending parties. The smaller counties, which may with more reason plead inability to support an efficient staff of their own, may perhaps find it expedient to adopt some such course as that which Cheshire contemplated, although a better way would be to combine with a neighbouring county standing in like need; but Cheshire is scarcely a minor county.

SANITARY RELATIONS OF PLUMBERS.

At the opening lecture of the eighth session of the Glasgow Technical College Plumbing Classes on October 12th, Mr. Peter Fyfe, Chief Sanitary Inspector, City of Glasgow, gave a suggestive and stimulating address to the students. In the introduction of his lecture he emphasised the absolute need in the present day of combining the theoretical and the prac-

tical, of uniting sound theory to sensible practice. He said the theoretical faddist and the rule of thumb man were equally unfitted for the problems now confronting us. It was too often taken for granted by young men entering on a trade that all had been discovered that was worth discovering, but to the plumber the door was open to much greater things in the future than had been accomplished in the past. Especially the continual development of great cities called upon the plumber for the highest exercise of his resource. Even the great water carriage sewage system, which had been carried to such perfection, was capable of much improvement. Again, plumbers were becoming more and more concerned in the efficient distribution of hot water. In the cold winter months a free distribution of cheap hot water was really a hygienic consideration. The man would be a public benefactor who discovered a simple and efficient remedy for the hot water starvation prevalent amongst the poorer classes. This would involve a complete grasp of the principles of hot water circulation, pressure reduction, friction in pipes, and heat absorption. In the new field of applied hydrodynamics the plumber might find an important place. In large cities hydraulic power was now being distributed, and recently there had been inaugurated in Glasgow municipal hydraulic works, from which such power would be dispensed through the principal streets at a pressure of eleven hundred pounds to the square inch. With this high pressure small rotative motors would come into the market, such as impulse turbines, to drive light machinery. It would also afford the means of generating the electric current. Mr. Fyfe then discussed the equipment necessary to fit plumbers for the duties of sanitary inspectors, including the power of writing intelligent reports, skill in drawing, and the study of such subjects as ventilation, heating, the elements of chemistry, etc.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,326 births and 2,878 deaths were registered during the week ending Saturday, October 19th. The annual rate of mortality in these towns, which had been 19.4 and 21.0 per 1,000 in the two preceding weeks, declined again to 19.1 last week. Among these large towns the lowest death-rates were 10.4 in Derby, 13.1 in Nottingham, and 13.6 in Croydon; the highest rates were 26.6 in Salford, 26.7 in Burnley, and 31.5 in Blackburn. In the thirty-two provincial towns the mean death-rate was 19.8 per 1,000, and exceeded by 1.9 the rate recorded in London, which was 17.9 per 1,000. The zymotic death-rate in the thirty-three towns averaged 3.3 per 1,000; in London the rate was equal to 2.8, while it averaged 3.6 per 1,000 in the thirty-two provincial towns, and was highest in Salford, Burnley, and Blackburn. Measles caused a death-rate of 3.2 in Swansea and 5 in Blackburn; whooping-cough of 1.1 in Gateshead; "fever" of 1.7 in Bolton and 1.9 in Sunderland; and diarrhoea of 3.5 in Salford, 3.8 in Gateshead, 6.3 in Burnley, and 6.5 in Blackburn. The 107 deaths from diphtheria in the thirty-three towns included 76 in London, 5 in West Ham, and 4 in Manchester. One fatal case of small-pox was registered in London, but not one in any of the thirty-two large provincial towns. There were 119 small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday last, October 19th, against 234, 198, and 118 at the end of the three preceding weeks; 7 new cases were admitted during the week, against 21, 17, and 9 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last was 2,538, against 2,507, 2,502, and 2,827 at the end of the three preceding weeks; 241 new cases were admitted during the week, against 339, 252, and 332 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday last, October 19th, 833 births and 539 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had increased from 17.5 to 19.3 per 1,000 in the three preceding weeks, declined again to 18.7 last week, and was 0.4 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 13.7 in Perth to 22.5 in Aberdeen. The zymotic death-rate in these towns averaged 3.2 per 1,000, the highest rates being recorded in Aberdeen and Dundee. The 238 deaths registered in Glasgow included 20 from diarrhoea, 5 from whooping-cough, 4 from scarlet fever, and 4 from diphtheria. Three fatal cases of "fever" and 2 of diphtheria were recorded in Edinburgh.

ENGLISH URBAN MORTALITY IN THE THIRD QUARTER OF 1895.

THE vital and mortal statistics of the thirty-three large English towns dealt with by the Registrar-General in his weekly returns are summarised in the accompanying table. During the three months ending September last, 82,001 births were registered in these thirty-three towns, equal to an annual rate of 31.1 per 1,000 of their aggregate population, estimated at rather more than ten and a half millions of persons in the middle of this year. In the corresponding periods of the three preceding years the birth-rates in these towns were 32.1, 31.5, and 29.8 per 1,000 respectively. In London the birth-rate last quarter was 31.4 per 1,000, while it averaged 31.5 in the thirty-two provincial towns, among which it ranged from 22.1 in Huddersfield, 24.4 in Halifax, 25.3 in Brighton, and 25.7 in Croydon to 34.4 in Preston, 35.3 in Gateshead, 36.2 in Salford, and 36.4 in Liverpool.

During the quarter under notice 52,278 deaths were registered in the thirty-three towns, corresponding to an annual rate of 20.2 per 1,000, against 17.9, 21.5, and 18.4 in the three quarters of the three preceding years, 1892-4. In London the rate of mortality was equal to 18.6 per 1,000, while it averaged 21.3 in the thirty-two provincial towns, among which it ranged from 12.8 in Croydon, 14.4 in Bristol, 15.0 in Huddersfield, 15.4 in Swansea, and 15.6 in Halifax to 25.5 in Manchester, 26.0 in Sunderland, 26.1 in Wolverhampton and in Preston, 27.2 in Salford, and 28.2 in Liverpool. The 52,278 deaths registered in the thirty-three towns last quarter included 12,134 which were referred to the principal zymotic diseases, equal to an annual rate of 5.0 per 1,000; in London the zymotic death-rate was equal to 4.3 per 1,000, while it averaged 5.5 in the thirty-two provincial towns, and ranged from 1.8 in Plymouth, in Bristol, and in Huddersfield, 2.1 in Halifax, 2.2 in Croydon and in Swansea, and 2.9 in Brighton to 7.8 in Salford, 7.9 in Bolton, 8.1 in

Sunderland, 8.4 in Blackburn and in Preston, and 8.7 in Hull. The 13,134 deaths referred to the principal zymotic diseases in the thirty-three large towns included 3,892 which resulted from diarrhoea, 1,364 from measles, 567 from diphtheria, 585 from whooping-cough, 857 from "fever" (principally enteric), 854 from scarlet fever, and 53 from small-pox. The 3,892 fatal cases of diarrhoea considerably exceeded the number recorded in the corresponding period of last year; in London the death-rate from this disease was equal to 2.49 per 1,000, while it averaged 4.10 in the thirty-two provincial towns, among which diarrhoea showed the highest proportional fatality in Leicester, Bolton, Salford, Preston, Sheffield, Hull, and Sunderland. The deaths referred to measles, which had been 512 and 1,173 in the two preceding quarters, further increased to 1,346 during the three months ending September last; in London the measles death-rate was 0.69 per 1,000, while it averaged only 0.36 in the thirty-two provincial towns, among which this disease was proportionally most fatal in West Ham, Manchester, Salford, Oldham, and Blackburn. The fatal cases of diphtheria, which had declined from 1,058 to 761 in the three preceding quarters, rose again to 907 during the three months under notice; in London the death-rate from this disease was as high as 0.55 per 1,000, while it averaged 0.36 in the thirty-two provincial towns, among which diphtheria showed the highest proportional fatality in West Ham, Wolverhampton, Cardiff, Birkenhead, Salford, and Burnley. The deaths from whooping-cough, which had been 1,145 and 1,392 in the two preceding quarters, further declined to 805 during the three months ending September last; in London the death-rate from this disease was equal to 0.24 per 1,000, while it averaged 0.35 in the thirty-two provincial towns, and was highest in Wolverhampton, Liverpool, Bolton, Bradford, and Gateshead. The deaths referred to different forms of "fever", which had declined from 654 to 324 in the three preceding quarters, rose again to 517 during the quarter ending September last; in London the "fever" death-rate was equal to 0.15 per 1,000, while it averaged 0.23 in the thirty-two provincial towns, among which "fever" showed the highest proportional fatality in Liverpool, Bolton, Salford, Burnley, and Sunderland. The fatal cases of scarlet fever which had declined from 658 to 351 in the six preceding quarters, rose to 514 during the three months under notice; in London the death-rate for this disease was equal to 0.38 per 1,000, while it averaged 0.17 in the thirty-two provincial towns, and was highest in Wolverhampton, Liverpool, Manchester, and Salford. The deaths referred to small-pox in the thirty-three towns, which had been 39 and 15 in the two preceding quarters, rose again to 53 during the three months ending September last, of which 31 were registered in London, 17 in Oldham, 2 in Liverpool, 2 in Manchester, and 1 in Preston.

Infant mortality in the thirty-three towns, measured by the proportion of deaths under one year of age to registered births, was equal to 252 per 1,000 last quarter, against 185, 250, and 169 in the corresponding periods of the three preceding years. In London the rate of infant mortality was 222 per 1,000, while it averaged 272 in the thirty-two provincial towns,

among which it ranged from 141 in Bristol, 157 in Huddersfield, 166 in Halifax, and 177 in Swansea to 235 in Bolton, 250 in Leicester, and in Preston and in Hull, 257 in Wolverhampton, and 270 in Burnley.

The ranges of 641, or 1.2 per cent., of the deaths in the thirty-three towns during the third quarter of this year were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths in London did not exceed 0.8 per 1,000, while it averaged 1.6 in the thirty-two provincial towns. The causes of all the deaths during the quarter in Croydon were duly certified; in the other towns the lowest proportions of uncertified deaths were registered in Plymouth, Nottingham, Derby, Bolton, and Oldham, and the highest in West Ham, Birmingham, Liverpool, Huddersfield, and Sheffield.

MILKBORE DIARRHOEA.

AN outbreak of milkborne disease in the city of Manchester at the close of last year finds record in the annual report of Dr. Niven. The malady was characterised by diarrhoea, sickness, and abdominal pain. The cases, so far as could be ascertained, numbered 100 in 41 houses, or just to per cent. of the houses served by one and the same milk canner. No case proved fatal, but the occurrences were over within the space of a few days in early November. It was soon seen that the milk supply was a community of condition so far as all the patients were concerned, and it was discovered that raw milk drinkers were the chief sufferers, though one lady was positive as to the boiling of the milk in her affected household, and it had been warmed, as in tea and coffee, in other cases. A typical household may be quoted: Three attacks, four escapes; three attacked had unboiled milk; of the escapes, two never used the milk, one took it only boiled, and the fourth only in tea. Dr. Niven visited the farm whence the milk came, and found that it was the milk of that farm, and not the added milk from a more distant farm which supplemented the farmer's stock that had caused the epidemic, the home farm milk only being sent into the affected district. Near the farm were also two privy middens; two streams ran near the farm, one being fouled by the drainage of the tip, and the other being contaminated by sewage. The water used for washing the pails was kept in a foul cistern, and was used in a tepid state; and the cows drank from a pool which received the drainage from the cowshed midden. The stored milk could be contaminated by the emanations from the cowshed. A sample of the milk tested bacteriologically showed a bacillus having the characters of the coli communis. It was with difficulty that lists of customers could be obtained from the farmer, and in circumstances which threw doubt on their correctness. The farmer for a time suspected the fact that at the dates when the milk must have been infective he had a cow suffering from garget, and that he had her removed from the farm and slaughtered for food before Dr. Niven heard of the facts. Later on the farmer volunteered information that showed that the period of the cow's greatest illness coincided with the period of epidemicity of the malady, and he himself ascribed the outbreak to the milk of this cow being mixed with

Analysis of the Vital and Mortal Statistics of Thirty-three of the Largest English Towns during the Third Quarter of 1893.

Towns.	Estimated Population beginning of 1893.	Births.	Deaths.	Annual Rate per 1,000 Living.			Deaths from Principal Zymotic Diseases.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping-Cough. the general supply from his sheds. The evidence given by the farmer was, however, very misleading, and information was forthcoming to show that the locality hit by the disease was almost wholly supplied by the implicated farm, and almost wholly affected in its constituent houses. Indefinite as the facts are as to the precise cause of the condition of the milk which induced illness in its consumers, Dr. Niven points out that all the factors for rendering the milk infective were present at the farm and its surroundings, and that the presence of the bacillus coli communis at least demonstrated the contamination of the milk by excremental matter.

TUBERCULOUS CATTLE.

It is an abuse of the tuberculin test brought to notice by Mr. M'Connell, M.R.C.V.S., is becoming as common as he represents, legislation is urgently needed. In a letter to the *North British Agriculturist*, he says that the test is being "pretty extensively employed" by owners of cattle to detect tuberculous animals, those in which disease is indicated being generally drafted out from the healthy ones, and sent to the public markets for sale. Suppose that twenty tuberculous cows are found in a herd and thus disposed of, they may be spread about over twenty different farms, carrying contagion to each herd, in which one of them is placed. Mr. M'Connell admits that a few public-spirited stockowners are making a proper use of the test by isolating cattle found diseased and fattening them off, but they, he adds, are the rare exceptions. He mentions a case in which nearly three-fourths of a herd of cows, 94 in number, were found to be tuberculous, and all, or nearly all, sent to the markets and sold. There should be a very heavy penalty on the sale of a tuberculous animal known to be thus diseased, in order to check the atrocious practice to which Mr. M'Connell calls attention; and equally necessary is a penalty on the sale of milk from a cow known to be tuberculous; but if legislation went no further than this it would do little besides partially stopping the use of the tuberculin test, which it is desirable rather to encourage, if not to make obligatory. Compensation for condemned animals, and the inspection of those fattened when they are slaughtered, must also be dealt with in any legislation intended to protect the public against the terrible risk of infection from tuberculous meat and milk to which they are at present exposed.

PAYMENT WITHOUT RESULTS.

THE Whitstable Urban District Council, having withdrawn from the East Kent combination, have had to decide upon the salary to be paid to their future medical officer of health. At first they assessed the value of his services at £20 per annum, but this was advanced to £200. Now the Local Government Board have declined to approve of anything less than £400, and the district council have finally decided, by a majority of six to three, to revert to the original sum of £20, and pay the whole out of the local rates. This is an odd decision in some respects, since it leaves the Whitstable ratepayers no better off than if the Local Government Board proposition, with its corollary of repayment of half the salary out of county funds, had been accepted. It simply deprives their officer of that half of his proper salary which does not come out of the local rates, and the intending candidates for the not very lucrative appointment will doubtless take note of this. It ought to be added, however, that there seems to be something exceptional in the working of the Public Health Act in Whitstable, for one of the councillors, who certainly ought to know, urged in justification of the reduced salary the unexpected argument that all the medical officer of health had to do was to certify cases of infectious disease. Nowhere else does this unusual responsibility fall to the lot of the health officer, much less constitute his whole duty, and the Local Government Board would probably have a good deal to say if this view were put into practice. But however little the majority of the district council may intend their officer to do, their decision ought to be popular with neighbouring councils, for Whitstable has to contribute its share to the county funds out of which half the salaries of the health officers of other districts are repaid, although it prefers on high economical grounds to take nothing in return. The economy may not be altogether apparent, but there is the decision.

EDINBURGH MILK SUPPLY.

CONSIDERABLE doubt has of late been felt and expressed as to the legal powers of the local authority of Edinburgh to regulate the milk supply of the city, especially that coming from entirely outside sources. The Town Clerk has now prepared a report, in which it is stated that the local authority—the magistrates and council—has ample powers to maintain a constant and systematic inspection, and to take measures for enforcing proper accommodation for cows, cleanliness in the utensils and premises connected with the milk trade, and immunity from contamination by infectious disease within the city. As to the regulation of milk supply coming from places further than the city boundaries, the report runs:

"In cases where milk is supplied within the city, coming from byres outside the city, the inspectors (under the 1891 Act) can at all times enter these byres and inspect and examine the cows therein; and, in the event of any animals suffering from tuberculosis or any disease which might render the use of their milk dangerous or injurious to health, the owner must put away the animal at once, or cease altogether to supply milk to the city. If he continues to supply milk to the city and retain the diseased cow, he is presumed to be selling his milk, and may be punished accordingly. Where milk is coming into the city from farms or other places outside the city, and infectious disease breaks out among persons residing thereon, in such circumstances as the inspector considers imply risk of contamination, the magistrates can issue an order prohibiting any milk from entering the city from any such place until it is certified free from infection."

It is suggested that the local authority should now specially appoint the medical officer of health, and those present inspectors of markets who are qualified veterinary surgeons, for the purpose of inspecting and examining so as to prevent milk being supplied from cows suffering from tuberculosis.

Further, an arrangement ought to be come to with the county autho-

rities so as to get immediate intimation of cases of infectious disease. To the same and milk dealers should be asked to co-operate.

There now exists an overlapping of authority and of officials which does not tend to the public good. Therefore the whole subject of the appointment of inspectors should be reconsidered and adjusted.

PREVALENCES OF FILTH DISEASE.

ACCOUNTS reach us from various centres of local prevalence of enteric fever, and all of them relate circumstances which are far from complimentary, either to the districts concerned or to the health bodies of those districts. Thus, from Ribby rural district comes the story of enteric fever prevailing at Enderby, of the local hospital being full, of many other cases unattended in the houses in the village, of an overworked inspector, and of the place dependent on wells for its water supply, many of them, it is feared, containing unwholesome water, to the drinking of which the disease prevalence seems to be ascribed. Another local epidemic ascribed to the agency of drinking water is at Clayton-le-Moors in Lancashire, where a score of cases have occurred, and where there has been dissatisfaction for some time as to the quality of the water, especially since the reservoir has been low. One danger to the water system is that many farms are situate on the gathering ground, though no fault has seemingly been found with any at present. A prevalence of a somewhat different type is that at West Bromwich, where the Board of Guardians have passed a resolution calling the attention of the town council to the disgraceful condition of the property in which cases of typhoid fever are arising. The action of the health authority has been called in question, and reprimandations have been freely made as to the insanitary state of house property held by guardians and council members. Added to these facts there have been several fever patients taken to the workhouse, and thence to the Poor-law infirmary, and we learn that the town council have themselves no isolation hospital to which cases of infectious disease can be removed. It is the old story over again of unpreparedness for the sickness which comes sooner or later to the district, which is not ready for the prompt isolation of the earliest cases, by which means death, suffering, and the rates are so often saved, and the good name of a locality spared. Filth, whether of air, water, soil, and lack of means of combating disease when present will ever be the forerunners of disease and distress.

EMERGENCY AT CAMBORNE.

THE story comes from Camborne to the effect that scarlet fever is prevailing there and that there being no hospital accommodation the affected are living in houses where the isolation is of the most elementary character, the neighbouring children, indeed, running in and out of the infected houses with impunity. But the urban District Council seem none the less satisfied to let the matter of the provision of hospital accommodation be decided by the "views of the ratepayers" instead of proceeding to the question at once with a view of staying the present mischief, even if it be by some temporary method. Greatly as we are opposed to temporary hospitals there are times when it is unwise not to take the matter up as an emergency expedient, and since the council are looking to the item of expense as standing in the way they had best consider the cost of the alternative of a do-nothing policy and see which is likely to be the dearer to the pockets of the ratepayers.

HOSPITALS FOR INFECTIVE DISEASES IN IRELAND.

LAST week a meeting of representatives of various sanitary authorities was held in Dublin, under the presidency of the Lord Mayor, for the purpose of considering a scheme for the erection of hospitals for infectious diseases in the County Dublin. Sir Charles Cameron and Dr. Stafford, Local Government Board Inspector, addressed those present, and pointed out the importance of having cases of infective disease treated outside the city. A subcommittee was appointed to consider the scheme, and to report upon it to a general meeting.

THE COVENTRY BOARD OF GUARDIANS AND THEIR DISTRICT MEDICAL OFFICER.

WE learn from the *Coventry Standard* that at a recent meeting of the guardians there was a long and animated discussion as to the adoption of the report of a committee which had been appointed to consider the question of remuneration of the three district medical officers, and had recommended an increase from £63 to £80 a year each. It appears that since these stipends were fixed—thirty-five years back—the population has increased almost 60 per cent.; and, although this has been the case, the increase of salary recommended was only about 25 per cent. of that hitherto paid. It could hardly have been expected that this recommendation would have met with any opposition whatever. It is difficult to see on what grounds the increase of salary recommended by the committee should have been so small; there may, however, have been some reason for this which to us is not apparent. It is, however, satisfactory to find that, notwithstanding the strenuous opposition of four members of the Board, the recommendation of the committee was carried; and this will soon, doubtless, be sanctioned by the Local Government Board. The majority of the Coventry guardians appear inclined to make progress in the right direction, but we fear they require a little more pluck.

SMALL-POX IN BRISTOL IN 1890-4.

E. D. S.—Dr. Davies speaks of "99 cases occurring in sequence," but he nowhere leads to the supposition that there were other cases dealt with in his able and detailed report on the epidemic.

NOTIFIED CASES IN COMMON LODGING HOUSES.

R. T.—We should certainly regard a private medical practitioner notifying cases under the Infectious Disease (Notification) Act in persons who, being destitute, were lodged in common lodging houses, as entitled to the higher fee of 2s. 6d., such cases not being in any sense located in a "public institution," whatever may be the ultimate destination of the pauper patients.

THE ARGUMENTS OF ANTI-VACCINATORS.

VACCA.—In addition to Mr. Ernest Hart's book on *Trustworthy Vaccination*, Dr. J. C. McVie's work on *Vaccination* published in Cassell's *Illustrated Encyclopedia* will be sent with advantage, the fallacious anti-vaccinators being well exposed in its admirable pages. The reports of the Royal Commission on Vaccination, so far as issued, can be obtained from Messrs. Eyre and Spottiswoode, East Harding Street, E.C., but we believe we are right in stating that the issued volumes only contain the evidence given prior to 1896.

INDIA AND THE COLONIES.

INDIA.

CHOLERA AND CONTAMINATED WELL. **WATKE.**—In the report on the sanitary administration of the Punjab for the year 1897 Dr. Mulrony, Civil Surgeon, furnishes interesting particulars of a limited outbreak of cholera in the villages of Batoki and Pakhpura, in the Amritsar district. The connection with the water supply is well brought out. A woman of Batoki drank from a shallow pool which, from its position on the roadside, was liable to contamination by passing pilgrims. About thirty hours thereafter she was seized with cholera. On April 25th her soiled clothes were washed on the parapet of one of the two village wells. On April 30th cholera broke out among those of the villagers supplied from this well, those who got their water from the other well being exempt. From April 30th to May 5th there were in all 49 seizures with 13 deaths. After that date the disease ceased. Half a mile from Batoki lies Pakhpura. On May 5th a woman from Pakhpura paid a visit to Batoki and drank from the contaminated well. The same day she returned to Pakhpura. On May 6th she was attacked with cholera and died. While she was ill her son washed her soiled clothes on the parapet of one of the three village wells. On the following day, May 7th, cholera broke out among those who drank from this well. During the night six were attacked, all of whom died. On May 8th 8 were attacked, of whom 2 died. That day the well was closed. All those attacked had drunk from the contaminated well, those who drank from the other wells in the village escaped.

SCHEME OF MEDICAL ORGANISATION.—The following circular has, says the *Times* of India, been issued by Messrs. Bhaichandra Krishna, J. A. Ba Gama, N. H. Chokney, and Khoja Abdullah, Honorary Secretaries of the Bombay Committee for Medical Reform in India:—"The movement for medical reform in India for a reparation of the Civil and the Military Medical Services, with reconstitution of the civil branch and advancement and proper recognition of its subordinate grades, having enlisted general approval and sympathy, both in India and in England, it has been the feeling of several members of the profession in India and their friends in England that the time has arrived for a united and sustained effort to secure success to this movement by a thorough organisation. The objects the reform aims to attain are, as is now well known, catholic in character, and comprise not only the good of the Indian profession in its various grades, but also the interest and welfare of the public at large and the taxpayer in particular, who would be materially relieved of a considerable portion of the burden of the present military charges. The reform seeks to throw open to the profession at large, and the Indian profession in particular, the fields and opportunities of scientific work which have hitherto been denied them. A fair head and no favour to talent wherever found, and merit and special training—the only passport to seats of learning and scientific work—are the guiding principles of the proposed reform. It seeks to completely do away with the great evil and mischievous now at work in the medical administration of the country, and which is the result of a system which, in the words of Mr. Ernest Hart, is radically wrong, the Indian Medical Service man being expected by Government to be fit for any post that may be vacant, a system in which men work their way up by seniority to positions for which they are quite incapable. To compass these ends the reform advocates: (1) Separation of the civil from the military medical service of the country, with the formation of one military medical service for India, divided into a European army branch and a native army branch, and in fact the military members of the Indian Medical Service are at present under the orders of the head of the European branch medical service called the Army Medical Service. (2) Reorganisation of the Civil Medical Service, reconstituting it as a purely civil medical service recruited from the open profession of medicine, with a due leaning towards the utilisation of indigenous talent and proved merit and ability, other things being equal. (3) Proper recognition and advancement of the civil assistant surgeons and hospital assistants, and their absorption into the Civil Medical Service of India. In order to bring about these results both time and money are required; a sufficiency of funds will ensure the desired permanent agitation so necessary to the success of every reform movement. It is proposed to agitate the matter, both in India and in England, by representations in proper quarters, and by sending a delegate to England, who would place before the British public, the profession, and the authorities the case of the profession in India, and enlist their sympathy and co-operation in securing the favourable attention thereto of those in power in England. The House of Commons will be appealed to, and it is confidently hoped that it will not be long before some at least of the reforms set forth above are taken up and carried out. In order to make the movement thoroughly representative of the Indian profession, local committees, styled the Bombay, Calcutta, Madras, and Lahore, etc., committees for medical reform in India are being organised, and a fund called the Indian Medical Reform Fund has been started. The funds collected by the several committees will be amalgamated into one general fund, and the same will be utilised to the best advantage towards the objects of the reform as above set forth. It is gratifying to notice in the *INDIAN MEDICAL JOURNAL* of July 1898 that the organ of the British Medical Association is convinced that our reform programme must sooner or later be adopted. And soon after this has come the glad and reassuring cable message of a warm advocacy of the reform by the British Medical Association at their annual meeting

in London on August 1st. Such influential support will, no doubt, lighten our work and hasten action by the authorities. A summary of the whole programme endorsed by the *BRITISH MEDICAL JOURNAL* in their primary given in its issue of July 1898: (1) The need of putting a stop to military surgeons going into civil employ or duty. (2) To cause all military surgeons now in civil work to return to military duty. (3) To throw the so-called "expert" or "specialist" posts and leading appointments open to competition in India and in England. (4) To instal the un-covenanted as the nucleus for the Indian Civil Medical Service, and to fill up all civil vacancies from the special addresses that will be made to this service. (5) To utilise military surgeons and assistant surgeons with British and Indian troops under a central organisation, which is tantamount to the amalgamation of the Army Medical Staff and Indian Medical Service. This appeal, the outlines of which were settled at a preliminary meeting held on July 3rd last, were unanimously adopted at a well-attended meeting of members of the local profession held on September 15th, and it was resolved thence to solicit the support of all friends and well-wishers of our movement. Your cordial co-operation is earnestly requested, and you will, we feel sure, assist and advance this movement with your subscription and your influence."

SANITARIUM FOR WOMEN.—A project, which promises to be of substantial utility, says the *Times* of India, has just been brought to a successful issue. Some time since Mr. Fordey Pilson formulated a scheme for establishing a sanitarium for women and children at Nasik, a station which recommends itself by its dry bracing climate to convalescents from Bombay, inasmuch as it is available in the rains as well as in the fair season. Nasik, indeed, is so favoured a site that in Mr. George Campbell's days an effort was made to persuade the Government of India that its permanent capital should be located there. Instead, however, of having a Government house at Nasik we have now an at least equally well located institution in the shape of a group of cottages occupying an area of ten acres, which has been presented by Mrs. Pilson and intended to serve the purpose of a home for convalescents from Bombay. The cottages have been provided at the cost of a number of friends of various communities whom Mrs. Pilson has been able to associate with her in the good work, for as the institution is intended to benefit Europeans, Hindus, Parsees, and Mohammedans alike so people of all those races have come forward to provide funds. The cottages are now ready for occupation by convalescents, not by sick persons. They are offered rent free, two of them being available for Europeans, two for Parsees, three for Hindus, and three for people of other races. It is an interesting experiment which has thus been set afoot, and it may be expected to be of real service to people who are ill situated for providing themselves with the particular advantages which it offers.

ASSAM DISPENSARIES.—**SURGEON-MAJOR A. STEPHEN, M.B.**, in his report on hospitals and dispensaries in the province of Assam for the year 1897, shows that progress is being made in providing medical relief for the inhabitants of this sickly territory. About half a million of patients were treated in 93 institutions, the cases treated representing about 7 per cent. of the population of the province. About one fifth of the patients suffered from malarial fevers, and another fifth from skin diseases. Intestinal worms, rheumatism, ulcers, bowel complaints, and spleen constituted large numbers. The disease called *k'ia-sagar* (the black sickness) which is thought by some to be a malignant type of jaundice, and by others a result of ankylostomiasis, prevails severely in some places, and special dispensaries have been opened for the treatment of this malarial. Five hundred and eleven surgical operations were performed in the dispensaries, with a death rate of 8.5 per cent. It is noteworthy that 26 of these were obstetric. Eye and stone operations are rare in Assam, and there is no operation for elephantiasis in the list. Local bodies contribute largely to the support of these institutions. The Government of the provinces supplement local effort generously.

ENTERIC FEVER.—Some cases of enteric fever, says the *Indian Daily News*, still appear in Cawnpore. A short time ago two girls in the High School died from this disease, and during the past week there have been two more fatal cases among girls, though not in the school. All the cases have occurred in continents, though reported to be the healthiest part of the station.

SANITARY NEEDS OF INDIA.—The most conspicuous feature of the report for the past year of the Sanitary Commissioner for the Central Provinces is, says the *Times* of India, the mortality from fever. The total number of deaths was 363,000, or considerably more than 100,000 in excess of the figures for 1896, and out of this total 160,000 deaths are attributed to fever, an increase in twelve months of nearly 50 per cent. These figures aptly illustrate Brigade Surgeon Lieutenant-General H. H. Clouston's contention that, under the existing system, matters are going from bad to worse, and that disease, and especially enteric and malarial fever, is obtaining the mastery. When the mortality from this source alone is more than double that from all other causes combined, it is surely time to ask for very careful inquiry with a view to finding a remedy for so startling a state of affairs, for it seems tolerably certain that a large proportion of these cases were remedial had proper precautions been adopted. "Fever," which is generally regarded with such horror, was not responsible for one-fourth of this excessive mortality, while the deaths from dysentery and diarrhoea numbered less than 17,000. Strangely enough this unprecedented fever mortality is not commented upon in the Sanitary Commissioner's report, and receives only the barest mention in the Government resolution on the report. It was almost as if it had been taken for granted, and that there was really nothing out of the way about a mortality which carried away 50 per cent. of the population. The local Government observe that the report is "deficient in fact and information," and that it is hard to gather from it a comprehensive view of the whole scope and progress of sanitary work during the year. It is, indeed, for the sanitary condition of the towns, villages, and towns throughout the whole province is distributed by a bad drainage system.

COMMISSIONED MEDICAL OFFICERS FOR NIAS. **SARAWAY.**—The *Times* of India announces that the British Government, with the Government of Madras has suggested that the administrative control in all island railways should be a commissioned officer, belonging to the Indian Medical Service, so that the number of military medical officers at the disposal of the Government of India as a war reserve may be increased. This suggestion has been approved by the local government, and, in the event of

its sanction by the Government of India, the East Coast Railway will have a commissioned medical officer as its chief medical adviser.

Ceylon.

SANITATION IN CEYLON.—It is interesting to observe from the *Ceylon Herald* how frequently the debates in the Ceylon Legislative Council turn upon sanitary matters. Among other affairs which have been brought forward we note the endorsement made by Dr. F. D. Antonicus to establish a sanitary department for the purpose of organising measures conducive to the prevention of the spread of contagious diseases in the island. If the statements made by him are to be accepted as representing the actual state of affairs, there can be little doubt that a reform is necessary, yet, apparently under guidance of the Colonial Secretary, the motion was negatived. It is difficult to understand the complacency with which the existence of outbreaks of disease among the natives is sometimes regarded by those in authority. The Colonial Secretary is reported to have said: "I think from the opinions formed from the frequent reports and the experience of a small-pox epidemic in another colony, that we have passed through the epidemic fairly well, considering the densely-populated and closely-packed character of this town. There were about 1,700 cases only, about half of which proved fatal." He ended by saying that there was no want of power on the part of the medical authorities, and that he did not see the necessity for the appointment of another Board. But no attempt was made to controvert the statement of Dr. Antonicus that great and overwhelming as were the powers of the authorities they were not exercised. Especially was this the case in regard to vaccination and revaccination, the performance of which he urged as being even more important than the provision of enlarged hospital accommodation.

THE INDIAN PRESS ON MR. HART'S ADDRESS.

A CORRESPONDENT signing himself "Verax" writes to the *Pioneer* advertising to the articles which appeared on September 6th and 8th, and quotes the cases of Surgeon Major de Renzy, Sanitary Commissioner, Punjab, and Dr. Furnell, Sanitary Commissioner, Madras, as supporters for advancing the waterborne theory of cholera. The writer also draws attention to the fact that Dr. Cunningham's report of 1879 concludes the opinions advanced by him on cholera in 1867, a point not clearly indicated in the *Pioneer* articles.

HOSPITAL AND DISPENSARY MANAGEMENT.

GLAMORGAN COUNTY ASYLUM.

OVERCROWDING is hampering this Asylum Committee in their efforts to keep the institution in a proper state of repair, and despite the opening of a male infirmary, the pressure upon the accommodation continues. Dr. Pringle, in referring to this want of room, says the evils of overcrowding are so serious, involving as they do impairment of health, and lessening of the powers of resistance to disease, as well as causing irritability and quarrelsomeness, and rendering the management of the patients more difficult, that it is better to have too much room than too little for those who are unable to help themselves. That this must be a serious question is emphasised by the fact that wards that have only proper accommodation for sixty patients are now occupied by ninety. Any surplus accommodation provided could be immediately, and very profitably, occupied by private and out-county patients, and the necessary separate treatment for idiots and imbeciles. The average daily number resident during the year was 1123.7, while the admissions reached the high total of 291. The percentage of recoveries on the admissions was 24.6, and the death-rate was 7.6 upon the total number under treatment. General paralysis seems greatly on the increase, for whereas in the five years 1889-93 this form of disease constituted 7.6 per cent. of the admissions, during the last five years the proportion has risen to 15.2, and, as Dr. Pringle points out, this increase is half as great again in females as in males. This increase is serious, and compares most unfavourably with the asylum statistics in England and Wales, the proportion he states being 15 for males and 3.7 for females in a total of 9.1. The Commissioners in their report express their feeling of great satisfaction at the amount of work the Committee have undertaken and are still undertaking in their efforts to ameliorate the condition of the lunatics belonging to this county.

THE EAST RIDING ASYLUM, BEVERLEY.

THE average number of patients daily resident during the year ending March 31st last was 545.25, namely, 17.35 private patients, 2.48 out-county patients, and 545.25 East Riding patients. The average cost per head per week for their maintenance was only 8s. 6d. per week. The general health of the patients has been satisfactory and the buildings in good condition. Eighty-six patients were admitted, including the 20 out-county patients from Northumberland, and Dr. Maclachlan very properly draws the attention of his Committee to the dwindling surplus accommodation of the asylum which must be supplemented ere long by the erection of new buildings. The recovery-rate was 23.33 of those admitted, and the death-rate 9.41 per cent. of the daily average number resident. No accident is recorded, and there was no outbreak of epidemic disease.

THE CITY OF LONDON LUNATIC ASYLUM.

DURING the year 1894 there were 385 patients under treatment at this institution, and 473 remained on the books on December 31st, showing an increase of 27 on the year. The average number daily resident was 468. There were 116 patients admitted; 66 were discharged, and 29 died. The recovery-rate was 25.32, calculated upon the admissions, and the death-rate was in the proportion of 6.18 per cent. upon the total number under treatment. No death is recorded as having resulted from accident or injury, and no inquest was necessary. The committee is to be congratulated upon the success attending the reception of private or paying patients, who numbered 97 at the close of the year. The throwing open

of the doors of the asylum for the admission of those who have by reason of illness become crippled in their resources is a humane and wise action, which is a boon to the community and at the same time a source of valuable income to the institution. The health of the patients was good, and Dr. Ernest White has every reason to believe that the low death-rate and excellent health of the patients is in no small degree owing to the fact that the institution is situated upon a most salubrious site. Later as an article of diet has been abolished and milk substituted with benefit to all concerned. The courses of lectures to the nurses and attendants have been continued.

KIRKLANDS ASYLUM.

THE annual report of the Kirklands Asylum for Glasgow, Govan, and Leamart gives the total number of patients under treatment for twelve months as 287, with a resident population of 230. The recovery-rate calculated on the admissions was 45.7 per cent. and the death-rate was 4.6 per cent. of the average number resident. Two cases of sudden death showed on post-mortem examination the cause to have been heart disease, and no serious accident occurred. Dr. Skene, the Medical Superintendent, gives an interesting account of the occurrence of a severe outbreak of influenza. A patient from an infected district, himself recovering from a severe attack was admitted with a cold throat, from attempted suicide. He was placed in the sick room and within a few days influenza broke out among the sick-room attendants and patients. This extended till there were 30 cases in bed at one time. Dr. Skene notes that although the sexes mixed freely at their meals and entertainments the epidemic did not appear on the female side of the asylum, which lends him "to conclude its greater communicability among persons sleeping together." Dr. Campbell Clark, who had been Medical Superintendent since the opening of the asylum, has recently been appointed to the new Lanark Asylum, and the Committee speak in high terms of his efficiency and ability while at Kirklands.

DUNOON CONVALESCENT SEASIDE HOMES.

THE twenty-sixth annual report of this institution is an excellent record of philanthropic work. During the year the homes have received nearly 4,000 persons, at an expense of over £7,000. The annual meeting was signalled by the intimation of a donation of £200 from Mr. Alexander Sinclair, of the *Glasgow Herald*, to endow a bed specially for the benefit of printers and others connected with publishing, Mr. Sinclair taking the opportunity of the completion of 50 years' connection with the *Glasgow Herald* to do this generous act.

MEDICAL NEWS.

DR. W. S. HEDLEY has been appointed medical officer in charge of the Electrical Department which has been formed at the London Hospital.

MR. HENRY HARBEN has presented a cheque for £1,000 to the funds of the North London Hospital for Consumption at Hampstead. This is the second donation of a similar amount from Mr. Harben to the hospital.

MR. HARDINGE FRANK GIFFARD, barrister-at-law, has been appointed Secretary to the Commissioners in Lunacy in the place of Mr. George Urmson. The post is worth £800 a year. Mr. Giffard is a member of the Inner Temple, was called to the Bar in 1887, and is attached to the North-Eastern Circuit.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The autumn general meeting of this Association will be held at the Café Monico, 6.30 P.M., Tuesday, November 12th. The autumn dinner at the Monico the same evening at 7 P.M. The Lord Chief Justice of England will be the guest of the Association.

DAVID JAMES GRAHAM, M.B., C.M., (James Scott Scholar of the University of Edinburgh), and Robert William Beesley, M.B. and C.M. (Buchanan Scholar), have been appointed house-surgeons to the Edinburgh Royal Maternity and Simpson Memorial Hospital for the quarter beginning November 1st.

MR. B. I. BARNATO and several other friends have sent to the Lord Mayor, through Mr. H. C. Burdett, cheques for £15,000, £1,000 of which is to go to the Hospital Sunday Fund, £200 to the Hospitals Association for the establishment of a reference library on all subjects connected with hospitals and charities, and the remainder to other indicated charities.

THE CHOLERA.—Up to the evening of October 16th there had been altogether 18 cases of cholera and 9 deaths at Damietta. The disease is said to be of a mild type. Cordons have been established wherever a case has occurred, so that each centre of infection is isolated. The Turkish authorities have imposed ten days' quarantine on all arrivals from Damietta. On October 21st there were 2 further cases at Damietta, while at El Menzalah and its vicinity there were altogether 30 cases

and 12 deaths on October 20th and 21st. The cases have only occurred among the poorest class of the city. The cholera is reported to be gradually decreasing in intensity throughout the whole of the southern provinces of Russia. On October 21st and 22nd there were 23 further cases of cholera and 10 deaths at El Menzalah.

THE PATHOLOGICAL SOCIETY OF MANCHESTER.—The annual meeting of this Society was held on October 9th at Owens College Medical School, Professor Sheridan Délepine in the chair. The following officers were elected for the session 1895-96: *President*: H. R. Hutton, M.B. *Vice-Presidents*: T. Harris, M.D.; W. Thorburn, F.R.C.S. *Treasurer*: T. N. Kelyack, M.D. *Secretary*: R. B. Wild, M.D. *Committee*: A. Brown, M.D.; T. A. Goodfellow, M.D.; A. T. Helme, M.D.; E. T. Milner, M.B.; E. S. Reynolds, M.D.; W. P. Stocks, F.R.C.S.; A. T. Wilkinson, M.D.; J. B. Wolstenholme, F.R.C.V.S. *Auditors*: D. Headridge, L.D.S.; J. W. Smith, F.R.C.S.

It has been determined to postpone the final interment of M. Pasteur, which was to have taken place at the Pasteur Institute on October 20th, the date of the centenary of the French Institute. It was thought that on the occasion of the centenary of the Institute many of the foreign members might also wish to take part in M. Pasteur's funeral. It is now found, however, that the vault and some of the sculpture cannot be ready in time. Many of the learned societies in Great Britain had determined to send delegates to the funeral. Lord Kelvin was to represent the Royal Society, Sir Joseph Lister and Sir John Evans intended also to be present, and Sir William Priestley was to represent the University of Edinburgh.

In his sermon at the celebration in St. Paul's Cathedral of the thirty-first anniversary of the Guild of St. Luke, the Bishop of St. Andrews referred to the value of the Medical Mission. He expressed the fervent hope that the result of the festival might be, not only liberal subscriptions, but also a large accession of members, drawn not from the clergy and nurses only, but from the medical profession. The preacher paid an eloquent tribute to the skill and self-sacrifice of the medical profession, and the love and gentleness of the nurses. The offertory was partly devoted to the Medical Missionary Fund of the Guild.

HOSPITAL SUNDAY FUND.—Mr. Henry C. Burdett, the secretary of the Loan and Share Department of the Stock Exchange, handed on October 22nd to the Lord Mayor a cheque for £3,400 collected in the Stock Exchange, through Messrs. Burdett and Harris and Messrs. Pim, Vaughan and Co., on behalf of the Hospital Sunday Fund, in response to the appeal recently made in the *Hospital* newspaper. This contribution raises this year's fund to over £50,000, a sum never before received since its foundation in 1873. This result also enables the council to claim the promised additional contribution of £100 from Mr. T. A. Denny. The Lord Mayor requested Mr. Henry C. Burdett to return his sincere thanks to the donors, and congratulated him on his own indefatigable efforts in the interests of the fund.

PRINCESS CHRISTIAN paid a visit on October 19th to the Hostel of St. Luke, 16, Nottingham Place, W. Her Royal Highness was received by the Chairman, Canon Utterson, who, in describing the objects and the work of the Institution, stated that the purpose of the Hostel was to provide medical and surgical treatment and a nursing home for the clergy of the Church of England, their wives and their children. Three classes of patients were received: those who could afford to pay the usual fees of the medical men attending them and also for their board; those who could not afford the medical fees but could pay something for their board; and those who were admitted entirely free of payment. Since the establishment of the Hostel 112 patients had been received and 44 operations had been performed.

THE MUZZLING ORDER IN MIDDLESEX.—An order has been issued by the Clerk to the Middlesex County Council from the Council's offices, Guildhall, Westminster, establishing the following regulations: "1. No dog shall be allowed in or on any public place within the administrative county of

Middlesex unless such dog is muzzled with an efficient cage muzzle, so constructed as to render it impossible for such dog wearing the muzzle to bite any person or animal, but not so as to prevent it breathing freely or lapping water. 2. Any dog found without being muzzled in the manner prescribed will be liable to be seized by the police and detained. 3. Any dog so seized and not claimed within four days from the date of the seizure thereof shall be slaughtered or otherwise disposed of as the Executive Committee may think fit."

HORSE MEAT IN GERMANY.—Some interesting details have been furnished recently as to the preparation and sale of horse meat in Germany. It is asserted that in the large cities the consumption of horse flesh is almost as great as that of beef or mutton, whilst even in the small cities it is, despite prejudice, daily growing larger. In the big cities some of the shops are devoted exclusively to the sale of horse meat, which is used only by the poorer classes. The German artisan is finding out that at 3jd. per lb. horse meat provides him with a food described as excellent in every particular, and the supply is now scarcely equal to the demand. The German butcher used to procure worn-out horses at £1 to £2 each, but as the supply of animals of this type is exhausted he has now to pay £9 or £10. Hence, though the poorer classes have been attracted to horse meat because of its cheapness as compared with beef, the butcher has been compelled to advance his prices. It is contended that, as the horse supply of the United States is practically inexhaustible, and as horses can be raised in the West almost as cheaply as cattle, and can be slaughtered just as easily, also, that as they can be shipped across the sea much more cheaply than cattle, and can be sold, either on the hoof or dressed, at prices certainly not exceeding 3jd. per lb., horse meat can be sold at a price not higher than that which the German artisan has hitherto paid. The flesh is consumed in Germany both salted and smoked as well as fresh, and the American producer is able to supply it in all three conditions. The importance of the subject is obvious to the American exporter, whose beef and beef products are now excluded from the German markets, and to the horse breeder, whose invested capital at present brings in very unsatisfactory returns.

MEDICAL VACANCIES.

The following vacancies are announced:

- BELGRAVE HOSPITAL FOR CHILDREN**, 77 and 79, Gloucester Street, S.W.—Surgeon to Out-patients; must be F.R.C.S. Eng. Applications to the Honorary Secretary by November 3rd.
- BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN**.—Resident Medical Officer and Resident surgical Officer. Salaries, £20 and £25 respectively, with board, washing, and attendance at the Institution. Applications to the Secretary, Children's Hospital, Steelhouse Lane, Birmingham, by November 15th.
- BRISTOL HOSPITAL FOR SICK WOMEN AND CHILDREN**.—House-surgeon; doubly qualified. Salary, £200 per annum, with room and attendance (not board). Applications and testimonials, enclosed "House-surgeon," to H. Lawford Jones, Secretary, before November 6th.
- BROWN ANIMAL SANATORY INSTITUTION**.—Professor Superintendent. Salary, £200 per annum. Applications to the Registrar of the University of London, Burlington Gardens, W., by November 10th.
- CARLISLE DISPENSARY, Carlisle**.—House-Surgeon. Salary, £100 per annum, with apartments, not board. Applications to Mr. G. A. Lightfoot, Honorary Secretary, 14, Bank Street, Carlisle, by October 25th.
- CATERHAM ASYLUM**.—Second Assistant Medical Officer under Metropolitan Asylums Board. Must not exceed 35 years of age, and be registered and qualified to practise both medicine and surgery in England. Will be subject to annual election after the completion of his third year of office. Salary, £120 per annum, rising to £150. Forms of application may be obtained at the offices of the Board, Norfolk House, Northumberland Street, W.C. Applications and testimonials to T. Duncombe Mann, Clerk to the Board, before October 30th.
- CITY OF DUBLIN HOSPITAL**.—Visiting Surgeon. Applications to Mr. Arthur Benson, F.R.C.S.I., Hon. Sec. Medical Board, City of Dublin Hospital, Upper Baginot Street, Dublin, before November 15th.
- GLASGOW MATERNITY HOSPITAL**.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 100, Buchanan Street, Glasgow, by November 15th.
- HORNCASTLE URBAN DISTRICT COUNCIL**.—Medical Officer of Health. Appointment for one year. Salary, £200 per annum. Applications to John Denton, J.P., Chairman of the Council, by October 31st.
- HOSPITAL FOR SICK CHILDREN**, Great Ormond Street, Bloomsbury, W.C.—House-Physician and also House-Surgeon; unmarried. Appointment for six months. Salaries, £200 each, with board and residence in the hospital. Applications and testimonials to the Secretary before October 25th.

HULL BOROUGH ASYLUM.—Assistant Medical Officer. Must be registered, unmarried, and not more than 30 years of age. Salary, £500 per annum, with board (no liquor), lodging, and washing. Applications and testimonials, endorsed "Asylum Medical Officer," to the Town Clerk, Town Hall, Hull, by October 31st.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.—Non-Resident Assistant Medical Officer. Salary, £250 per annum. Applications to R. Stonex, Secretary, 23, St. Mary's Gate, Manchester, before October 31st.

LIGHTHOUSE HOSPITAL FOR INFECTIOUS DISEASES. Shettleston, near Glasgow.—Resident Physician: duly qualified and registered. One with Public Health qualification and a knowledge of Bacteriology preferred. Salary, £150 per annum, with board, lodging, washing, and attendance. Applications and testimonials to W. H. Hill, Clerk to the Joint Committee, 104, Ingram Street, Glasgow, by October 31st.

LIVERPOOL EYE AND EAR INFIRMARY.—House-Surgeon: doubly qualified. Salary, £200, with residence and maintenance. Applications to R. Hugh, Hon. Sec., Bersey's Buildings, George Street, Liverpool, by November 2nd.

NORTH WEST LONDON HOSPITAL, Kentish Town Road.—Resident Medical Officer and Assistant Resident Medical Officer. Appointments for six months. Salary at the rate of £50 per annum attached to the senior post. Applications to Alfred Craske, Secretary, by October 28th.

ROYAL BERKS HOSPITAL.—Consulting Dentist: must be registered Licentiate in Dental Surgery. Applications to the Secretary ten days before the election on November 5th.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—Assistant Surgeon. Applications to the Secretary by October 25th.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck Street, Cavendish Square.—Assistant Resident Medical Officer: doubly qualified. Appointment for six months. Salary at the rate of £80 per annum, with furnished apartments, attendance, coal, and light. Applications to the Directors by October 31st.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, AND MEDICAL MISSION DISPENSARY FOR THE POOR, Plaistow, E.—Resident Medical Officer: double qualifications: under 40. Applications to Rev. T. Given-Wilson, M.A., Vicar of Plaistow, E.

ST. PANCRAS AND NORTHERN DISPENSARY, 128, Euston Road, N.W.—Honorary Surgeon. Applications to H. Peter Bodkin, Hon. Sec., 38, Gordon Street, Gordon Square, W.C., by November 2nd.

STOCKTON AND THORNABY HOSPITAL, Stockton-on-Tees.—House-Surgeon (non-resident): doubly qualified. Must reside near the hospital, and devote the whole of his time to the institution. Salary, £250 per annum. Applications and testimonials to H. G. Sanderson, Secretary, by November 5th.

SUNDERLAND INFIRMARY.—House-Physician. Salary, £250, rising £10 annually to £260 with board and residence. Applications to the Chairman of the Medical Board by November 7th.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House-Surgeon: doubly qualified. Salary, £150 per annum, and £20 per annum for dispensing, with furnished apartments and attendance. Applications and testimonials to Tyson Kitchen, Secretary, by November 15th.

MEDICAL APPOINTMENTS.

BENNETT, Hughes, M.D. Edin., F.R.C.P. Lond., appointed Consulting Physician to the Hospital for Epilepsy and Paralysis, Regent's Park.

BOTTOMLEY, B.A., M.B., B.C. Cantab., appointed Senior Resident Medical Officer to the Royal Free Hospital, *vice* W. A. Bowring.

GRAVE, J. A., M.B., B.Ch. R.U.I., appointed Second House-Surgeon to the Royal Southern Hospital, Liverpool.

EMSON, A., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer for the Workhouse and Dorchester District of the Dorchester Union, *vice* G. A. George, L.R.C.P. Lond., M.R.C.S. Eng., resigned.

EYALL, Mr. E. P., appointed Medical Officer for the Waterbeach District of the Cambridgeshire Union.

GUTHRIE, Leonard, M.A., M.B. Oxon., appointed to the charge of In-Patients, in addition to that of Out-Patients, at the Hospital for Epilepsy and Paralysis, Regent's Park.

HARRISON, Dr. G., appointed Medical Officer of the Workhouse and the First District of the Church Stratton Union, *vice* A. J. Fleming, M.D.C.I., M.Ch., L.R.C.S.

KIDD, Dr., appointed Resident Medical Officer of the Dundee Hospital for the Sick Poor, *vice* Dr. Croft.

LAMPLUGH, C., M.R.C.S., L.R.C.P. Lond., appointed Resident Clinical Assistant to the St. Marylebone Infirmary, Notting Hill, *vice* L. N. Gibbs, resigned.

LINDSAY, D., Lander, L.R.G.P. and S. Edin., L.F.P.S. Glasg., appointed House-Physician to the Glasgow Royal Infirmary.

MARTIN, Richard S., L.R.C.P., L.R.C.S. Edin., L.F.P. and S. and L.M. Glasg., appointed Medical Officer and Public Vaccinator for the Lever District of the Bolton Union, *vice* Dr. Johnson Martin, deceased.

POOLE, S. M. B., C.M. Edin., appointed Medical Officer for the Second Wolverhampton District of the Wolverhampton Union, *vice* A. Freeman, L.R.C.P. Edin., L.M., M.R.C.S. E.

POWERS, G. H., L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Officer for the Gosforth District of the Whitehaven Union.

PROUDFOOT, Frank G., M.A. and M.B., C.M. Edin., appointed House-Surgeon in the Radcliffe Infirmary, Oxford.

ROBEY, W. Barrett, M.D., M.S., appointed Consulting Physician to the Bristol Hospital for Sick Children and Women.

STARKE, William H., M.B., C.M. Edin., appointed House-Surgeon to the Lancaster Infirmary.

THOMAS, T. W., M.R.C.S. Eng., L.S.A., appointed Medical Officer for the Caerphilly District of the Pontypridd Union, *vice* J. Llewellyn, deceased.

THOMSON, J. R., M.B., B.Ch. R.U.I., appointed Third House-Surgeon to the Royal Southern Hospital, Liverpool.

WATT, J. L., M.A. Aberd., M.B. C.M., appointed Medical Officer for the Second Division of the Third District of the St. Germain Union, *vice* A. B. Cheres, M.D. Aberd., L.R.C.S. Edin., resigned.

DIARY FOR NEXT WEEK.

TUESDAY.

LONDON POST-GRADUATE COURSE. London Throat Hospital, Great Portland Street, 5 P.M.—Mr. G. G. Wilkin: Acute Polyp.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. C. H. Keating: Cases of Intestinal Resection and Intestinal Faecoma. Mr. H. Allingham: A Series of Cases of Intestinal Resection.

TUESDAY.

LONDON POST-GRADUATE COURSE. Bethlem Royal Hospital, 2 P.M.—Dr. Percy Smith: Developmental Insanity, Circular Insanity.

THE CLINICAL MUSEUM, 21, Great Portland Street.—Open at 3 P.M. Lecture at 4.

WEDNESDAY.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. J. K. Fowler: On Bronchitis.

NORTH-WEST LONDON CLINICAL SOCIETY, North-West London Hospital, Kentish Town Road, 8.30 P.M.—Presidential Address by Sir Richard Quain, Bart., F.R.S., on Some General Remarks on Professional Topics.

WEST LONDON HOSPITAL, Hammersmith, W., 5 P.M.—Dr. Hall: Throat Cases (Post-graduate course).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Gowers.

THURSDAY.

LONDON POST-GRADUATE COURSE. Hospital for the Paralysed and Epileptic, Queen Square, 2 P.M.—Dr. Beever: Muscular Atrophy. Hospital for Sick Children, Great Ormond Street, 3.30 P.M.—Mr. W. A. Lane: Selected Surgical Cases. Central London Sick Asylum, Cleveland Street, 5.30 P.M.—Dr. T. Henry Green: Cases in the Wards.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Dr. Goodhart will open a discussion on Spasmodic Asthma and its Treatment.

FRIDAY.

LONDON POST-GRADUATE COURSE, Bacteriological Laboratory, King's College, 3 to 5 P.M.—Professor Crookshank: Lecture: Tuberculosis and Leprosy. Practical Work: Staining Sputum and Sections.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, W., 8.30 P.M.—A Discussion on Gastric Ulcer will be opened by Dr. Bond and Mr. Bruce Clarke. Drs. Alderson, Drowitt, Campbell Pope, S. Taylor, and Mr. Keating will take part in the discussion.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, 8.15 P.M.—Mr. Mayo Collier: Chronic Nasal Obstruction.

SATURDAY.

LONDON POST-GRADUATE COURSE. Bethlem Royal Hospital, 11 A.M.—Dr. Percy Smith: Climacteric and Senile Insanity.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

EDWARDS.—On the 17th inst., at Banbury, Oxon., the wife of Henry J. Edwards, L.R.C.P. and S. Edin., of a son.

NORTH.—On October 18th, at Westfield House, Stapleton Brampton, Cumberland, the wife of Thomas North, B.A., M.B., of a daughter.

SCOTT.—On October 12th, at 10, St. George's Terrace, Sheffield, the wife of George H. Scott, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

FRANEY—LANDDOWN.—October 16th, at St. Paul's Church, Clapham, Arthur Britton Franey, L.R.C.S., L.R.C.P., of Hadleigh, Suffolk, only son of Edward Franey, M.R.C.S., L.S.A., Banbury, Oxon., to Amy Estelle, daughter of the late T. W. Landown, J.P., of Plymouth, and Mrs. Landown, 60, Brownfields Road, Clapham, London.

STEEGMANN—BARNETT.—On October 15th, at St. George's Church, Barrow-in-Furness, by the Ven. Archdeacon Phillips, Edward J. Steegmann, M.B., of Grove Park, Chiswick, to Mabel, daughter of Rear-Admiral Barnett, of Barrow.

DEATH.

BETTS.—September 4th, aged 28, at Antofagasta, Chile, of pneumonia, Frederick Bernard Betts, M.R.C.S. Eng., L.R.C.P. Lond., eldest son of J. F. H. and Catherine J. Betts, of 33, The Chase, Camm Common.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 55, Strand, W.C., London; those concerning business matters, such as delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 55, Strand, W.C., London.

A FURTHER desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 55, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should enclose them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT BE RETURNED UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PHYSIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be printed under their respective headings.

QUERIES.

X. Z. asks for information as to climate of Devonshire, whether bracing or otherwise, especially in the neighbourhood of Okehampton.

H. A. C. would be glad if any member would inform him what treatises have been written on the subject of aphasia, and where they might be obtained.

STROPHANTHUS.

DR. E. D. SHIRLEY (Holloway, Maresfield) asks for information as to the physiological action, subsidiary effects, and therapeutic uses of strophanthus, and as to the indications for strophanthus in disease as distinguished from the indications for digitalis.

HYPODERMIC MEDICATION.

MR. JOHN HODDY (Manchester) asks for opinions on the efficacy of those pellets which dissolve in the barrel of the hypodermic syringe. It has been stated that these pellets are useless, "since the active substance supposed to be used will not by itself dissolve without trituration."

CYCLING FOR WOMEN.

W. H. asks for opinions on the effect of cycling on child-bearing. The idea he says is becoming popular that in a great measure it produces sterility in women, and that in the event of pregnancy the labour is rendered very difficult and dangerous. I have given my opinion against the theory that cycling tends to produce sterility, and also that I believe the theories opposing the passage of the child in labour are unduly strengthened, then from the same cause those of expulsion would also be correspondingly strengthened, and in consequence the state of affairs remains unaltered.

THE L. A. H. DUBLIN.

N. M. requires whether a L. A. H. Dublin, registered 1883, has power to recover in a Court for medical attendance; also what is the single qualification possessed by the holder of such diploma.

"A Licentiate of the Apothecaries' Hall, Dublin (1888) has power to recover fees in a Court of law for medical attendance. The "single" qualification he possesses is the right to practise medicine, as distinguished from the right to practise both medicine and surgery, which is sometimes referred to as a double qualification.

ANSWERS.

THE INFORMATION supplied does not warrant us in expressing any opinion.

M. J. W.—We are informed that the trusses referred to are looked upon as out of date. We have been unable to ascertain the address of the maker.

MALTA.—The English translation of *M. Pasteur, Histoire d'un Savant par un Français*, published under the title *Louis Pasteur, his Life and Labours*, by George Thompson, Green, and Co., Ltd., the original French work was written by Pasteur's son-in-law M. Vallery-Radot. The English translation by Lady Claude Hamilton is prefaced an interesting introduction by the late Professor Tyndall.

ATTEMPTED GUNSHOT SUICIDE.

A CORRESPONDENT is thanked for interesting details of this painful case, but it is undesirable any opinion should be here expressed as to the treatment adopted.

THE EXAMINATION FOR F.R.C.S. EDIN.

TORY.—In reply to a circular inquiry, it was stated in the BRITISH MEDICAL JOURNAL of April 7th, 1895, that no books are generally recommended to be read for the Fellowship examination of the Royal College of Surgeons of Edinburgh, and that it would suffice to read any of the standard textbooks, such as those of Erichsen, Treves or Holmes. As to genito-urinary surgery, our Edinburgh Correspondent stated in the JOURNAL of May 4th, 1895, p. 1188, that the articles on genito-urinary surgery in the works of Holmes or Harrison, with the addition of the chapters in Treves's *Manual of operative surgery* will be sufficient for the examination so far as reading is concerned. A good work on abdominal surgery is Mr. Greig Smith's volume with that title.

AMBULANCE LECTURE.

IN reply to an inquiry by "I. G. S." in the BRITISH MEDICAL JOURNAL of October 19th, the Secretary of the National Health Society begs to call attention to their first aid textbook, entitled, *Aids to the Injured and Sick*, by H. W. Gell, M.A., M.R.O.S., M.R.C.S., priced 1s. or bound in cloth, 6s. The Secretary also directs the attention of "I. G. S." to *The Human Body*, by Owen Lukester, M.R.C.S., which contains a coloured mannikin, showing the position and relative size of the various organs of the human body, arranged in a movable form. The Society has also in its possession a large collection of anatomical and other diagrams to the use of which members of the Society are entitled. Membership is constituted by the payment of one guinea annually. A list of the Society's publications and all further particulars can be obtained on application to the Secretary, 55, Berners Street, W.

OVERLAPPING OF THE TOES.

MR. T. S. ELLIS (Gloucester) writes: I would point out to "A Member" my reasons for believing that a foot such as he describes must be functionally defective, but that the condition does not require operative treatment. If the second toe be raised above the level of the others it will, when packed in a middle-pointed boot or sock, interfere with that free movement of the great toe necessary for effective propulsion. This latter in rest is inclined upwards and outwards, somewhat over the next (as indicated in the frontispiece of *The Human Foot*), and in action moves downwards and inwards away from the others.

I suggest as a remedy for the case in question this exercise, to be done with bare feet. Let him stand with hands on hips and throw the body backward till it is in danger of falling, then spring forward, gripping the ground with the toes, as he must do in order to form fixed points from which the extensors can act in drawing the body forwards. Every toe will soon find the ground level. Let him wear boots with plenty of room on the inner side and socks with a special stall for the great toe. He should acquire a habit of pressing the toes against the ground as he walks, and should not turn them outwards in the conventional manner.

"LENNOX."

L. W.—It would appear that this person, since he does not assume any medical or surgical titles, does not come within the scope of the Medical Acts, and cannot be dealt with under the Apothecaries Acts. A case like this shows how imperative it is to amend the Medical Acts, so as to make "practising for gain" a penal offence by unqualified and unregistered persons. Any person who has been treated by "Lennox" being led to believe that he was a duly qualified medical practitioner, and who has paid for such treatment, could of course bring an action against him for obtaining money under false pretences. The newspaper which permits "Lennox" to prescribe for correspondents in its columns is rapidly becoming the organ of the unqualified, and its pages are full of abuse of all regular practice. This is matter for regret, as its proprietor is well known for his munificent donations to cottage hospitals and convalescent homes, a strange contrast and one difficult to comprehend.

CIVILIAN PRACTITIONERS IN MEDICAL CHARGE OF TROOPS.

H. G. D.—Unless there is a definite arrangement to the contrary, it is, we believe, understood that civilian practitioners undertake these military medical duties at contract rates. Supposing, however, that Army Form O 1887 is used as the form on which to base the account, there is nothing in it entitling the claimant to charge for camp inspection. Further, there is a note that for special cases remuneration will be allowed according to the circumstances and nature of the case, and surgical appliances (pilots) will be paid for according to circumstances. Another paragraph says that no collective charge as to surgical appliances or attendance will be allowed on any proceeding whatever, so that the charge for the camp inspection is not to be added to the rest, but there is nothing in this form which entitles the claimant to charge for examining men for foreign service.

The regulations under which civilian practitioners are employed are clearly set forth in pp. 27, 28, 29, *Army Medical Regulations*. Briefly they may be summed up as follows. That principal medical officers will make arrangements and submit them to commanding officers, who will cause the arrangements made and the remuneration sanctioned to be promulgated in Army Orders. Civilian practitioners may be employed under the terms specified in the Royal Warrant relating to pay without reference to any higher authority, but no exceptional rate will be adopted without the recommendation of the Director-General and the sanction of the Secretary of State. Should a body of troops be lost without medical aid the commanding officer is instructed at once to report it to the principal medical officer. In the meantime making arrangements to meet the emergency, the terms to be at once reported to the Director-General. Under any circumstances no claim will be entertained unless made to conformity with the rates laid down in the Royal Warrant relating to pay, etc., and unless it is submitted by the commanding officer through the principal medical officer to the Director-General on Form O 1887, which under some very exceptional circumstances, in which case full explanations are required, and Form O 1887 accurately filled in. The form also must be signed by the commanding officer, the principal medical officer of the district, and the Director-General.

NOTES, LETTERS, Etc.

THE REESE FUND.

MR. THOMAS WATKINS (Castle Bunka, Ystradgynlais, near Swansea) Honorary Secretary of this fund, desires to acknowledge the receipt of a subscription of £1 from A. B. The late Dr. Reese, of Ystradgynlais, was killed by lightning while on his way to a patient, leaving his widow and eleven children, of whom four are quite young, unprotected. At a public meeting held on August 7th, a committee was formed to raise a fund to place a memorial stone over Dr. Reese's grave, and to present a testimonial in money to his widow. The treasurer of the fund is the Rev. E. L. D. Glasley, Rector of Ystradgynlais. We are informed that it has been decided to close the fund on November 2nd, and that further contributions are greatly needed.

"A REAL MEDICAL TRIUMPH"

We have received a very long letter from Dr. Heryng, of Warsaw, relative to a paragraph which appeared under the above heading in the BRITISH MEDICAL JOURNAL of August 17th. In that paragraph certain statements made in an article published in the *Pall Mall Gazette* of August 13th as to the results of the treatment of laryngeal tuberculosis by *condensation* were criticised as being likely to excite false hopes in sufferers from that affection. Dr. Heryng says the article referred to appeared without his consent, and we of course accept his statement on that point. The fact remains, however, that he is somewhat unfortunate in the possession of indiscreet friends who sing his praises in the lay press. We do not wish to be understood as suggesting that Dr. Heryng himself is to be held responsible for these newspaper puff, but we must be allowed to express the opinion that they are deplorable. By far the greater part of Dr. Heryng's letter is taken up with an elaborate vindication of his scientific position on the question of the treatment of laryngeal tuberculosis, which has never been impugned by us; on the contrary, as he himself acknowledges in his letter, we fully admitted the services which he has rendered to medicine in this matter. His views on the subject, as we gather from his letter and from his writings on the subject, are in substantial agreement with those expressed in our article; it therefore appears unnecessary to reproduce them here. In short our strictures were not directed against Dr. Heryng, but against a lay newspaper which had published an article highly laudatory of the treatment of a painful and deadly disease which we considered likely to mislead a class of sufferers peculiarly liable to be misled by delusive hopes of cure.

AGAINST THE PIPE.

In the monthly letter of the Committee of the English Anti-Tobacco Society to members and friends, there occurs the following passage: "The smoking nuisance (through the addition of myriads of uricines, ragged and otherwise, to the smoking army) is extending at such a rate that unless those who are daily nauseated by it make an immediate and resolute stand for their rights they will soon be left without any hope of escape from a pest which robs them of so much of the physical enjoyment of life."

The health authorities are, the Committee thinks, "by the provisions of the Health Act empowered to suppress nuisances of all kinds in their respective districts on complaint being duly lodged and proof forthcoming, and we have little doubt that if the subscriptions were raised to adequately support a test case, a decision would be given which would demonstrate public smoking to be an illegal, unjust, ungentlemanly, and therefore an unchristian habit."

FORMS FOR "BIRTH AND DEATH RETURNS."

A SPECIMEN copy of a form designed by Dr. Vincent for use in connection with returns furnished by subdistrict registrars to medical officers of health has been received from the publisher, F. W. Count, East Dereham, Norfolk. The form appears well adapted for the purpose for which it is designed; it is claimed that it possesses the advantages of allowing adequate space for necessary details, and of saving time in filling up by the use of abbreviations. The price of the form is 4s. for 50 and 7s. 6d. for 100.

THE PUBLIC AND MEDICAL ETIQUETTE.

F. writes: The following letter received from a lady is interesting as an example of ideas of medical etiquette among the public: "Dear Dr. —, My maid's sister is lying very ill of typhoid fever at 56, rue —, and I do not feel quite satisfied that she is being treated according to modern principles. I should be immensely obliged if you would look in at her as soon as you can, and see what you think of the case and the doctor's prescriptions."

LETTERS, COMMUNICATIONS, Etc., have been received from:

(A) Acetone; Mr. J. Abbott, Tunbridge Wells; Dr. J. Adam, Dingwall; Dr. H. E. Armstrong, Newcastle-on-Tyne; Dr. J. Abcarius, Beyroul. (B) Messrs. F. Bayer and Co., Elberfeld; Mr. G. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

REMARKS ON THE NAUHEIM (SCHOTT) TREATMENT OF HEART DISEASE.

*Read at the Meeting of the Birmingham and Midland
Counties Branch, October 10th, 1895.*

By ROBERT SAUNDAY, M.D., F.R.O.P.,

Professor of Medicine in Mason College; Physician to the General
Hospital, Birmingham.

GENTLEMEN.—When I put down my name to read a paper upon this subject, I intended it to be the result of several months' clinical experience; but, having accepted the invitation of your secretaries to read it at this meeting, I have been obliged to content myself with something less, and I must ask you to excuse me if I am able to do little more than summarise information already published.

Nauheim is a small town in the Grand Duchy of Hesse, about forty minutes' journey by rail, due north, from Frankfurt, and only a pleasant day's excursion by carriage from Homburg, where I was staying for a few days last August. When I visited Nauheim Dr. Schott received me in the kindest manner. He began by taking me to see an American doctor who was undergoing the treatment, and who was very much interested in the system and familiar with its details. He showed me notes of a number of cases which had been under Dr. Schott's care, and after looking over them we walked to Dr. Schott's house, where we were joined by Dr. Bezly Thorne.

Dr. Schott introduced a German doctor who was also under treatment, and who kindly allowed me to examine him. His heart was greatly dilated; to the left 1½ inch beyond the vertical nipple line, to the right 1 inch beyond the right edge of the sternum, above to the upper border of the left third costal cartilage. There was no murmur except a slight systolic blowing in the pulmonary area. His pulse was 110, of low tension, and unequal in force and volume. Dr. Thorne made him go through the first and second exercises (see below) which took three or four minutes, and I was then asked to percuss his heart again. I may mention that I had been unable to localise the apex beat. On this second percussion I was startled to find that the area of dulness had increased by about an inch in every direction. The pulse was 112, but I could not recognise by the touch any alteration in its character. As I was unwilling to admit that the heart had actually increased to such an extent so quickly and after two such very simple movements, I suggested that perhaps the lungs had expanded so as to overlap the heart. Dr. Schott said they were quite used to that objection; but had I been able to localise the apex beat I could not have doubted if that had receded, which he assured me it did. Moreover, he added, if I had percussed out the lower dulness I should have found that the upper margin remained unaltered instead of receding downwards, as it should do if the lungs were more fully expanded.

After this we went to see the baths, first climbing up to the two towers in which the brine is stored and its carbonic acid allowed to escape. The water, which flows up in two great white foaming fountains, becomes on ascending quite yellow from the precipitation of iron previously held in solution by the gas. This gas-free water is used for the earlier baths, but later on in the course the water is drawn by another set of pipes direct from the spring, and is highly charged with CO₂, and in the strongest bath of all, the so-called "Sorrento," the foaming water is allowed to flow in and out of the bath in a continuous stream, while the patient lies in a good imitation of a strong surf.

I did not have an opportunity of seeing a patient in the bath, but Sir T. Graham Brown and Dr. Hoffman (who were staying at Homburg) told me they saw and examined a man whose heart was greatly dilated and his pulse 114, irregular, small and irritable. After a few minutes' treatment in the bath (reservoir water) the pulse had fallen to 114, and in six

minutes to 103, whilst it had become evidently better filled. After eight minutes they percussed his heart, and found that the dulness had receded an inch in every direction. Unfortunately they omitted, as I did, to take the level of liver dulness, but I shall refer to this later on, and will show that there is no reason to doubt the correctness of these observations.

HISTORY.

The beneficial effects of Nauheim baths in the treatment of chronic cardiac disease were first proclaimed by the late Professor Beneke, about 1872, before which time there existed an unbounded dread of emptying them in these cases. A few years afterwards his teaching was reinforced by monographs from the pens of Drs. August and Theodor Schott, and the Nauheim bath treatment for heart disease gained considerable repute in Germany. The success obtained by the Zander movement cure induced Dr. A. Schott to devise a system of mild gymnastics or drill for the treatment of neurotic and hysterical patients, of whom a considerable number come annually to Nauheim. Some of these patients had rapid weak hearts, and it was discovered with some surprise, that the exercises, instead of quickening the heart's action, slowed and steadied it; further experience showed them that this result followed also in organic disease of the heart, so that a method originally devised for steadying and strengthening the nervous system proved to be a valuable adjunct to the bath treatment of cardiac disease. This little history was told me by Dr. Schott himself, and noted down at the time. The method thus evolved was put into practice and described in the medical press without attracting much attention. Undoubtedly our present knowledge of the subject is due almost entirely to the enthusiastic work of Dr. Bezly Thorne, who was first led to its study by observing that cases of cardiac disease which had been sent to Nauheim for rheumatic or gouty complications returned so much improved that he was impressed with the importance of the new system, and made himself thoroughly acquainted with its details by repeated visits to Dr. Schott.

The more he saw of the method and the more he learnt of its results the more convinced he became that a real discovery had been made of the greatest utility, and one which was capable of general application. In May of last year he published an account of it in the *Lancet*, which was in the main a reproduction of an article Dr. Schott had contributed to the same journal three years previously, but he was more successful in arousing attention, and from that time the profession has gradually evolved more and more interest in the work, a large number of English patients have been sent to Nauheim, and articles on the subject have been published by Sir P. Smyly, Dr. Wethered, Dr. J. J. Croft, Dr. Sir William Broadbent, Dr. Allen Sturges, and Mr. Armstrong. In all these the method is spoken of with favour, and some important results are given.

Dr. Bezly Thorne has increased our debt of obligation to him by publishing an admirable handbook, which explains the system very clearly, and by means of excellent illustrations enables anyone to learn the exercises.

The employment of regulated muscular exercise in the treatment of heart disease has been also suggested by Dr. Lauder Brunton, Dr. Symonds Keele, and Dr. Henry Campbell, although the two last do not mention the Nauheim method.

THE BATHS.

The medicinal waters of Nauheim are derived from twelve springs, of which four are used for drinking and three for the baths. The bath waters contain from 2 to 3 per cent of sodium chloride, 2 to 3 per 1000 of calcium chloride, some carbonate of iron, and a very large amount of carbonic acid gas. The waters used for drinking contain the same mineral salts, but in varying proportion, the Kurr and Kurrbrunn waters being chiefly sodium, while the Luthersbrunn is chiefly calcium, and the Schwabensbrunn rich in iron.

The baths are given at a temperature of from 32° to 37° F., and their duration is from six to eight minutes. The course begins with a 1 per cent salt bath, and, as time goes on, the amount of solids may be gradually increased, the temperature lowered to 34°, and the time of immersion increased to twenty or thirty minutes, but throughout the course must be interrupted by frequent intervals of exercise.

Later on the baths contain the water charged with carbonic acid gas, and finally, in suitable cases, the "Strombad," with its continuous rush of foaming water is permitted. After each bath the patient should rest an hour. The lowest temperature and maximum duration mentioned above must be approached very cautiously, and should not be employed in grave cases. The immediate effects of the bath are to reduce the rate of the pulse and to increase its force and tension; at the same time the area of cardiac dulness retracts in all directions. After the baths these effects gradually disappear, but it is claimed that at the end of the course, which should last at least six weeks, and often may be prolonged with advantage, permanent improvement is effected. It is also maintained that early rheumatic valvular affections are cured, murmurs disappear, and myocarditis is arrested.

It is well known that a bath of lower temperature than the body causes more or less contraction of the vessels of the skin, while a bath which is hotter dilates them; moreover, the gaseous or saline contents do not stimulate to greater vascular contraction; on the contrary, they favour dilatation. All authorities are agreed that a cool bath eventually lowers the number of heart beats, though some have observed an initial rise, possibly due to psychical influences, while in baths hotter than the body or of the same temperature the frequency of the pulse is increased. The question is whether this reduction of the number of the heart beats is merely the result of the operation of Marey's law—contraction of the vessels of the skin increasing the blood pressure and thereby slowing the heart—or whether it is the consequence of a reflex inhibitory influence, as Dr. Schott believes.

Leichtenstern, although writing with some scorn of those "who (pleading like Cicero *pro domo*) contend that lukewarm or cold baths, and especially salt baths rich in carbonic acid, are a tonic of the first rank for a weakened heart," says that if the effect is produced by the vascular contraction of the skin stimulating the left ventricle, such baths are not without danger, but "it is different if the cool simple or salt bath is to act as a regulator of the heart's activity, the possibility of which has not yet been shown by any proof. If it were in that way possible to bring a heart which was arrhythmic and wearing itself out in unusually frequent and fruitless contractions to a more regular and slower action, in that case the systole would be prolonged and more yielding, the emptying of the ventricle would be completed, the diastolic pause lengthened, and along with that the removal of the fatigue products favoured and the nutritive condition of the heart's muscles improved." This is the *modus operandi* of the baths according to Dr. Schott, but it has certainly not been demonstrated.

The following diagrams and pulse tracings, taken from cases treated during the last few weeks in the wards of the General Hospital, support the general proposition, namely, that the baths diminish the area of dulness, while increasing the force and tension and diminishing the frequency of the pulse. (See Figs. 1, 2, 3, 4, 5, 6, and 7.)

I have been much impressed by the testimony of my friend, Dr. Allen Sturge, of Nice. He went to Nauheim in June, 1894, to try to get cured of an irritable heart, the consequence of an attack of influenza in the previous February. At the commencement of treatment his pulse was 100, and his heart's apex was 2 cm. external to the vertical nipple line. After five weeks' treatment by baths and massage only, without exercises, his pulse had fallen to 64, the heart's apex receded to 1 cm. inside the nipple line, and he was completely restored to health. In his case, Dr. Sturge explains, the exercises seemed to make his heart more irritable.

In the opinion of Dr. Schott and of Dr. Bazly Thorne these baths may be chemically prepared, and Mr. Armstrong, of Buxton, has given the following formulæ for a series of such artificial baths, in which the quantities are calculated for 40 gallons of water:

Bath No. 1. Sod. chlorid., 4 lbs.; calc. chlorid., 6 ozs.

Bath No. 2. Sod. chlorid., 5 lbs.; calc. chlorid., 8 ozs.

Bath No. 3. Sod. chlorid., 6 lbs.; calc. chlorid., 10 ozs.; sod. bicarb., 6 ozs.; acid. hydrochlor., 7 ozs.¹

Bath No. 4. Sod. chlorid., 7 lbs.; calc. chlorid., 10 ozs.; sod. bicarb., 8 ozs.; acid. hydrochlor., 12 ozs.

Bath No. 5. Sod. chlorid., 9 lbs.; calc. chlorid., 11 ozs.; sod. bicarb., 1 lb.; acid. hydrochlor., 1½ lb.

Bath No. 6. Sod. chlorid., 11 lbs.; calc. chlorid., 12 ozs.; sod. bicarb., 1½ lb.; acid. hydrochlor., 2½ lbs.

I have been using only the first four of these baths, which are probably those most likely to be employed commonly, and find no difficulty in arranging them in our hospital bath room. A porcelain bath is of course likely to suffer less from the effects of the chemical constituents, but so far our metal baths do not show any indication of being injured.

THE EXERCISES.

The exercises are called by Dr. Schott "Widerstandsgymnastik," or resistance gymnastics, and consist in slow movements executed by the patient and resisted by the physician or operator. A short interval is allowed after each movement, during which the patient sits down. The exertion employed must be very small, and should cause no increase in respiratory movements, flushing, or pallor. The patient should be loosely and lightly clothed, and instructed to breathe quietly. The resistance made should be of such a kind that the patient may always feel himself easily the master. The operator must not grasp or in any way constrict the limb, but should oppose by the hand held flatly. The movements are nineteen in number:

1. Arms extended in front of body on a level with shoulder, hands meeting; arms carried out until in line, and brought back to original position.

2. Arms hanging at sides, palms forwards; arm flexed at elbow until tips of fingers touch shoulder, back to original position; one arm only moved at a time.

3. Arms down, palms forward, arms carried outwards and upwards until thumbs meet over head; back to original position.

4. Hands in front of abdomen, fingers flexed so that second phalanges touch those of opposite hand; arms raised until hands rest on top of head; back to original position.

5. Arms down, palms against thighs, arms raised in parallel planes as high as possible; back to original position.

6. Trunk flexed on hips; return to original position.

7. Trunk rotated to left, to right; return to original position.

8. Trunk flexed laterally.

9. As No. 1, but fists clenched.

10. As No. 2, but fists clenched.

11. Arms down, palms against thighs, each in turn raised forwards and upwards until arm is alongside of ear, then turned outward, and arm descends backwards.

12. Arms down, palms to thighs, both together moved backwards in parallel planes as far as possible without bending the trunk forwards.

13. Thighs in turn flexed on trunk, opposite hand resting on chair.

14. Lower extremities in turn extended fully, and bent on trunk forwards and backwards to extreme limits of movement, opposite hand resting on chair.

15. Legs in turn flexed on thigh, both hands on chair.

16. Feet together, lower extremities in turn abducted as far as possible, and brought back to original position, opposite hand on chair.

17. The arms, extended horizontally outwards, are rotated from the shoulder-joint to the extreme limits forwards and backwards.

18. The hands in turn are extended and flexed on the forearm to extreme limits, and brought back in line with arm.

19. The feet in turn are flexed and extended to extreme limits, and then brought back to their natural position.

These exercises are easily learnt, and nurses make very good operators, as they do not resist too much. I found difficulty in making my resistance sufficiently weak, and I should be afraid that this would stand in the way of training male operators generally; at any rate they would need careful selection.

The effects of the exercises are the same as those of the baths—namely, the area of cardiac dulness is reduced, while the pulse becomes slower and stronger. It is very difficult to get trustworthy sphygmographic evidence of the effects of the baths and exercises, as the adjustment of the instrument

¹ Dr. Thorne uses Sandow's effervescent tablets as more convenient and not destructive to baths, etc.

affects the result so greatly that two tracings taken at different times are only roughly comparable.

It is not to be expected, and certainly not to be desired, that the changes in the pulse should be very marked, and consequently the minute characters of the tracing become important. Dr. Stacey Wilson is familiar with his own pulse tracing, and kindly allowed some continuous sphygmograms to be taken before, during, and after a simple resisted movement. He has calculated the averages for the two experiments as follow:

Experiment I, October 5th:

	Amplitude	Tidal Wave.	Dicrotic Notch.	Dicrotic Wave.
Before movements	13.0	5.0
During ..	14.4	3.4	5.4
After ..	15.4	5.6	4.0	5.7

Experiment II, October 7th:

	Amplitude	Tidal Wave.	Dicrotic Notch.	Dicrotic Wave.
Before movements	17.0	5.5	7.0
During ..	17.7	6.2	8.0
After ..	17.3	8.75	5.5	7.6

These figures show that the amplitude of the pulse and its tension and force, so far as these are indicated by the sphygmograph, were all increased during the movements, and immediately afterwards.

I also show you pulse tracings and diagrams of the heart's dulness taken from patients before and after the exercises, and you see that the effect is in the mean the same as that of the bath, namely, the cardiac area of dulness is diminished, while the force and tension of the pulse are increased. (See Figs. 8, 9, 10, 11, 12, 13, and 14.)

I have carried out the treatment by baths and exercises for the last three or four weeks on several patients in the General Hospital.

CASE I.—The first is a case of Graves's disease associated with glycosuria. His pulse is always rapid, and often very irregular. The exercises were begun on September 9th, but were stopped on October 2nd, as his pulse was very seldom slowed after them, and its general condition was not at all improved. He has had baths up to No. 4, and these up to the present have had no permanent effect on his pulse. This shows the immediate effect of a bath on his pulse rate:

Before bath 105 per minute.

1st minute	103
2nd ..	103
3rd ..	103
4th ..	100
5th ..	104
6th ..	106
7th ..	104
8th ..	103

Ten minutes after 106 per minute.

The pulse was irregular at first, but became quite regular and of much higher tension. We shall continue the baths for a time, as he likes them, but their effect on the progress of the disease is doubtful.

CASE II is a boy with a dilated heart and mitral disease. In the course of treatment he developed symptoms suggestive of slight pericarditis, for which the baths and exercises had to be omitted for some days. Hence the case has not been a very fair one. The bath and movements have generally slowed his pulse, and in the bath there was considerable reduction of the area of cardiac dulness in all diameters (see Figs. 4, 5, 6, and 9).

CASE III was also a boy with valvular disease and a dilated heart. His temperature was not very steady on admission, and became so irregular that the treatment was stopped and will only be resumed when he improves.

CASE IV is a boy with mitral disease and a dilated heart. He has only been under treatment about a fortnight, so that it is too soon to speak of results, but he is going on well (see Figs. 7, 10, 11, and 12).

CASE V is another boy with mitral disease and a dilated heart under the care of Dr. Wilson. He is a very suitable case, as he has no recent acute trouble of any kind, while the other three have each had recently more or less rheumatism. The movements and bath slow his pulse, and in the bath the heart's area and position altered as shown in the diagram. As can be seen the area contracted very much, but the apex tilted up and beat outside the nipple line in the fourth interspace. Was this due to rotation of the heart or to contraction of the right side, so as to bring up to the front the left ven-

tricle, which had been previously pushed away from the wall of the chest? The boy has improved, as Dr. Wilson will tell you (see Figs. 1, 2, 3, 8, 13, and 14).

CASES FOR WHICH THE SYSTEM IS SUITABLE.

The system is claimed by Dr. Schott to be of special value in all cases of chronic heart disease except where there is advanced degeneration of the myocardium, or aneurysm of the heart or great vessels, or advanced arteriosclerosis. It has proved of great service in all forms of valvular disease, in congenital cardiac defects, in simple dilated hearts without valvular disease, in the functional cardiac debility of anaemia, however induced, in nervous irritable hearts, in simple tachycardia, and in the rapid heart of Graves's disease. Dr. Thorne is led, partly by theoretical considerations, partly, no doubt, by experience, to speak hopefully of its prospects in the early stages of arterio-sclerosis and aneurysm, but I shall have occasion to show that his theoretical grounds are not altogether indisputable; and although the method, if cautiously employed, may do no harm, and may even strengthen the heart, it is not likely to do any good to these conditions and may prove disastrous. Therefore I think it wiser to advise that Dr. Schott's limitations should be regarded as the rule in practice.

RATIONALE OF THE SYSTEM.

The theory adopted by Dr. Schott, and which he stoutly maintained in Dr. Bezly Thorne's presence, is that the baths and the exercises act upon the heart through the nervous system by evoking a reflex influence which stimulates the action of the cardio-inhibitory or regulator nerves, thus slowing and strengthening the pulse; and though some of his friends in England take a different view he told me he adheres to this explanation. Dr. Bezly Thorne, on the other hand, believes the baths and exercises alike favour the circulation by dilating first the muscular arteries and afterwards those of the skin and thus relieve the heart from backward pressure. This view is supported by Sir William Broadbent and by his son, Dr. John Broadbent. The theory of Dr. Thorne is not consistent with the pulse tracings and manometric observations of Dr. Schott, nor with the physiological law that the heart beats vary inversely with the blood pressure.

If the effect of the baths and exercise be to diminish the blood pressure, the heart's action—following Marey's law—should be quickened; but all are agreed that the pulse is slowed. Sir William Broadbent recognises this difficulty, and endeavours to avoid it by retaining Dr. Schott's hypothesis of a reflex nervous effect on the heart as a second string to his bow. He says: "It is not by any means denied that this (that is, reflex nervous influence) plays some part in the process, more particularly as diminished peripheral resistance has been shown experimentally to accelerate the action of the heart, whereas it is here accompanied by diminished frequency of the pulse. My observations, however, have led me to the conclusion that the primary and principal effect is on the peripheral circulation." It seems to me that before coming to this conclusion Sir William Broadbent could hardly have had his attention directed to the pulse tracings and measurements of pulse pressure published by Dr. Schott and republished by Dr. Bezly Thorne, or he must have overlooked them. So far as my tracings go they agree with Dr. Schott's, and at least some opposing evidence of the same kind should be advanced by those who differ from him.

Dr. Thorne supports his theory by quoting from Dr. Lauder Brunton's Harveian oration of last year. In that address Dr. Brunton drew attention to some experiments of Ludwig, which show that when under the influence of stimulation of the vasomotor centre, the arterioles of the skin and intestine contract, the blood accumulates in the muscles, and the tendency of the blood pressure to rise is partly unavailing. But this certainly does not justify the conclusion that no rise takes place, which would be opposed to very common experience. Further, Dr. Brunton endeavours to show that during muscular exercise a similar transfer of blood to the muscles takes place, and acts in the same way. But he does not show that such transfer has the effect of doing more than counteracting the tendency to raise the blood pressure. Indeed, in another place he says, "Muscular exercise, there-

Fig. 14.—Pulse tracing from the same patient immediately after the movements, showing a smaller pulse of higher tension (Case v).

fore, has a special tendency to raise the blood pressure in the arterial system, and consequently to increase the resistance which the left ventricle has to overcome." This tendency may be moderated by the means he has suggested, but is it not going too far to claim that the blood pressure is thereby actually lowered? If such a fall takes place, it should be assigned to diminution in the force of the heart from fatigue, such as of course may occur after over-exertion, but of that there is at present no question.

I think no one can deny that the tracings and measurements before us show that the effects of the baths and exercises are to slow the heart and raise the blood pressure. If that be so, no explanation can be accepted which is inconsistent with the evidence. But I must guard myself against being supposed to support Dr Schott's theory. I agree with Sir William Broadbent that the principal and primary effect of the baths and exercises is on the peripheral circulation, but that effect is to raise the blood pressure, and the heart becomes slower in accordance with Marey's law. The beneficial results of the Schott system depend, in my opinion, upon the very careful and easily regulated method by which the extra work is imposed upon the muscular wall of the heart, which is thereby developed and strengthened, as any other muscle is developed and strengthened, by systematic graduated exercises and not by any hypothetical reflex nervous effect upon the heart.

This view seems to be terribly alarming to some of the advocates of the Schott system, apparently because it suggests that the method might be dangerous under certain conditions. But if there is no danger, why does Dr. Schott object to its use in grave myocarditis, aneurysms, and advanced arterio-sclerosis? If it only regulates the heart's action it can do harm, but it does more than that: it raises the blood pressure, increases the tension of the walls of the heart and arteries, and where myocarditis is very advanced or the vessels are ready to give way from disease of their walls, it may produce disaster.

I see only good from the recognition of these limitations to the system, and I consider that a sound estimate of the mechanism involved will tend to prevent its indiscriminate use, while the success which has attended the practice of Dr. Schott and his followers assures us that, followed out on his lines and within the limits he has laid down, it possesses no dangers which should deter us from recommending its use to our patients in suitable cases.

MOUNTAIN CLIMBING.

It is the practice at Nauheim to supplement the cure by sending people to climb gradients at one of the higher health resorts in the Taunus, Black Forest, or Switzerland. This exercise, which is known to be not without danger, may be safe enough for hearts which have been already strengthened by the graduated Nauheim system; it was long ago advocated by Dr. Stokes, though it is generally associated with the name of its more recent advocate, Professor Oertel, of Munich.

Stokes, speaking of the treatment of fatty heart, says: "We must train the patient gradually but steadily to the giving up of all luxurious habits. He must adopt early hours, and pursue a system of graduated muscular exercise; and it will often happen that after perseverance in this system the patient will be enabled to take an amount of exercise with pleasure and advantage which at first was totally impossible, owing to the difficulty of breathing which followed exertion. This treatment of muscular exercise is obviously more proper in younger persons than in those advanced in life. The symptoms of debility of the heart are often removable by a regulated course of gymnastics, or by pedestrian exercises, even in mountainous countries such as Switzerland, or in the Highlands of Scotland or Ireland. We may often observe in such persons the occurrence of what is commonly known as 'getting the second wind,' that is to say, during the first period of the day the patient suffers from dyspnoea and palpitation to an extreme degree, but by persevering, without over-exertion, or after a short rest, he can finish his day's work, and even ascend high mountains with facility." He adds in a footnote that he has seen the most beneficial effects on the weakened hearts of young men "in persons who had spent the summer walking through the Alps,

when during exercise they were under constant perspiration." He concludes his remarks by urging caution in advanced life, where the disease of the heart is frequently complicated by atheroma of the aorta and affections of the liver and lungs.

Oertel, whose writings on the treatment of diseases of the circulation, evince great breadth of view and a desire to grasp the fundamental principles involved, believes that the damaged heart suffers most from the excess of fluids in the body, owing to diminution in the secretion of the kidneys and the sweat glands, and this source of oppression is increased when obesity is also present. His system, therefore, aims first at reducing the amount of fluid, then in regulating the amount when this diminution has been secured. To do this he seeks to increase the action of the skin, lungs, and kidneys, while limiting the amount of fluid ingested; but he admits that it is difficult by drugs to stimulate these organs efficiently, and he therefore recommends increased muscular activity by long walks, ascents—in short, by mountain climbing, which leads to increased water excretion from the skin and lungs. He also speaks well of Turkish baths, vapour baths, and hot packs. With these means he gives an albuminous diet (eggs), and restricts the amount of fluid taken to about half a litre (15 ounces) daily.

It is apparent that both Stokes and Oertel regard mountain climbing rather as a means of eliminating water than as directly aiding the heart, either by reflex inhibition, lowering vascular tension, or by exercising the heart, and so causing it, like any other muscle, to wax stronger by use. This last view certainly seems the most reasonable, and it is, as I understand, on this principle that Dr. Schott recommends it for suitable cases. He has quite abandoned Oertel's dietary, except where the heart condition is complicated by obesity, when he employs it in a modified form.

CONCLUSION.

A system like Dr. Schott's, which has been slowly evolved and perfected by years of careful clinical work, comes to us claiming attention chiefly from its practical results, and is, in my opinion, in no way discredited by any differences or doubts as to the proper theory upon which it is based. The latter only becomes important when new developments of the system are started, based on doubtful theories and lacking the support of his long experience.

I hope you will allow me to express my strong sense of the danger there is of checking the fair trial of this promising method by the hasty extension of it to cases forbidden by Dr. Schott, and against which he especially warns us. Worked carefully and conscientiously on the lines laid down by its originator it seems capable of being usefully introduced into our hospitals, into private practice, and especially into the practice of physicians at watering-places like Droitwich and Buxton, where many cardiac patients go annually for the treatment of their rheumatic and gouty ailments.

The system is fully at work at Llangammarch: Mr. Armstrong has been pursuing it for the last two years at Buxton, where he has arranged very good baths in a hydropathic establishment, and has nurses trained to conduct the exercises. I believe it is also carried out at Sidmouth, and I hope Dr. Roden will be able very shortly to give a fair trial to the Schott method in conjunction with the brine baths of Droitwich, modified to correspond with those of Nauheim.

We who have not the advantage of practising at health resorts know the drawbacks which attend any attempt to carry out systematic treatment on patients who are not detached from their business or domestic cares or their ordinary pursuits and pleasures, and for this reason its introduction into family practice will be limited. But in hospitals, where the patients are completely under control, I trust a fair trial may be given to it, for it is of importance that we should accumulate a wider experience than we already possess before we can say more than that it offers a fair prospect of success. There is one large group of cases in which private practitioners may be able to apply this treatment with advantage. I refer to the numerous cases of weakened heart after acute diseases: acute rheumatism, scarlatina, influenza,

etc., which are at present allowed to take their chance of strengthening under the not always satisfactory plan of ordinary walking exercise, the regulation of which is left very much to the patient's feelings and temperament. If, before any ordinary exercise were allowed, a course of Schott treatment could be carried out, it seems reasonable to hope that the heart would be better prepared to endure the less easily regulated a rain of walking.

From my small experience I would suggest that the effect of the baths should be tried first, and that afterwards when the exercises are introduced their influence upon the pulse rate and tension should be carefully watched, as they do not always suit irritable nervous hearts. Dr. Sturge's case is an instance in point, and the patient in the General Hospital with Graves's disease, whose heart slowed and improved in the bath, was not benefited by the exercises—that is, the pulse was not slower or improved in character or rhythm.

ON THE TREATMENT OF DISLOCATION OF THE PERONEUS LONGUS TENDON.

By W. J. WALSHAM, F.R.C.S.,

Assistant-Surgeon, Lecturer on Anatomy, and Surgeon in charge of the Orthopaedic Department, St. Bartholomew's Hospital.

DISLOCATION of the peroneus longus, though perhaps not very common, is a well-recognised condition. The dislocation may occur suddenly, as the result of a twist of the foot; or the displacement may take place slowly through the gradual yielding of the fibrous sheath. In either case it is found that the tendon during certain movements of the foot slips from its groove from behind the external malleolus on to the external surface of that process. The displacement gives rise to much lameness, pain, and inconvenience, and the treatment hitherto recommended has not, as far as I know, proved very efficacious.

When the dislocation occurs suddenly, pain is experienced at the moment of the accident, and the tendon can be felt crossing the outer surface of the malleolus, or slipping in and out of its groove on moving the foot. Subsequently the tendon is liable from time to time to be spasmodically jerked out of its groove with a smart snap, which can be felt by the patient and heard by the observer.

No pressure with the fingers or with any apparatus with which I am acquainted is sufficient to resist the force with which the tendon is thrown forward during the spasm of the muscle on to the outer surface of the malleolus. The spasmodic displacement gives rise to considerable pain, often rendering walking without a stick almost impossible, and of course putting active exercise, such as dancing, tennis playing, etc., out of the question.

The apparatus usually advised in our works on surgery, namely, a crescent shaped, graduated pad placed over the tendon and fixed by a lacing ankle-piece, is, in my experience, of little service. Either the pressure is insufficient to confine the tendon to its groove, and it slips out occasionally in spite of the pad, or if the pressure is increased sufficiently to confine the tendon, a pressure sore soon forms. The division of the tendon with or without twisting of its proximal end for the purpose of causing it to inflame and so adhere to its sheath, though recommended by some surgeons, seems at the best to have little to be said in its favour. The spasmodic jerking of the tendon over the malleolus is no doubt prevented, but the function of the tendon is lost, and the patient in the future subjected to the many evils attending paralysis of the peroneus longus.

In a case recently seen with my friend Dr. Cooper Key, we conceived that it would be possible to make a new sheath for the dislocated tendon, a procedure as far as I know that has not hitherto been done or proposed. The operation consisted in making an incision about three inches in length over the tendon as it lies behind the external malleolus, exposing the malleolus and lower end of the fibula, and turning down from it a flap composed of the thickened fascia and underlying periosteum. The flap was then carried over the tendon and sutured to the fibrous tissues lying at the back of its normal groove. In the case in which this operation was performed, although—and notwithstanding strict antiseptic precaution—some suppuration occurred, the result was eminently satisfactory; the patient who for four years previously had been lame and compelled to walk with a stick, and had been debarred from all active exercise, when last heard of was able to walk quite naturally and well. The tendon remained in its groove and could be felt sliding in it freely on the various movements of the foot. A brief note of the case is appended:

A young lady, aged 22, four years ago whilst skating caught her foot in a hole in the ice, sustaining a severe sprain of the ankle. Ever since she has been lame, and from time to time during walking the peroneus springs forward with a distinct and audible snap, giving rise to a sharp and momentary attack of sickening pain. She has worn various kinds of bandages, anklets, and specially made boots, but they have been of little or no service. She has also worn a night instrument for fixing the tendon. Of late she has used a boot with outer and inner leg irons, with T-strap and specially shaped pad lacing over the tendon. At the present time she has a pressure sore from the use of the pad, which has now, under Dr. Cooper Key's care, almost healed. On January 17th, the pressure sore having quite healed, the operation above described was performed, and the tendon having been satisfactorily fixed by the new sheath in its groove, the skin wound was completely closed and the foot placed in plaster-of-paris. Some slight suppuration occurred. On March 6th, the note states: The wound soundly healed; the tendon moves freely behind the malleolus, and shows no tendency to displacement. The patient walks well and has no pain, but the ankle feels a little stiff after sitting any length of time. Ordered massage. May 17th, excellent result in every way. The tendon moves freely, it does not come out of groove. She can walk five or six miles without any lameness or inconvenience.

At the meeting of the International Congress of Zoologists a communication which excited a great deal of interest was one from M. Dubois, a surgeon in the Dutch army, who has discovered a large number of fossil remains in Java, including fragments which indicate the existence of a creature, it is claimed, nearer to the "missing link" than anything yet discovered. A discussion followed, in which Professor Virchow took the principal part. During the Congress it was announced that the Senate of the University of Utrecht had conferred the degree of Doctor in Zoology and Botany upon Sir William Flower.

ON THE PATHOLOGY AND CLINICAL HISTORY OF SOME RARE FORMS OF BONY ANKYLOSIS.¹

By HOWARD MARSH, F.R.C.S. Eng.,

Surgeon to and Joint Lecturer on Surgery at St. Bartholomew's Hospital, Consulting Surgeon to the Hospital for Sick Children.

Not many years ago all that was taught about bony ankylosis could be summed up in two propositions: (A) That the only manner in which a joint could recover after it had been involved in suppuration was by the development of bony ankylosis. (B) That there was only one cause for bony ankylosis, namely, suppuration. It is now known that neither of these propositions is correct. (A) Suppuration is not necessarily, either in acute or chronic cases that recover, followed by bony ankylosis. This is illustrated in regard to acute cases, in pyæmia, acute suppurative arthritis following wounds, the acute arthritis of infants, and in other instances. In all these conditions, if the joint concerned is freely opened, irrigated, and drained aseptically, perfectly free movement may be preserved. Sometimes, if a joint distended with pus, as the consequence of pyæmic infection is merely evacuated by aspiration, complete repair follows. Generally, however, when acute suppuration involves a joint, unless efficient treatment is at once employed, ankylosis will take place; but then, in the majority of cases, it will not be bony but fibrous in its character. Undoubtedly some of the most complete examples of bony ankylosis that can be found are those which have followed acute suppuration. But the point I wish now to emphasise is that bony ankylosis does not necessarily, or even commonly, follow acute suppuration. In chronic cases attended with suppuration bony ankylosis, instead of being the rule, is quite the exception. Thus, in tuberculous disease—for example, of the hip or the knee—should ankylosis follow, this, in the great majority, will not be bony but fibrous. (b) Bony ankylosis often occurs in joints quite independently of the suppurative process. It is to this part of the subject that I wish to invite particular attention. Bony ankylosis, apart from suppuration, is met with in the following groups:

1. *In Tuberculous.*—All are familiar with four results of tuberculous joint disease: (A) Perfect recovery when treatment is adopted early, and is adequately carried out. (b) Fibrous ankylosis; this, in a degree which varies widely in different instances, is very common. (c) Bony ankylosis after suppuration—as is seen, for instance, sometimes after hip disease. (d) Complete destruction of the articulation, calling for excision or amputation. But there is a fifth group. (e) In this group inflammation is from the first plastic, and is followed by the development of complete synostosis. In these cases the inflammatory process is never active. There is little, if any, alteration of the articular ends, and the usual symptoms of inflammation—swelling, heat, and pain—are so little marked that the condition of the joint may for some time entirely escape notice.

CASE I.—A girl, aged 11, in bed with Pott's disease, was found to have her elbow completely stiff. She had complained of no pain, and the only thing her mother had noticed was that she used the limb awkwardly in feeding herself. On examination the elbow joint presented a natural appearance, but it was completely stiff, and the muscles were wasted. The stiffness proved to be permanent.

CASE II.—A girl, aged 9, had tuberculous disease of her knee. There was some synovial swelling, accompanied by flexion and slight heat. Leather splints were applied. Heat and swelling gradually subsided, but the joint became completely stiff. The child has now been using the limb freely for the past five years, and the knee is still quite fixed.

I believe that in both these cases bony ankylosis has occurred. Of course there is no proof of this without maceration of the specimens, and examination of them in longitudinal section; but that bony ankylosis may occur in such instances is proved by the following example.

CASE III.—The elbow joint of a girl, aged 14, had gradually, without symptoms, become fixed at an angle of about 130°.

To improve this position Dr. Walter Broughton, of New Barnet, performed excision. During the operation he found that complete bony ankylosis had taken place. (See Fig. 1.)

Fig. 1.—The elbow-joint seen in longitudinal section. The humerus and olecranon are completely synostosed.

This specimen is of great value. It is the only one of its kind that I have seen.

I have met with several instances in which tuberculous joints have become thus quietly completely stiff. It seems important to bear these plastic cases in mind. I know of no method by which bony ankylosis can be averted. It takes place, as the above examples show, whether or no splints are used, but should it occur while the limb is in splints the patient and his friends will ascribe it to the treatment that has been adopted.

I believe that this plastic form of tuberculous inflammation may also involve the spinal column. Fig. 2 shows two

Fig. 2.—Complete bony ankylosis between the bodies and neural arches of the second and third cervical vertebrae (No. 1075, Museum of St. Bartholomew's Hospital).

¹ Read in the Section of Surgery at the Annual Meeting of the British Medical Association held in London, July-August, 1895.

cervical vertebrae very firmly ankylosed. They are not altered in shape, or eroded even superficially. No history of the specimen is known; but I believe the condition has resulted from tuberculous inflammation, followed by the organisation of the inflammatory products into bone.

2. I would now ask whether bony ankylosis occurs in Charcot's disease, apart from suppuration attending perforating ulcer? The great majority of observers, I believe, would answer in the negative. Yet, I think, there is evidence to throw some doubt on this conclusion.

Charcot² has described a tabetic foot in which the under surface of the astragalus presented bony vegetations. The scaphoid and cuboid were scarcely recognisable, and the internal cuneiform was fused with the first metatarsal, and the middle cuneiform with the second metatarsal bone. All the tarsal and metatarsal bones were spongy and friable. Charcot remarks that these complex lesions, occurring apart from traumatism and suppuration, can only be classified as definite osseous and articular changes accompanying tabes.

Fig. 3.—Bony ankylosis of the foot (Museum of the University of Cambridge).

Fig. 4.—Bony ankylosis of the foot. Some of the tarsal joints are obliterated, but others are but little changed, and ankylosis is due to the formation of plates and vegetations on the surface of the bones (Museum of the University of Cambridge).

Figs. 3 and 4 represent two remarkable skeletons of feet, kindly lent to me by Sir George Humphry, from the Museum of the University of Cambridge. These feet are the seat of almost universal bony ankylosis, owing to the fact that the superficial surfaces of the different bones are covered with vegetations and continuous bony deposits, which bridge over the intervals between them. On section, however, it is discovered that some of the tarsal joints themselves are very little changed. Their cavities can still be traced, and even the articular cartilages can be recognised. Some of the tarsal and phalangeal joints, however, have undergone such complete synostosis that no vestige of their cavities remains. The history of the cases from which these specimens were derived is unfortunately unknown. I have never seen such conditions before. How are the appearances to be explained? At first sight they might be attributed to suppuration—possibly of septic origin. But, in the first place, there is very little alteration in shape, and very little erosion of the bones,

such as would be expected in widespread suppuration; secondly, many of the joints are but little changed; yet in septic cases it is upon the joints themselves, through their synovial membranes, that the main stress falls; thirdly, the sesamoid bones of the great toe are much increased in size—a change that, so far as is known, could not be produced merely by inflammation going on to suppuration. The complete bony ankylosis which is present in some of the phalangeal joints is a condition that may follow suppuration. But here, again, the bones are not eroded or altered in shape; they are simply synostosed. The formation of osteophytic outgrowths and low buds and vegetations, which is so marked a feature in these specimens, and which was present in Charcot's case, is well shown in a tabetic foot in the Museum of St. Bartholomew's Hospital (No. 691x). In this specimen, although no suppuration had occurred, the tibia and the fibula are ankylosed together by bone. These examples appear to show that bony ankylosis, apart from suppuration, may occur in Charcot's disease.

3. In a case in which the median nerve had been divided and the hand had become clawed, Mr. Bowly found³ that bony ankylosis had occurred in one of the interphalangeal joints of the ring-finger, while several of the other finger-joints were stiff, although as yet ankylosis had not taken place. This specimen is the only example of bony ankylosis after nerve-section that I have met with.

4. It is well known that in gout and (5) gonorrhoeal rheumatism bony ankylosis occurs entirely apart from suppuration.

6. In some instances severe contusion of the articular surfaces of a joint may be followed by bony ankylosis. I have seen this result follow in the temporo-maxillary joint after a heavy fall upon the chin.

7. Bony ankylosis is not very uncommon in the spine in the more extreme forms of lateral curvature. It has occurred in specimens No. 2103 and 2104 in the Museum of the College of Surgeons and in 252 and 254 in the Museum of St. Thomas's Hospital. The vertebrae are fused together in the concavity of the curve. Similar examples may be found in almost every large pathological museum.

8. I now pass to a group of cases in which multiple bony ankylosis has occurred where no suppuration has taken place.

CASE IV.—In 1889 a groom, aged 22, was admitted into St. Bartholomew's Hospital. Four years before he was said to have had rheumatic fever, for which he was in bed for thirteen weeks. At the end of this time he was able to walk, but his joints gradually became stiff, and for three years he had been bedridden. On his admission the hips and knees were flexed, and the feet were in a position of talipes equinus. All the joints of the lower extremities were firmly fixed. His remaining joints were all free. Beginning with the right limb, I performed, on successive occasions, in order to remove deformity, osteotomy of the ankle, excision of the knee, and osteotomy of the femur below the trochanters. After the last operation the wound suppurated. He was at the time in very poor general health, and, developing lardaceous disease, he ultimately died of exhaustion. All the six large joints of the lower extremities proved to be ankylosed by bone.

CASE V.—Dr. Hilton Fagge relates the following instance.³ A man, aged 34, was admitted into Guy's Hospital in 1874. In the previous year his spine became stiff, and formed a rounded curve; later the right hip became fixed. He died of chest troubles following difficulty of respiration. At the post-mortem examination the arches and the spinous processes of the dorsal vertebrae were found completely ankylosed, and so were the articular processes (Fig. 5). The vertebrae were much softened, and could be cut with a knife, and the spine had become fractured in placing the body in the shell. The ribs were firmly and extensively ankylosed to the vertebrae. The right hip was also ankylosed.

CASE VI.—Dr. Griffiths, of Cambridge, has given me notes of the following case. Three years ago a woman, aged 20, had the first phalangeal joint of the index finger swollen and painful. Pain and swelling after a time subsided, but the joint was left ankylosed. Other finger-joints underwent similar changes, then the wrists, and later the elbows swelled and were painful, and they also ultimately became quite

² St. Bartholomew's Hospital Museum.
Polth. Soc. Trans., vol. XXVII, p. 77, p. 204.

³ *Progrès Médical*, 1887, p. 604.

stiff. In an attempt to improve the position of the left elbow the bone was fractured. At the present time several finger-joints, both wrists, and both elbows are quite stiff. Some other joints are rather swollen, but in several Dr. Griffiths finds no swelling, no nodules, and no thickening of the bones. The ankles are swollen, but movement in them is free. The knees are somewhat swollen and stiff, other joints are natural.

I have mentioned that bony ankylosis may occur in the spine in tuberculous disease, in lateral curvature, and, in such cases as that recorded by Dr. Fagge.

Fig. 5.—Dr. Fagge's specimen of bony ankylosis of the spine (*Trans. Path. Soc., vol. xxviii, p. 209*).

Fig. 6.—Ankylosis of the spine produced by ossification of the anterior common ligament (Museum of the University of Cambridge).

8. It is well known that bony ankylosis is also common in the spine in Osteo-arthritis. On examining specimens illustrating this condition—and they can be found in any large museum—it is seen that the ankylosis is produced either by (a) ossification of the anterior common and other ligaments (Fig. 6), or (b) by the formation of buttresses of bone passing from one vertebra to another (Fig. 7). In many instances the ribs are firmly ankylosed to the bodies

Fig. 7.—Ankylosis of the spine produced by the formation of bony buttresses (Museum of the University of Cambridge).

and transverse processes of the vertebrae by ossification of the costo-vertebral and costo-transverse ligaments.

On making a longitudinal section of the spinal column, it is found that the ankylosis is entirely limited to the external surface of the vertebrae. The spaces between the bodies, which are occupied by the intervertebral discs, are seen in dried specimens to be in no way encroached upon. It will thus be observed that bony ankylosis, apart from suppuration, may occur in the spine, as in the limbs, in three different ways: (a) by direct and complete fusion of the component bones (Fig. 5, Fagge); (b) by ossification of the ligaments (Fig. 6); and (c) by the development of bony buttresses or plates, the joints remaining unaffected (Fig. 7). I may add that bony ankylosis may involve the spine only, or the spine may be involved in common with the limbs.

I have ventured to bring these different forms of bony ankylosis without suppuration under the notice of the meeting, first, because it may be useful to collect and arrange them for clinical study; and secondly, in the hope that those who take part in the discussion may throw some light on their pathology. The examples I have related seem to show that bony ankylosis is sometimes a reparative and sometimes a degenerative process. When it occurs in acutely inflamed joints, for example in the course of pyæmia or of acute suppurative arthritis following a punctured wound, bony ankylosis is reparative, and closely resembles the union of a fracture. It is reparative also when it occurs in tuberculous disease of the joints or spine. In all these instances inflammatory exudation is converted into normal bone to the advantage of the individual concerned. In other cases bony ankylosis is associated with and is a part of wide degenerative changes in the structures involved. In Fagge's case, as already mentioned, the vertebrae could be cut with a knife, and the spine had been fractured while the body was being lifted to place it in the shell. It was degenerative in the case recorded by Charcot and in the feet lost by Sir George Humphrey. It is degenerative, again, in gout and other nerve injuries, as well as when it is multiple, as in Case IV. It must be termed degenerative also where it replaces the normal structures by a tissue which is inappropriate for the discharge of the func-

tions of the part, for example, in ossification of the ligaments of the spine, and of the joints and ligaments of the ribs.

The true pathology of many forms of bony ankylosis, such as those illustrated by Cases iv, v, and vi, is at present, I believe, unknown.

I will not occupy the time of the Section by entering at any length on the clinical aspect of cases of bony ankylosis. I will only enumerate four propositions: 1. Whenever this condition seems likely to occur, great care should be taken to keep the joint concerned in a useful position. 2. We know of no means by which a threatened bony ankylosis can be averted. 3. The use of passive movements cannot prevent bony ankylosis. Indeed, by maintaining irritation and promoting inflammatory exudation, it is likely to produce a directly opposite result. 4. When bony ankylosis has occurred, excision or osteotomy may be freely employed, in order to correct any deformity that has taken place, for by methods that are now available these operations are attended with scarcely an appreciable risk.

[The author is indebted to Messrs. Cassell and Co. for permission to reproduce these illustrations from his work on *Diseases of the Joints and Spine* (Cassell and Co., 1895).]

Mr. TARBET laid stress on the distinction between ossification of the vertebral joints and of the ligaments, comparing the latter to myositis ossificans. He had never seen ossification in Charcot's disease without previous suppuration, that is, perforating ulcer. The disease was almost always attended with atrophy of bone, which was not shown in the specimens exhibited. He therefore doubted whether Charcot's disease was present in these cases. The most rapid and complete ankylosis without suppuration was found in puerperal fever and other kinds of sepsis. Dr. Fagge's case may have been one of quiet tuberculous ankylosis, since there were tuberculous deposits in the mesenteric glands.

Mr. BOWLY remarked that in one of the feet shown there had undoubtedly been suppuration, which, however, was far anterior to and quite independent of the ankylosis. The case was one of undoubted tabs. In his case of ankylosis following injury to the median nerve there was partial ankylosis of all the joints of the hand. After nerve injuries the joints supplied by them undergo changes somewhat like those in acute rheumatism, becoming swollen, tender, and partially ankylosed. These changes are not, as a rule, permanent, but there may be a deposition of fibrous tissue in the ligaments, particularly on the flexor surface of the hand, often leading to permanent stiffness. He agreed with Mr. Marsh's division of bony ankylosis into degenerative and reparative. He also pointed out that many joint lesions were due to disease of the central and peripheral nervous system, such as syringomyelia and disseminated sclerosis, and said that in the near future osteoarthritis would probably be shown to have the same origin. Mr. Bowlby believed that many cases of bony ankylosis without suppuration lie latent in museums through having no histories attached.

Mr. BLAND SUTTON refused the title of quiet tuberculous as applied to the axis and cervical vertebrae shown by Mr. Marsh, on the ground that the time of life was too late. Similar specimens, with the occiputs joined on, were to be found in most museums. Many had been turned up in graveyards, and one was found in a mummy from the Pyramids. The condition was not thoroughly explained in all cases, but Mr. Arbuthnot Lane had suggested that the skeletons were those of costermongers and others accustomed to carry weights on their heads. Mr. Sutton had confirmed this in the case of the Paris oxen, which are yoked by the horns. He also pointed out that in the veterinary museums at Alfort and Camden Town there are numerous skeletons of horses showing ankylosis due to ossification of the anterior common ligaments and ligamenta subflava. This may cause snapping of the vertebral column in horses cast for operation.

Mr. ELLIS (Gloucester) referred to the condition known as hallux flexus, rigidus or dolorosus, which he considered due to the outward pressure of the median-pointed boot pressing the great toe under the adjoining ones. The joints most exposed to irritation are most subject to this disease, and ankylosis is here reparative.

Mr. MARSH, in answer to Mr. Bland Sutton, said that in his experience tuberculous disease of the spine might occur

with well-marked angular curvature up to the age of 70, and he had heard of it at 90. Ankylosis of the spine from ossification of ligaments was more than a pathological curiosity in man; if it was complete the patient was very helpless; and when it was associated—as was often the case—with ankylosis of the ribs, it was very likely, if bronchitis or pneumonia occurred, to interfere with respiration so seriously that the result was fatal.

ON SPLENECTOMY, WITH NOTES OF THREE CASES.¹

By W. D. SPANTON, F.R.C.S. Eng.,
Surgeon to the North Staffordshire Infirmary.

I HAVE now performed the operation of splenectomy three times—two of the cases being followed by a fatal result, one by recovery—and they are sufficiently typical to afford an opportunity to consider the subject in its general aspect, and to endeavour to deduce from them some observations of practical importance. It is only during the last few years that the propriety of such an operation has gained favour. In this respect the operation stands by no means alone, for almost all formidable surgical procedures have had to pass through a similar ordeal, and it is only by experience that we are enabled to eliminate cases unsuitable for operation, and to perfect our methods of performing it so as to render it at the same time justifiable and reasonably safe. The records of the cases are as follows:

CASE I.²—Mrs. S. B., aged 47, married, admitted into North Staffordshire Infirmary under Mr. Spanton, September 1st, 1893. Patient always strong, no illness until the present. Twelve children, all living, youngest 4 years old. Never been abroad, and never lived in ague district. Illness commenced two years ago with pain and enlargement on left side of abdomen. She thought at first that she was pregnant. The pain has never been very acute, but chiefly of a dragging character.

The enlargement of the abdomen increased gradually, and twelve months ago she became an in-patient in the medical wards on account of the inconvenience it caused her. At that time she was able to get about to do her household work, and was fairly stout and strong.

The tumour then was very distinct, and had all the characters of an enlarged spleen. It extended to within about 1½ inch of Poupart's ligament; in fact it covered nearly half the abdomen. Since leaving the infirmary she has been under medical treatment outside, but without any benefit resulting.

There had been no ague fits or any attacks of that nature before her first admission, but during the last few months she has sometimes felt cold, which has been followed by a free perspiration. For the last twelve months she has lost flesh rapidly and has got so weak that she cannot get about to do anything. Digestion fairly good, no sickness, no marked anaemia, catamenia absent for about twelve months.

Urine contained phosphates but no albumen. Blood examined under microscope was found to present no marked deviation from a normal specimen; the white corpuscles were not increased and the red ones were well formed. The patient had an anxious expression, appeared much troubled about her complaint, and was prepared to submit to any operation. She suffered from severe pain in the head and in the abdomen while in the infirmary, and the temperature varied from 100° to 103°F. She had no distinct shivering attack but perspired much when the pain was most severe. A consultation was held and it was decided to operate, but on account of her condition it was thought advisable to postpone it until the temperature had subsided.

On September 11th she seemed much better, the pain was less and the temperature was only 99°F. It was therefore arranged for the operation to take place on the following day.

The patient was removed to Victoria Ward on September 12th, but no purgative was given and no enema administered because a few days before she had a tendency to diarrhoea.

¹ Read in the Section of Surgery at the Annual Meeting of the British Medical Association, held in London, July-August, 1893.

² This case was briefly reported in the *BRITISH MEDICAL JOURNAL*, 1893.

September 12th. In very good spirits, very little pain except in the region of the spleen, temperature 99°F., no diarrhoea, slight cough, and a few rales audible on the right side of the chest, but no dulness on percussion and no physical sign on the left side.

The tumour was smooth on the surface, very hard, and extended from the fifth rib above to Poupart's ligament below; forward it extended across the middle line to the outer margin of the right rectus. The notch could be felt two inches below the umbilicus, and one inch to the outer side. The margin above and below this was smooth and regular, convex from above downwards, with the convexity towards the right. The tumour could be lifted forwards by pressure in the left flank, and the right margin was sufficiently thin for the hand to be passed behind it. In front, where the experiment was practicable, the abdominal wall could very readily be separated from the tumour. It occupied a larger portion of the right side of the abdomen when the patient lay on her right side, but quickly assumed a different position when the position of the patient was changed. The liver dulness extended a little distance below the ribs, there were no enlarged glands in the axilla or groin, and no congestion of the superficial veins of the abdomen. The heart was normal.

The operation was commenced at 4.40 and concluded at 5.55. An incision was made in the median line, from near the xiphoid cartilage, 9 inches downwards. The small lobe of the liver first came into view, and next the great omentum; the omentum was drawn to the right, and the spleen was then exposed; it had a very congested appearance, and the veins of the great omentum were considerably enlarged. The spleen was lifted upwards, and a large vessel ligatured beside some smaller ones.

It was proposed to pass one large ligature round the base of the tumour as a preliminary measure, but this could not be done without breaking down its connection with the diaphragm. Many vessels were also ruptured in the attempt. Two ligatures were, however, passed in this way, the one from the inner and the other from the outer side. The spleen was then quickly removed, and it was found that the ligature had secured most of the vessels.

Some smaller ones were tied with thick silk, and Tait's clamp was applied to that part of the pedicle formed by the gastro-splenic omentum. The large vessels were tied with whipcord, by means of a double threaded aneurysm needle. There was a considerable amount of hæmorrhage at the commencement of the operation, for in the endeavour to lift the spleen from its bed, some vessels on its under surface were ruptured, but after these had been secured there was no great hæmorrhage throughout the operation. The amount of blood lost was estimated by those present at a pint.

After the clamp had been applied all hæmorrhage appeared to have ceased. A small lateral incision was made in order that the clamp might be brought to the surface, and secured without any tension in the pedicle. The whole wound was then closed by means of silk sutures, the clamp lying over the left rectus in a vertical direction. The spray (Sanitas) was playing over the patient before the operation, but was discontinued when the incision had been made. The wound was dressed antiseptically. During the removal of the spleen the bowels were prevented from protruding as far as possible by means of warm chamois leather and sponge cloths.

The pulse was good after and during the operation. The patient was removed to the bed which was at the side of the operation table, and an enema of brandy and milk given. She soon rallied and was able to describe her symptoms. She said she felt sick but had very little pain. The retching was troublesome, but otherwise everything appeared to be going on favourably. The pulse remained good.

At about 9.20 p.m. she became suddenly worse, and the nurse noticed her colour change, and the breathing became "gaspings." When seen by the house surgeon a few minutes afterwards the pulse had nearly disappeared, and from the dusky appearance of the countenance and the character of the breathing internal hæmorrhage was diagnosed.

A consultation was held with Mr. Spanton by means of telephone, but under the circumstances it was not thought advisable to reopen the wound.

Death occurred at 9.50 p.m. Weight of spleen, 8 lbs. 1 oz.

(after draining). Measurements, 11 inches by 8 inches, by $\frac{5}{8}$ inches greatest thickness. Structure simple hypertrophic.

At the post-mortem examination eighteen hours after death rigor mortis was well marked. The abdominal cavity contained about a pint and a-half of blood, chiefly clotted; a large silk ligature was found lying loose on the blood clot, but the mouth of a large vessel could not be detected. The kidneys were normal, heart normal, liver enlarged but otherwise healthy. The lungs had the character of bronchitis, which was more marked on the right side and at bases. The brain was not examined.

Remarks.—The fatal result in this instance was clearly due to hæmorrhage, although at the time of closing the wound everything seemed secure. The pedicle was very large, and the vessels in it enormous, and this led me to leave on it the clamp as a safeguard. The bleeding probably occurred in this, as in some other recorded cases, from a vessel not included in the main pedicle, and the loose ligature pointed to this, although no open mouth was apparent. In the light of more experience I think that if the suspensory ligament had been dealt with first the result might have been different. The tumour was very large, very friable, and the pedicle was comparatively short, all of which tended to make excision more difficult, especially in one's first operation of the kind.

CASE II.—Mrs. M., aged 59, married, admitted into the North Staffordshire Infirmary, January 30th, 1891, for enlarged spleen. Patient says she was quite well until eighteen months before, when she had typhoid fever, and was never well after. She had, however, been subject to epileptic attacks for some years. About a year before admission she first noticed a lump in the abdomen, which was then about the size of an orange, and steadily increased. Latterly she had become much paler, and suffered from severe attacks of sickness.

In the autumn of 1890 she was a patient in the medical wards for anemia; had become much weaker since then; for the last month had been confined to bed, and was unable to stand without help.

On admission she was pale, emaciated, and feeble. Had frequent attacks of severe vomiting, accompanied by diarrhoea and often dyspnoea. Systolic murmur at base. Chest signs negative. Abdomen: A large firm tumour felt occupying left hypochondriac, iliac, and umbilical regions, extending to the middle line and downwards to a point $2\frac{1}{2}$ inches below umbilicus. A very distinct notch could be felt just above the level of the umbilicus. It was freely movable, and caused pain of a dragging character. The blood showed an excess of white corpuscles relatively to red. Urine was normal. After consultation it was decided to perform splenectomy, as the patient was steadily and rapidly losing ground after a full trial of medical and general treatment.

Operation, February 3rd, 1891.—Chloroform. An incision, 10 inches in length, was made in the left linea semilunaris, and the spleen readily exposed. There were no adhesions, and the tumour was withdrawn without difficulty. The pedicle was transfixed and tied with five interlocking silk ligatures, and divided. The bleeding was slight. Wound closed with silk sutures; no drainage. Alarming symptoms of collapse occurred when the tumour was being drawn out of the abdomen, but passed off after it was separated. The patient, however, never thoroughly rallied from the shock, and died eleven hours afterwards.

The tumour weighed $5\frac{1}{2}$ lbs., and appeared to be simply hypertrophic. *Post mortem* a considerable quantity of blood clot was found in the peritoneal cavity, but no open vessel nor loose ligature was seen.

Remarks.—In this case the patient was in a wretched state of health, although there was no very marked leucocythæmia. In fact, she remained florid to the last, but became much emaciated, so that she was confined to bed for some time before operation was resorted to. There was some hæmorrhage, it is true, but the death was, I think, attributable to shock, which was almost fatal during the operation. The pedicle was wide and short, so that it was difficult to avoid dragging upon it while the ligatures were being applied. I think, too, it would have been better had ether been employed as an anæsthetic.

CASE III.—I was asked by my friend, Dr. Coulson Bull, to see Mrs. E., married, aged 38, on account of an abdominal swelling, to which the patient's attention had been drawn owing to severe pain in the left hypochondrium, which Dr. Bull attributed to localised peritonitis. She was then suffering much, and we came to the decision that the tumour was splenic and demanded operation. She was therefore admitted into the North Staffordshire Infirmary, and the following notes were then made by the house surgeon, Mr. Sawers:

Admitted February 27th, 1895, complaining of a swelling of abdomen on the left side, and pain of a dragging character.

History.—For the last four years the patient had had a heavy dragging pain in left hypochondrium, worse when moving about. Since Christmas, 1894, she noticed that she was getting larger, and that there was a tumour in the left side of the abdomen, which had become rapidly larger during the last few weeks. She had lost flesh, and been subject to profuse perspirations.

Present State.—A rather spare woman, with little subcutaneous fat; lips a good colour, skin somewhat sallow, cheeks flushed, tongue clean and dry. Abdomen distinctly fuller on left side. There is a readily felt tumour occupying the left hypochondrium, lumbar, and umbilical regions. The anterior border reaches from the tip of the left ninth rib to about 2 inches below the umbilicus, and at its lowest point touches the middle line. The border is rounded and firm; no definite notch can be made out. The lower border runs somewhat upwards and outwards. The tumour does not completely fill

up the loin, there being felt a posterior border which runs vertically upwards from about 1 inch behind the anterior superior spine of the ileum to the margin of the ribs. The tumour is everywhere firm to the feel, is somewhat tender, especially posteriorly, and moves on respiration. Percussion note dull all over tumour, and dulness extends upwards to the level of the eighth rib in the mid-axillary line. Measurements—anterior border, 6 inches; greatest breadth, 7 inches; length of absolute dulness, 11 inches. Blood corpuscles were counted, red 80 per cent.; no increase of white corpuscles. Urine normal, heart normal, chest normal except slight crepitation at left base.

Operation, March 11th.—Ether. An incision about 6 inches long was made in the left linea semilunaris, commencing just below the costal margin. The spleen then came into view, and was partially brought forward through the wound. A few adhesions between the surface and the abdominal wall were ligatured in two places and cut through. The suspensory ligament was then double ligatured and separated, and the spleen then easily brought outside. The pedicle was transfixed with a blunt needle, and tied in two portions, one of which included the splenic artery before its division, the ends of one of the threads being carried round the whole and tied. Strong silk was used. The pedicle was then divided and the spleen removed. The splenic artery and vein were ligatured separately afterwards; the wound closed with deep and superficial silk sutures. Very little blood was lost during the operation, which lasted about thirty-five minutes.

NOTES ON SPLENECTOMY, DERIVED FROM THE TABLES.

(1) TABLE I.—*Leucocythæmia*: 25 cases (2 males, 23 females); 24 died. Death rate 96 per cent. The case that recovered (a woman) is considered by Knowsley Thornton to have been one of simple hypertrophy.

(2) TABLE II.—*Non-Leucocythæmic* cases: 105 cases (52 males, 53 females); 52 recovered; 53 died. Death rate 50.5 per cent. The following are the details of the table:

	Cases.	Recovered.	Died.
(1) Hypertrophy	5	15	21
(2) Wandering	9	2	7
(3) Rotated	2	2	0

	Cases.	Recovered.	Died.
(4) Lymphosarcoma	2	2	0
(5) Cystic, including hydatid	4	4	0
(6) Other cases, including injury	4	2	2

Death rates for each of the last three decades (exclusive of *Leucocythæmia*).

	Number of Cases.	Deaths.	Death rate, per cent.
1860-75	5	2	40.00
1876-90	20	0	0.00
1891-00	20	6	30.00

The tumour was examined by Dr. S. King Alcock, who reported as follows: "Weight was 6 lbs. 4 ozs. The structure is practically normal throughout, and there is no excess of fibrous tissue, the capsule being exceptionally delicate."

Patient bore the operation well. For the first two hours she was somewhat collapsed. After that time the temperature rose rapidly, and at 6 P.M. was 103° F., pulse 180, perspiring very freely, complaining of severe pain in the region of the spleen. No vomiting. At 9 P.M. temperature 100° F., pulse 124. A hypodermic injection of morphine was given.

March 12th. Passed a good night, slept about four hours; still much pain; passed flatus and urine. Temperature 98.4°, pulse 108; much thirst; ordered enema of warm water.

March 13th. Still much pain, cough troublesome, perspires freely. Temperature 99°, pulse 116. Wound looking healthy and dry.

March 14th. Less pain, taking food well.

March 17th. Very comfortable, hungry; had simple enema which acted well. Pulse 106, temperature 98.4°. Still perspiring freely.

March 19th. Sutures removed, wound quite healed, patient comfortable and cheerful. Temperature 98°, pulse 100.

March 22nd. Evening temperature rose to 105°, and complained of pain in left hypochondrium. No cause could be found. Tongue clean and appetite good.

March 23rd. Temperature again normal and pain gone.

March 31st. Since last note the temperature has risen each evening, ranging from 101.8° to 103.6°, and with this has always been associated pain over the site of the pedicle. From this date the temperature came down to normal and remained so. She rapidly gained strength and flesh, and returned home quite well on April 23rd.

The patient is now quite active, and says she feels better than she has felt for several years.

Remarks.—In this instance the patient had suffered more from actual pain than either of the others, owing to the peritonitis no doubt; and I am of interest to note that this in no way interfered with a satisfactory result. The signs of shock which came on suddenly as soon as I made an attempt to lift up the spleen led me to consider how to free it without dragging on the pedicle, and finding that it was held principally by the suspensory ligament I decided to deal with this first. After the division I was gratified to find that one could lift up the spleen without inducing any further signs of collapse, and it was then possible to reach the splenic vessels without difficulty before their subdivision, as already described. From a physiological point of view it is interesting to mention that a small splenulus was found in the gastro-splenic omentum, which was of course left untouched. One feature very marked in this case was also observed in the other two, the existence of very profuse perspirations before operation, which disappeared afterwards. In the absence of any signs of suppuration and of any marked rigors this is interesting. I cannot explain it. The rise of temperature occurring about the eleventh day after operation has been observed in some other recorded cases and was curious, lasting several days; it was no doubt caused by some inflammatory changes in the neighbourhood of the stump of the pedicle, some localised phlebitis most probably; but this is only what might be expected when one considers how largely the venous element is concerned in it. It serves to enforce the necessity of securing every vessel if possible, a point on which all operators are agreed. This patient is now (July, 1895) perfectly well, and leading a more active life than she has been able to do for the last four years.

Splenectomy has now been performed in this country sufficiently often to enable us to draw some conclusions as to the range of its usefulness. I have endeavoured to tabulate all the recorded cases up to the present time, including many which have already been published in the tables of Collier and Thornton and elsewhere. Mr. T. T. Cockill has traced out for me as far as possible every case which appears in the table; no doubt many operations have been performed which have not been put on record, both successful and unsuccessful, and these must necessarily be left out of calculation. We have, however, 84 cases, and some interesting data can be deduced from them. We find that among the leucocythæmic cases, out of 25 only 1 recovered. It is now generally acknowledged that splenectomy in such

cases is attended with too great a risk to be justifiable. This is not due to any greater difficulty in the operation, but to the gravity of the disease itself, which seems to render any surgical procedure most unsafe. So that we may, I think, accept the dictum laid down in the recent textbooks that in all cases in which leucocythæmia is present splenectomy ought not to be performed.

Among 38 cases of hypertrophy we find 20 deaths after operation. These are the cases which present themselves to the surgeon as causing most discomfort, and seem most to demand surgical interference. The solid mass dragging on the stomach and causing pressure on adjacent organs render life intolerable, and in many of them some form of local peritonitis is set up which adds to the pain and danger.

It will be observed that in all my cases the spleen was of considerable size, much larger than the majority of those I find recorded. In Case III it is much the largest among those who recovered.

It is curious how a solid tumour of this kind, of even moderate dimensions, will cause a much larger amount of discomfort proportionately to a fluid tumour of the same weight. In my third case this was especially marked, as the patient became very ill and emaciated from the constant dragging and distress caused by what proved to be a simple enlargement. As soon as this was removed her general health at once began to improve, and she rapidly gained flesh. This affords a strong reason for removal of the organ, which may be diverting material which ought to be utilised elsewhere.

Of the remaining other conditions for which splenectomy was undertaken we find wandering and rotated spleens; lymphosarcoma; cysts, including hydatid; injury, and abscesses.

Taking the last three decades, we have this remarkable result:

During the first,	1865-75	a mortality of 80.0 per cent.
" second,	1876-85	" " 45.0 "
" third,	1886-95	" " 20.68 "

For wandering spleen it would seem quite feasible to adopt splenorraphy, as we do in cases of wandering and movable kidney. I have not met with any instance which caused sufficient discomfort to warrant the procedure, though I would certainly be disposed to adopt it in a suitable case in preference to the great risk of splenectomy.

With regard to the operation itself, the chief risks appear to be shock and hæmorrhage. In a very large proportion of the fatal cases one or both of these conditions have been the cause of failure. So that our chief aim must be in the direction of averting shock and security against subsequent hæmorrhage. With regard to shock, it is easy to understand why it should be formidable from the intimate connection of the spleen with the large solar plexus, but in most of the recorded cases I find it was first noticed when an attempt was made to remove the organ from the abdomen. In my own cases this was most marked the moment the spleen was pulled upon by the slightest degree; and in my last case I was so struck by this, that it occurred to me that it might be caused as much by the dragging upon the diaphragm as by any interference with the gastro-splenic pedicle. Acting on this hint I decided to begin by dividing the suspensory ligament. This was transfixed, ligatured, and set free, and the moment this was done all signs of collapse or shock passed off. I think that this is an important point, for if we can in this way overcome the first tendency to shock and at the same time set free the pedicle proper, one of our chief difficulties is overcome. I found it quite easy to deal with the vessels in the pedicle, and it seemed to simplify the subsequent proceedings wonderfully. It may not be possible to adopt this course in some cases, but I feel sure that when it can be done it will greatly simplify the operation, and enable the vessels to be secured more readily and certainly.

I find in almost all the published records that the suspensory ligament has been dealt with last (as in my own first two cases) and I desire therefore to draw special attention to this matter. Then as to the best mode of securing the vessels, I think no rule can be laid down. Where the splenic artery and vein can be ligatured separately it is a great gain, but more often the vessel divides far before it reaches the spleen, and, as in my first case, a very broad pedicle with many vessels is what we must deal with.

If a double ligature will suffice that is probably the best, taking care after dividing the pedicle to put a separate silk ligature on each open mouth. Some of the deaths from hemorrhage have been attributed to a "small" vessel slipping from the main pedicle ligature, and the course I suggest will entirely frustrate this danger. At the same time it is very essential to ligature every bleeding point in any adhesions, for everything in this neighbourhood is usually very vascular.

In my successful case, every care was taken to tie any vessels and make everything secure, and yet the operation was completed in a little over half an hour. This, too, is important, not to keep the patient longer than is absolutely necessary under operation, and it is better to make a large incision so that the tumour may be easily removed and there may be ample room for dealing with the pedicle, with as little dragging and disturbance as possible.

When we consider that during the last thirty years, as shown by the table, the mortality with a larger number of cases has been reduced from 80 per cent. to 20.68 per cent. on the published cases, we may I think fairly say that splenectomy has a grand future before it, though the cases in which it must be demanded are few and far between; and it ought not in my opinion to be resorted to unless the patient's condition is such a miserable one as to demand it. Every other resource must be well tried first, though up to the present time the results of medical treatment in cases of true hypertrophy seem to have been most unsatisfactory.

The operation will probably be necessitated only in the case of injury and large tumours, non-malignant, whether solid or cystic; and I can hardly imagine its justifiability with the present rate of mortality, in any cases of small or simple movable spleens.

TWO CASES OF SUPPURATING HYDATID OF THE LIVER, PROJECTING BACKWARD, DRAINED THROUGH THE CHEST WALL AFTER RESECTION OF RIB.

By STEPHEN PAGET, M.A., F.R.C.S.,

Surgeon to the West London Hospital and the Metropolitan Hospital.

THESE two cases happened to come under my care almost at the same time, and they taught me so clearly the difficulties of diagnosis and of treatment that must always be present when a hydatid of the liver presses upward and backward, but not forward, that I venture to submit them to this meeting. The necessity of saving time must be my excuse for passing over similar cases reported by Mr. Tyson, of Folkestone, and other surgeons.

Instead of relating these two cases one after the other in the usual way, I will put the chief features of each case side by side, hoping in this way to show more clearly the conclusions to be drawn from them.

1. *Previous History of Case 1*.—The patient was a gentleman, aged 39; he had lived in England nearly all his life, and had never been in Australia; he lived a quiet temperate life, and he had never had syphilis. His present troubles began seven years ago. He was on that occasion taken ill, somewhat suddenly, with sharp pain and tenderness in the region of the gall bladder, vomiting, and jaundice, and he was laid up for several weeks. He was seen by a physician, who diagnosed the case as one of small calculi or gravelly deposit in the gall bladder; and another medical man, who saw him about this time, was of opinion that the gall bladder could be felt enlarged. From this time onward he was subject to similar attacks, which occurred suddenly and at irregular intervals about twice a year. Between the attacks he was in his usual good health. In some of the attacks he was not jaundiced, but, with this exception, they were all much alike, sudden in their onset, slow to pass away, marked by severe pain and tenderness about the region of the gall bladder, with vomiting; and in the later attacks the pain used

to shoot round to the back and up to the right shoulder. In the autumn of last year (1894) he had an attack of unusual severity, which lasted many weeks; his pain was aggravated by obstinate constipation with accumulation of wind in the bowels. On his recovery he went to Worthing, and was under the care of Mr. Collet there. On December 13th he had for the first time a rigor. On the 21st he had another, and again on the 22nd; and on the 24th there were signs, not well marked, of a slight pleural effusion in front immediately above the liver; about this time also he began to be troubled with sweats, which were sometimes very profuse. But, strange to say, the signs of effusion passed away, and so did the attacks of sweating, and during the greater part of January and the first half of February his temperature was about normal, and he seemed once more convalescent. But on February 14th he again had a rigor, with temperature 102° , and in March his temperature was of a marked hectic character, 101° or 102° every night; he was frequently in pain, and was plainly losing ground.

Previous History of Case 2.—The patient, a man aged 50, had served in the army but had never lived abroad. He had, many years ago, had syphilis, and he admitted that he had been given to drink. Two and a-half years ago he had been in the West London Hospital for five weeks; his board had been headed "hepatitis." He suffered on that occasion from pain in the region of the liver, shooting up to the right shoulder; this pain was said to be continuous, not paroxysmal, worse on deep inspiration; he also had pains in the bowels. Shortly before his admission he had been jaundiced. He complained also of pain in his right side, and it was noted that he had some tenderness over the ninth rib, and that there was "a doubtful feeling of fulness" on that side. For three weeks his temperature was of a hectic character, rising to 101° or 102° every night. Then the fever ceased; the pain also ceased, and he left the hospital. For two and a-half years nothing was heard of him. Then he came back, having had a second attack of jaundice, followed by the return of his old pain, and he was admitted into the hospital on May 3rd.

2. *Condition of Case 1 just before Operation*.—This patient, though he did not appear in immediate danger of his life, was very weak and feverish, restless and depressed, suffering from acute lancinating pains not only in the region of the liver, the right side, and the right shoulder, but also up the spine to the back of the head, and down the backs of both thighs to the calves. There was no enlargement of the front of the liver, nor could its edge be felt below the ribs, nor was there any increase of the liver dulness in front. Behind, in the line of the angle of the scapula, there was slight dulness over the lower ribs, from the seventh to the tenth, and the intercostal spaces here felt somewhat firmer than natural. And it is worth noting that when this area was percussed, the patient himself felt a distinct thrill or impulse in the region of the liver. The significance of these signs and of the whole history of the case was pointed out to me by Dr. Douglas Powell, who kindly saw the patient more than once, and made the diagnosis of suppurating hydatid.

Condition of Case 2 just before Operation.—This patient was now desperately ill, having refused operation up to the last moment, and he had taken a great change for the worse in the last twenty-four hours. He was, moreover, in every way a bad patient for operation; he had been given to drink, and though he was only 50, his arteries were atheromatous, and he had marked areus senilis. Worst of all, there were signs that peritonitis had set in. For eight days his temperature had been ranging from 100° to 103° , and had now fallen suddenly. His tongue was dry, his pulse quick and weak; he was jaundiced; he suffered with frequent vomiting and persistent diarrhoea, and was utterly exhausted. His liver, which had been well below the ribs on admission, was now 3½ inches below them in the nipple line, and its vertical measurement in this line was 6½ inches, but the surface thus exposed did not feel tense, nor did it raise the abdominal wall over it to any marked extent. In the mid-axillary line the dulness began at the lower border of the seventh rib. The breath sounds at the base of the lung were normal. His general condition seemed almost hopeless; his face was drawn, his breathing shallow and painful, his abdomen tense and distended. Dr. Ball, who has kindly let me report

Read in the Section of Surgery at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

this case, had in vain urged operation to the patient; he had steadily refused it till it now seemed impossible that he should recover after it.

3. Operation in Case 1.—This was done on March 28th, with the advice and help of Dr. Douglas Powell, Mr. Edgar Willett, and Mr. Meakin. I began by putting in an exploring syringe through the ninth space, just below the angle of the scapula; the needle was thrust straight forward for $\frac{3}{4}$ or 4 inches, and was felt to enter a cavity, and pus was drawn off at once. I left the needle of the syringe *in situ* to serve as a guide, in accordance with Mr. Godlee's teaching, and resected $\frac{3}{4}$ inches of the ninth rib, in the line of the angle of the scapula. It was necessary to resect the rib thus freely, as the subcutaneous fat was of considerable depth, and it was of great importance to have plenty of room to work in. The pleura was freely laid open, and a quantity of air was sucked into the pleural cavity with each inspiration. There were no pleural adhesions, and no fluid in the pleural cavity. The lung was not seen. The diaphragm was very tense, and was pushed up so high that it was almost vertical; it moved in respiration, but not freely. There was a clear space, from half an inch to an inch between it and the chest wall. In accordance with Mr. Godlee's teaching, I stitched the diaphragm to the pleura, so as to shut off the pleural sac, using a strong curved needle on a long handle, and putting in two stitches, one for each edge of the incision through the pleura. The needle must be passed first through the diaphragm, taking firm hold in it, and then through the pleura; it was impossible to pass it the reverse way, as the diaphragm kept moving out of reach. Then I incised the diaphragm between the stitches, punctured the cyst, dilated the opening, laid the cyst freely open, and fastened it in the wound. About a quart of purulent fluid and cysts was let out. The cavity was well washed out, and drained with a very large tube.

Operation in Case 2.—As the liver reached downward for three and a-half inches below the ribs we hoped that we should get at the cyst by an anterior incision. I therefore opened the abdomen through the right rectus muscle. More than half a pint of turbid fluid mixed with lymph escaped from the abdominal cavity. The parietal peritoneum was slightly roughened, the liver itself was smooth, lax, and of the natural shape; it was evidently depressed by some growth in the upper posterior part of it. I explored it in two places to a depth of two or two and a-half inches with an exploring syringe, but nothing came but blood. The punctures kept oozing; this was stopped by putting a fine stitch through each of them. I now made a small incision over the dull area behind, and thrust the exploring syringe well forward through the eighth space in the posterior axillary line, and drew off pus. I left the needle *in situ* to serve as a guide and cleared the anterior incision and resected two inches of the ninth rib in the posterior axillary line. As the bit of rib was being removed we heard a faint whistling of air, as if there were a small wound of the pleura, but this stopped as soon as the bit of rib had been removed. I came straight down on the naked fibres of the diaphragm close to their insertion into the tenth rib and I did not see the pleura at all. I incised the diaphragm, punctured the cyst, and laid it freely open, letting out a large quantity of turbid fluid and cysts. A large tube was put in and the patient was got back to bed with all possible speed as he was very badly collapsed.

4. Result of Operation in Case 1.—This patient did well steadily, after he had once recovered from the shock of the operation. The day after the operation the lung seemed acting well, and no trouble came of the air that had been drawn into the pleural cavity. The pulse varied most, ranging from 68 to 110; the respiration was always between 18 and 22; the temperature only once rose to one degree above normal. The discharge was profuse, sometimes mixed with bile, or with shreds and strips of membrane. The drainage tube was finally left out just four weeks after the operation. When I last heard of him, three weeks ago, he was in excellent health and strength. He had then a very narrow straight sinus about 3 inches long, but nothing came from it, and it gave him no trouble.

Result of Operation in Case 2.—The account of this patient's condition just before operation shows that we had to deal with a case that was already hopeless. At the operation we

found, as we had expected, that acute peritonitis had already set in; he never rallied, and died about 29 hours after the operation. *Post mortem*, a large thick-walled hydatid cyst, 8 or 9 inches in diameter, grew from the upper posterior aspect of the right lobe of the liver. It was still nearly full of cysts of all sizes. No part of its wall could have been reached through the front of the liver. There was peritonitis with effusion, and in the right pleural cavity there was about a pint of sero-purulent fluid with flakes of lymph floating in it. This had evidently been effused some time before the operation.

REMARKS ON THE TWO CASES TAKEN TOGETHER.

First, as regards diagnosis. The first case had been diagnosed seven years ago as a case of disease of the gall bladder. The second case had been diagnosed two years and a-half ago as a case of hepatitis. There were many reasons why a right diagnosis was at first quite impossible. The disease in both cases advanced, not regularly, but by fits and starts; a short, sharp attack of illness was followed by a long period of apparent health. The first patient had many attacks of this character; the second had an interval of two years and a half between his first attack and his second. Again, there was no bulging or tension of the liver in front in either case. In the first patient the liver never came below the ribs to any notable extent, and at the operation could not be felt below the ribs at all. In the second patient it is true that the liver descended far below the ribs, but there was no projection or tension; it just came down as it would in a case of simple enlargement of the liver.

Six things at last showed that the original diagnosis was wrong in each case:

1. The occurrence of rigors.
2. The occurrence of frequent attacks of sweating.
3. Diffusion of the pain beyond its original limits; at first the pain was felt only in the region of the liver; then it radiated to the shoulders; finally, as years went on, it was felt in the spine and along the great sciatic nerves.
4. Increase of pressure upward and backward on the pleura and on the diaphragm, leading to shortness of breath, loss of appetite, and vomiting, and finally revealing itself by slight increase of dulness in the lines of the posterior axillary fold and of the angle of the scapula.
5. The temperature during the last few weeks before operation in each case was that of suppuration. In the first case the temperature rose every night to 101° or 102° ; in the second it ran high, both night and day, for a fortnight.
6. In spite of most careful treatment and nursing both the patients were going steadily down hill, losing flesh and strength and sleep and hope, with a steady increase of fever and of pain.

Next, as regards the operation. I leave out of consideration the attempt made in the second case to reach the disease by an anterior incision. As regards reaching the disease from behind, the important question is this: shall I go through the pleura, and shut it off by stitching the diaphragm to it before opening the cyst, or shall I be able to reach the cyst without opening the pleura? Now, from several observations which were made in the *post mortem* room by Dr. Rislen Russell (to whom I wish to express my gratitude) and by myself it appears that if one opens the tenth space, either in the posterior axillary line or in the line of the angle of the scapula, one would probably, but not certainly, open the pleura. Of course it might be possible to reach a cyst, placed as these were, by making an incision below the tenth rib; but the lower one goes the greater is the risk of getting below the cyst altogether. It seems so far as two cases can prove anything that one should be guided by the indications given by percussion. Where dulness can clearly be made out there the exploring syringe should be put in and thrust well forward. If it draws off pus, then one should go along its track, even though it involves laying the pleura open.

ALCOHOLISM IN FRANCE.—The following statistics by M. Magnan give an idea of the prevalence of alcoholism in the department of the Seine. Among 3740 patients (2072 men and 1668 women) admitted to the Sainte Anne Asylum in 1894, there were 775 suffering from alcoholism; of these, 624 were men and 151 were women.

CASE OF NASAL POLYPI ASSOCIATED WITH TACHYCARDIA,

RELIEVED AFTER REMOVAL OF THE OBSTRUCTION IN THE NOSE.¹

By W. SPENCER WATSON, F.R.C.S. Eng., M.B. Lond.,
Late Surgeon to the Throat Department, Great Northern Central
Hospital.

F. G. R., aged about 35 years, married, and temperate, a clerk in a Government office, consulted me by Dr. Sansom's advice on December 23rd, 1893. He had noticed some obstruction of the nose for about four months, and latterly (for about twelve weeks) the difficulty of breathing through the nose had been much aggravated, especially at night. He had also lately suffered from an uneasy consciousness of rapidity of the heart's beat, not, however, amounting to palpitation nor to stoppage, but sufficiently unpleasant to alarm him and make him anxious.

The pulse-rate, as observed by Dr. Sansom, was 120 per minute, the tachycardia being persistent. There was an area of precordial pain below the nipple and over the site of the left ventricle; no murmurs were heard. There was marked anaemia. He looked ill, being pale and having an anxious expression.

Polypi were easily detected in both nasal fossae, the lower channels of which were not completely blocked, so that nasal breathing was still possible, though with some difficulty.

On December 23rd, 1893, cocaine was applied, and polypi were removed from the right nostril.

On December 24th and 31st further operations were performed on both sides.

On January 11th, 1894, the breath channels were almost clear, but some polypoid were still visible. He expressed himself as much improved in general health since the operation.

Between January 18th and December 13th, 1894, further operations were performed on eleven occasions.

On January 4th, 1894, the patient's nose was perfectly free from obstruction, and he had no cardiac trouble, but slight bronchial catarrh.

On January 15th he was much better; but there was still a small polypoid growth, which was cauterised by pointed electric cautery.

On March 19th he came to report himself. The nasal breathing was quite free; he had passed through the severe winter with comfort, and had had no cardiac trouble nor bronchial catarrh since the last note. He was looking well, and seemed bright and cheerful.

Remarks.—The tachycardia was probably of reflex origin. This symptom is in my experience of intranasal disease, not common; but Dr. Sansom has met with similar cases, and at once recognised the probable connection of the cardiac and nasal trouble in this case. It is important, therefore, that in the absence of cardiac murmurs the search for intranasal disease should never be neglected whenever there is tachycardia with anaemia and precordial pain. The precise mechanism of the reflex irritation is not quite obvious.

A report by the Clinical Research Association, November 20th, 1894, stated that microscopic examination of the specimens removed demonstrated that the gritty, bone-like substance in one of them was cartilage embedded in dense fibrous tissue, and bounded on the one hand by a very vascular layer, and on the other supporting small polypoid growths. Histologically these growths were composed of loose connective tissue covered with nasal mucous membrane. They presented also a few glandular tubules, and some of these were dilated into small cysts.

THE DARTFORD WATER SUPPLY.—A contract for filtering the water supply at this station by the Pasteur system of filtration has been, the *Pioneer* says, concluded with a Calcutta firm.

SAMUEL NOTHARD, of Canteen Street, Teddington, was bitten by a rabid dog, on September 1st, and sent on September 6th to the Pasteur Institute, Paris. He went through a full course of treatment, but on Monday, October 14th, developed marked symptoms of rabies, and died on October 17th.

VOCAL DEFECTS AMONGST SCHOOL BOARD TEACHERS, WITH SPECIAL REFERENCE TO THE OCCURRENCE OF TEACHERS' NODES.¹

By WILLIAM MILLIGAN, M.D.,

Senior Assistant Surgeon, Manchester Institution for Diseases of the Ear; Senior Assistant Physician, Manchester Hospital for Diseases of the Throat; Lecturer upon Diseases of the Ear, Owens College.

HAVING had frequent opportunities during the last few years of studying the effects of prolonged use of the vocal organs amongst school board teachers, I desire to lay before you a few general observations bearing upon the etiology and mode of production of certain pathological conditions affecting the vocal cords at times to such an extent as to prevent the individual from following out his or her occupation. These observations have been mainly confined to the study of changes occurring in the laryngeal cavities of female school board teachers, partly because they have appeared to me to suffer in this respect more frequently than male school board teachers, and partly also because in certain schools female teachers are the more numerous body, and as a consequence come more frequently under observation. The pathological changes encountered appear to bear a direct relation to the length of time during which the individual has taught. For convenience of description the lesions found may be classified as follows:

1. Subacute and chronic laryngeal catarrh affecting mainly the true vocal cords.

2. Chronic catarrhal laryngitis with subsequent paresis of certain laryngeal muscles.

3. Chronic catarrhal laryngitis with a varicose condition of the smaller vessels of the true cords.

4. Chronic catarrhal laryngitis with secondary pachydermia changes, local or generalised.

These various stages may pass almost insensibly from the one to the other, so that when the stage of actual node formation is reached we must recollect that it is in reality the outcome of a gradually progressive series of pathological changes.

The catarrhal laryngitis from which so many teachers suffer appears to be from the commencement of a chronic catarrhal nature. Slow and insidious changes, due to a hyperemic condition of the blood vessels of the true cords, are set up, ending in a gradual hyperplasia of the submucous connective tissues, and followed by paresis of certain laryngeal muscles. These changes may progress somewhat rapidly, and at an early stage minute nodes may appear. Thus M. G., aged 14½, commenced her duties as a pupil teacher at the age of 13 years 3 months. Her general health had never been very good, and at the time of admission to hospital she was found to be distinctly anemic.

Upon examination, the laryngeal mucous membrane was found hyperemic and hypersecretory. Slight paresis of the tensors was present, and upon the edge of the right cord a minute node was seen to be forming. Usually, but not always, the changes are symmetrical. In one case in particular the left vocal cord was found distinctly granular, almost in its entire length, but no departure from the normal was observed upon the right side. The actual position of the nodes seems to vary but little, and in my experience they have been situated upon the edge of the cords at the junction of the anterior with the middle third. Usually they are about the same size, although cases have been seen where one node was distinctly larger than the node upon the opposite cord.

Thus L. S., female, aged 20, had taught as a school board teacher for six years. For three years before applying at hospital her voice had given her trouble, being easily fatigued and at times very husky. She had taught classes of various sizes, but usually the number of pupils ranged from 30 to 50. The school at which she taught was situated in a noisy thoroughfare. The room where her classes met there were three classes in the room was large, and fairly well ventilated.

¹ Read in the Section of Laryngology at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

lated. Her general health had always been good. Upon examination the laryngeal mucous membrane was hyperæmic, and well marked nodes were seen upon the edges of the vocal cords, that upon the left cord being somewhat the larger. Numerous cases such as the above could be cited.

In investigating the causes of these various lesions, certain significant factors appear to me to throw light upon the particular condition which is found. In the first place, the hours during which the teacher is required to teach are, in many instances, somewhat long. Thus it is by no means uncommon for a teacher to have to teach for from five to six hours (Saturday and Sundays excepted) in a large school-room where, perhaps, several other classes are being held at the same time. As a consequence of this the voice has to be raised considerably beyond its normal pitch, with the result that marked vocal fatigue is soon induced. An extra strain being thus put upon the laryngeal structures a hyperæmic condition is set up, resulting as time goes on in secondary changes in the mucous membrane taking place. In addition, in many instances girls assume the duties of pupil teacher at an early age, 13 to 16, before the vocal organs are in a position to stand any undue strain, and just at the age when the first great tax is being put upon the female economy. I have been struck on several occasions by finding that the most aggravated forms of school board laryngitis have occurred amongst girls who began their career as pupil teachers at this early age, and cannot dissociate the *post hoc* *propter hoc*. Again, the fact that in the majority of schools the rooms are large and are occupied by several classes at the same time with the result that the teacher, in order to be properly heard, must raise her voice and keep her voice at a raised pitch, must in the long run have most injurious effects.

The fact also that the school is frequently placed in a main thoroughfare along which there is a constant stream of traffic with consequent noise entails undue vocal exertion, and if the windows of the schoolroom have to be kept open, as so often is the case, to ensure fairly efficient ventilation, it will be easily seen what constant and excessive demands are made upon the vocal apparatus of the individual teacher. The long hours, the close rooms, the constant mental strain, and the general want of outdoor exercise must also be important factors in inducing that condition of anemia so frequently met with amongst female teachers, a condition which, while lowering the general vitality, must react injuriously upon an already weakened vocal apparatus.

I would also like to point out the frequency with which nasal, but more especially post-nasal catarrh, is encountered amongst these teachers, and to suggest that its presence may have something more than a casual relation to the perverted laryngeal condition.

The general effect of these various etiological factors working separately or in a combined manner is, as has already been pointed out, to induce in the first place a hyperæmic condition of the laryngeal mucosa. As a result, slight hypertrophy of the connective tissues ensues with thickening of the vocal cords and consequent imperfect coaptation during phonatory efforts. Should the same predisposing causes act during a prolonged period, a secondary inflammation of the musculature takes place with resulting paresis of various laryngeal muscles. These changes may be readily observed.

Thus F. S., female, aged 16, had taught as pupil teacher for eighteen months previous to applying at the hospital. Her general health had on the whole been good, although when first seen she appeared anæmic and had a venous murmur over the cardiac region. She had taught a class of from forty to sixty children in a room in which three other classes were held at the same time. For the first year she had noticed no apparent defect in her voice, but very shortly afterwards she complained of a marked sense of laryngeal fatigue with an accompanying degree of loss of voice. Upon examination the laryngeal mucous membrane was found to be hyperæmic, the true cords slightly swollen and covered with a small quantity of tenacious mucus. She was advised to rest the voice by taking a complete holiday for two months, and to use a sedative inhalation for five minutes twice daily so as to wash out the larynx as it were with a medicated vapour. At the end of two months she resumed her scholastic duties, and was not seen again for twelve months. When she did

reapply at the hospital, she stated that during the preceding three months the voice had given her a great deal of trouble, that she readily became very husky, that she suffered from a sense of rawness and oppression over the larynx, and that towards evening she became almost aphonic. Upon examination, marked chronic catarrhal laryngitis was found, with paresis of the tensors, and, in addition, the presence of small nodes upon the edges of both cords at the junction of their anterior and middle thirds.

In a few cases marked varicosity of the blood vessels running along one or both cords has been observed, and in one particular case a small angiomatous tumour appeared quite suddenly after a too prolonged use of the voice.

In the majority of cases which have come under my care, both in private and in hospital practice, definite nodes have been seen upon laryngeal examination. These nodes have varied from the size of a pin-point to that of a millet seed; have at times been situated upon one cord, although usually upon both, and have without exception occupied the free edge of the cord at the junction of its anterior and middle thirds. In appearance they have shown an almost pearly-white colour, and usually a small vessel has been traced running from the surface of the cord to the base of the node.

With regard to their actual nature, by some they are regarded purely as the products of an underlying inflammatory process, and are hence called "inflammation nodes." Others look upon their occurrence as the direct result of mechanical irritation due to the effects of prolonged muscular strain.

Fraenkel¹ regards them as being of glandular origin, but Coyne² and Kanthack³ deny the existence of glands towards the free edge of the vocal cords. Stoerk,⁴ on the other hand, finds that the nodules are most frequently formed of connective tissue, of elastic fibres and proliferated epithelial cells, while Türk and Wagner⁵ regard them as related to the condition of chondritis or trachoma of the vocal cords consisting of a localised thickening due to small confluent tumours caused by hypertrophy of the chorion and epithelium. My own observations lead me to the belief that the node is the outcome of a localised inflammatory process, a chondritis; that on account of frequent mechanical irritation and muscular over-strain congestions, hæmorrhages, and serous transudations occur with the result that a hypertrophy of the epithelium and submucous connective tissues takes place. I am inclined also to think that the second node is in some cases at any rate due to the mechanical irritation produced by the first formed node. No doubt in the majority of cases the same causes acting equally upon both cords during the same time and in the same manner, affect both cords equally, but this is not always so. It is not uncommon to find patients suffering from hoarseness and partial loss of voice, who, upon examination, present the clinical picture of a single sessile node at the junction of the anterior with the middle third of the cord, while in other cases one occasionally sees a well-marked node upon one cord with a commencing node upon the other.

Thus E. H., female, aged 26, was seen in consultation on account of huskiness and partial loss of voice. The patient was very fond of music, and having had a good voice was accustomed to sing at times for hours together. After a time the voice became easily fatigued, and this was soon followed by huskiness and inability to take high notes. Upon examination a minute node was seen upon the free border of the right cord at the junction of the anterior with the middle third. The left cord appeared normal, save for a slight congestion of the superficial blood vessels.

Again, M. T., female, aged 23, school board teacher, came to hospital complaining of marked vocal fatigue, accompanied by a considerable degree of hoarseness. She had begun teaching as a pupil teacher when aged 14, and had taught ever since. Upon examination a well-marked node was seen upon the free edge of the right vocal cord, and a smaller node (quite half the size) occupying a corresponding position upon the left cord. The impression formed from observing this

⁵ Klinik der Krankheit des Kehlkopfes. Wien, 1886.

case was that the node upon the left end was probably the outcome of mechanical irritation produced by the larger node upon the right cord.

In the treatment of the above described changes in the laryngeal mucosa it appears to me that almost more is to be expected by way of preventing such conditions from arising than is to be attained by any form of local treatment. In the first instance, I am fully convinced that girls are allowed to undertake the duties of pupil teacher at far too early an age. An intelligent girl, with an aptitude for work, can pass the sixth standard by the time that she is from 13 to 14 years of age, and is then eligible for the post of pupil teacher. Having acquired such a post, she has immediately to tax the resources of her vocal apparatus to such an extent that the organ is unable to stand the strain and consequently breaks down either in whole or in part. Much good could, I think, be done by raising the age at which girls should be allowed to assume the duties of teacher to a time when the component parts of the larynx are in a more stable condition than can possibly be the case at the age of 13 to 14. Then again the vicious system of holding three or four classes in one room, at times with no separation between them but the breadth of a form, at other times separated merely by curtains, should be entirely abolished, and each class be allowed to meet in a separate well-lighted and well-ventilated room. I would also like to suggest at this point the great advisability of having the benches for the pupils placed in tiers, one above the other, so that the teacher, when speaking, would be obliged to speak up to her audience, and so would have to hold the head erect and the neck straight, in this way giving play to the thoracic muscles, an immense advantage to anyone who has to speak for any length of time. In the majority of schools I understand that the benches are ranged one behind the other upon the flat, but in a few recently built schools (I am alluding specially to Manchester schools), a partial system of benches in tiers has been introduced. In those towns where the schools occupy prominent sites in busy and noisy thoroughfares, I think much would be gained by paving the adjoining street or streets with wood or asphalt, in order to reduce the roar of the traffic as much as possible. I feel satisfied that if these precautions were adopted there would be less giving way of teachers' voices, with resulting better general health, and as the natural outcome more spirited and more efficient teaching of the young. In addition a short course of instruction upon the best methods of voice production and voice preservation prior to the teacher undertaking her regular duties would, I feel sure, be attended by much ultimate gain.

Physiological rest to the affected organ is of course of prime importance, but unfortunately this means time and prolonged holiday, which many a teacher cannot secure, partly on account of want of funds and partly for fear of losing her situation should the period of rest require to be somewhat prolonged. In early cases, where, perhaps, the only appreciable changes are congestion and inflammatory thickening of the mucosa, a short period of vocal rest, combined with the local application of weak mineral astringents and the cautious use of steam inhalations, will often produce beneficial results. I have also seen much good attend the nightly application of Lister's eucal, applied over the larynx for from half an hour to an hour at a time.

In cases where peracute conditions of the laryngeal muscles exist, and where, after any suppurative inflammatory condition has been got rid of, the daily application of the continuous current will be found most effectual. In these cases, however, where definite nodes have formed, be they only the size of millet seeds, I must confess to great disappointment from the use of topical applications or in fact from any form of local treatment. The local application of such astringents or caustics as nitrate of silver, chloride of zinc, or of chromic acid is pruned by many. Others prefer the application of solid nitrate of silver, while still others speak favourably of the galvanocautery. Personally I have fought shy of the use of the caustic point for fear of producing such an amount of electrical contraction that the last state of the patient might be worse than the first. In one case, however, in which, with certain misgivings, I did make use of it the result was, on the whole, favourable. At the same time it appears to me to be a method of treatment requiring the

greatest care and nicety. In those cases where the nodes are of such a size as to enable one to use a crush forceps or a fine snare, no better method of treatment can be adopted, but these cases are the exception rather than the rule.

It has been my experience to see a very considerable number of patients suffering from the presence of nodes upon their vocal cords and the difficulties encountered in trying to secure the return of a voice fit again to withstand the strain of teaching have been such that in several instances the patients have been obliged to give up their vocation as teacher and take to some other walk in life. This, after years of special training as a teacher, is necessarily a very serious matter, and if any preventive measures could be adopted to remove, if possible, those factors which appear to predispose to the formation of such pathological changes, great gain would necessarily accrue.

CHORDITIS TUBEROSA.

By ALEXANDER HODGKINSON, M.B.

Physician, Hospital for Consumption and Diseases of the Throat, Manchester; Lecturer on Laryngology, Owens College, Manchester.

WHILST most authors recognise the fact that this disease occurs in those who use the voice excessively, and that the affection is accompanied by a more or less inflamed condition of the cords, there is considerable variation even amongst leading authorities as to the essential nature of the relationship of these conditions as regards the causation of the disease. Whilst some believe that inflammation causes the node, others believe that the node gives rise to the inflammation. The object of my communication is to show that two factors—a swollen condition of the cords and excessive use of the voice—are essential to the production of "teachers' nodes;" also to show the way in which these factors produce the nodes; and shortly to discuss the treatment. The nodes occur on one or both cords at the junction of about the anterior and middle thirds. A depression may take the place of the node at the corresponding point of the other cord. When the cords are swollen they become jammed by the swelling in the anterior commissure for about one-eighth of an inch, so as to be incapable of vibration for this extent of their length. But immediately posterior to this jammed immovable portion, between the immobile part and the freely movable portions of the cords, are portions of swollen cords, which though just in contact are capable of vibrating, but in consequence of this contact friction occurs during vibration of the cord. This friction produces the node. The position may vary within certain limits, with variation in the amount of the swelling. This attrition spot, even before the formation of the node, is indicated by a pure white spot seen during phonation, a spot caused by churning up of the mucus to froth by the vibrating portions of the cords in contact. The same phenomenon, to a less marked degree, may be seen anterior to the processus vocales. This "foam spot" may be taken as an indication of the probable formation of a nodule unless the swelling of the cords disappear or the voice is rested. The reason why a node forms on one or both cords is probably due to the fact that only one or both cords are swollen respectively.

Dr. DELAVAN (New York) called attention to the dire effect on a child's voice of attempted conversation with the deaf, and urged greater care in this direction. He had found treatment of singers' nodes unsatisfactory; whilst rest and local applications would relieve the conditions for awhile, it was apt to recur upon renewed use of the voice. In some cases he had found it very difficult, if not impossible, to eradicate. Operative measures he had never been satisfied to adopt.

Dr. A. BRONNER thought girls suffered more than men, as they were less apt to yield to the necessity of stopping work early enough.

¹ Abstract of a paper read to the Section of Laryngology at the Annual Meeting of the British Medical Association, held in London, July-August, 1894.

A METHOD OF REMOVING NASO-PHARYNGEAL TUMOURS TO PREVENT BLEEDING FROM THE PEDICLE.*

By GEORGE STOKER, M.R.C.P.L., M.R.C.S.Eng.,
Physician, London Throat Hospital.

THE removal of naso-pharyngeal tumours is always accompanied with difficulty to the operator, and often with danger to the patient. The difficulties and dangers are produced and increased by the nature of the operation performed and the occurrence of serious bleeding. The bleeding comes from the pedicle or point of attachment of the tumour. Some operations consist in dividing the palate in order to get at the tumour and secure room for manipulating its removal. Other operations consist in removing portions of the superior maxillary bone with a view of reaching the naso-pharynx from the front. Such operations cannot but be regarded as being most serious, and presenting in themselves greater sources of danger to the patient than the removal of the tumour itself, and are therefore, if possible, to be avoided and only undertaken when no other alternative exists. The method I propose, and which I have practised, is an alternative, and I consider it a safe one as it enables one to control bleeding if it occurs. The steps of the operation are as follows:

1. The patient when anaesthetised is placed in the "head down position" either by hanging the head over the end of the couch or by placing a hard thick pillow underneath the patient's shoulders.
2. A strong whipcord is then threaded in the instrument shown in the appended illustration.

3. The loop is passed up the nostril, preferably the larger one, and then brought down into the mouth between the anterior surface of the tumour and the posterior surface of the soft palate, and then passed backwards behind the tumour and pushed right up to the point of attachment of the pedicle by the forefinger of the operator's left hand, whilst traction is made on the cord with the right hand.

4. The whipcord ligature is then twisted tight by means of the handle through which it is threaded, care being taken that it is not twisted so as to cut, but only to compress the pedicle.

5. The wire *torsateur* or galvano *torsateur* is then passed through the other nostril, and pushed up to within about a quarter of an inch of the whipcord ligature.

6. The pedicle is then cut through with the wire, and if bleeding occurs the pedicle can be further compressed by the whipcord ligature as necessity may arise.

7. The whipcord ligature can be left *in situ* as long as necessary, and when removed it must be very gradually loosened, and the left forefinger of the operator passed into the naso-pharynx when this is being done, in order to prevent the ligature slipping off too quickly, as if bleeding begins it may be necessary to recompress the pedicle, and leave the ligature *in situ* till further healing takes place.

This is the exact method I have employed with great success, and I have much confidence in recommending it.

the patient began to be much worse, and applied for treatment. He was then suffering from great dyspnoea, pain, cough, and dysphagia. The growth had penetrated the larynx externally, and projected externally in a mass larger than an almond. Complete laryngectomy was performed in April, 1892. In the course of the operation, and when the larynx had been partially removed, Dr. Cohen says:

"The epiglottis being healthy, I made an incision through the hyo-epiglottic membrane, and cut the epiglottis square off. The larynx was then tilted forward. Knowing that there has been difficulty in nourishing patients after this operation, I determined to save the entire oesophagus if possible, instead of severing it at the level of the cricoid cartilage, and by careful manipulation I was able to strip the oesophagus and the mucous membrane from the tips of the arytenoid cartilages and larynx down to the base of the first ring of the trachea without perforating it. The larynx, with the first ring of the trachea attached to it, was then severed from the trachea, and the trachea was stitched to the skin in two flaps formed by the sides of the original tracheotomy incision, which had embraced the second and third rings. The soft parts were then brought loosely together with sutures, without any dressing in the pharynx; and a small, soft rubber stomach tube was inserted into the stomach through an opening left in the upper portion of the dressing. This was done, thinking that there might be a necessity to use it for introducing nourishment; but it was found unnecessary, and it did some harm. An hour had been occupied in the whole procedure—anaesthetisation, operation, and dressing. The patient was then put to bed. He was carefully watched. I stayed with him for sixteen hours; and during that time I instructed a number of young men connected with the throat and surgical clinics of the hospital how to take charge of the case. Two members of these staffs were with him constantly for eighty hours. Twice during that time the man would have died had not skilled hands been present to remove mucus from the tracheal tube. It is to the close attention of these young men

The Patient after Operation.

for the first eighty hours, and to the admirable service of our chief surgical resident, Dr. Hager, that this man chiefly owes his life, for the attention after such an operation is far more important in a clinical point of view than the operation itself, all-important as it is. There was a good deal of oozing alongside of the oesophageal tube. On the third night this tube became detached, and we did not reintroduce it. Enemata were used for four or five days, and then gradually food given by the mouth. At each attempt at swallowing a piece of gauze was applied above the tracheal wound, and the parts were pressed close together while the patient swallowed. There was a little trickling for a few days, but this

A CASE OF COMPLETE LARYNGECTOMY.†

By PROFESSOR J. SOLIS COHEN, M.D.,
Philadelphia.

DR. BRAYSON DELAVAN showed on behalf of Professor J. Solis Cohen, D. H., aged 48. The history was that a large papilloma of the larynx had been successfully removed by Lefferts in 1876. There was no recurrence for ten years. Then the growth returned. Various methods of intralaryngeal treatment were employed, with unsatisfactory results. In 1891

* Read in the Section of Laryngology at the Annual Meeting of the British Medical Association, held in London, July-August, 1894.

ceased. It was interesting to watch the œsophagus during swallowing before the external wound contracted. It was easy to see that the œsophagus opened when the man took water. There has been some doubt whether there is a mechanical distension of the mouth of the œsophagus in gluttony, or whether there is some such action of the œsophagus itself. In this case it certainly did open to receive the water. The man has made an uninterrupted recovery. There has been no attempt made to use a voice tube."

Dr. BRAYSON DELAVAN said: Let me call your attention to several points of interest which this case illustrates. The man breathes freely with the aid of a tube. He is able to phonate with sufficient power and volume as to be heard distinctly at a considerable distance. He can even sing, although the latter expression must not be understood as meaning too much. He swallows both liquids and solids with ease, and can perform the act of smoking. He is not subject to any troubles of the bronchial tract, and he enjoys good health, although unable to do any kind of hard work. In the course of the operation the external integument was slightly inverted, with the result that several hair follicles were included. From these a number of hairs have grown, and their presence in the inside of the pharynx has been so annoying that it has been necessary from time to time to remove them. The special advantages of the operation have already been alluded to. They are admirably exemplified in this case, and it is chiefly on account of them that I have brought him from the United States to exhibit him to you.

A CASE OF DISLOCATION OF THE FEMUR ON TO THE PUBES, FRACTURE OF THE NECK, AND REMOVAL OF THE HEAD OF THE BONE.

By GEORGE J. W. FLOWER,
Honorary Surgeon to the Yeovil Hospital.

I was called on the evening of July 4th to see A. H., aged 48, who had been under my care for eight or nine years, suffering from locomotor ataxy. He had managed to get about fairly well with the aid of a stick, but on this particular occasion, in stepping off the pavement to allow some people to pass, had fallen and dislocated his hip, the head of the femur being forced on to the pubes. All immediate attempts at manipulating the bone into place having failed, I asked one of my colleagues to visit the patient with me, for the purpose of administering ether, and otherwise rendering me assistance. The anæsthetic having been given, manipulation was recommenced; when suddenly, as the limb was being rotated, the head of the bone separated with a snap from the shaft, which then assumed its proper axis, leaving the head of the bone under the femoral vessels, so that the femoral artery could be felt pulsating over it. The limb immediately presented a dusky—*I might almost say purple*—hue, from venous congestion, and became cold. It was obvious that the only possible course was to cut down upon and remove the head of the bone; and this was accordingly done by means of an incision of about 5 inches in length, and just to the outer side of the vessels. The anterior crural nerve and the femoral vessels were turned aside, and the head of the bone (see illustrations) was removed with the lion forceps. The incision was closed with chromic gut sutures, dressed with iodoform and double cyanide gauze, and a Desault's splint applied. The wound healed by first intention, and at the end of three weeks I put on a plaster spica, and allowed the patient to get up and walk on crutches. He did remarkably well, the shortening is very slight, certainly not more than an inch or an inch and a-half.

I reported the case and showed the patient at the meeting of the Dorset and Hants Branch on October 10th, 1894, on account of its several peculiarities. A dislocation on to the pubes is rare in itself, but the question as to whether in this instance the neck of the bone was partially fractured by the accident and completely broken by the rotation, or whether the

disease from which the patient suffered had made the bone so friable that it could be fractured by simple rotation, remains undecided. Then, again, the fact of the head of the bone having been left under the femoral vessels and obstructing the circulation of the part constitutes, I think, an accident which has not been hitherto reported. I may say that the bone had the appearance of undergoing some form of degeneration, the layer of compact tissue being remarkably thin.

In support of the theory that the bone was rendered friable by disease and fractured by the rotation, it may be said that in locomotor ataxy the bones have a tendency to atrophic changes, and Dr. Charcot, in 1888, described a peculiar form of disease resembling osteo-arthritis with absence of pain, and often great deformity as occurring in the ataxic, and at the same time mentioned this tendency to atrophy of bone and liability to fracture.

The accompanying illustrations show the naked-eye appearance of the fragment and the plane of its separation from the shaft.

October 24th, 1895.—It is interesting to note that now, fifteen months after the accident and operation, the patient walks as well, if not better, than he did before it happened.

MEMORANDA: MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

A CASE OF DIPHTHERIA TREATED BY ANTITOXIN. The following notes seem to us to be worthy of publication whilst the antitoxic treatment is on its trial.

G. K., aged 8 years, daughter of Dr. Kirk, was found on August 26th, 1895, suffering from a sore throat and enlargement of the submaxillary glands, a high temperature, and a thickly furred tongue. Dr. Kirk at once swabbed out the throat with a strong solution of nitrate of silver, which caused the membrane to separate and to be removed, but it was readily reformed. The following day the throat was swabbed out with liq. ferri perchloridi and glycerine twice a day, and the patient given a saline mixture and 5 grains of antipyrin on the night of August 26th. She took food and nourishment well.

Mr. Berry saw her on the morning of August 28th. The tongue was thickly coated, and on the right tonsil there was a sloughy patch the size of a sixpence, and a second one behind it the size of a pea, with a good deal of tenacious mucus in the naso-pharynx, but the posterior wall of the pharynx appeared free; the application of the iron and glycerine had apparently removed the membrane. The temperature was 102.8° F. It was decided that the antitoxin treatment should be employed, and Dr. Peck, the medical officer of health to the Ormskirk Rural Sanitary Authority, kindly came over in the evening and gave her a dose of antitoxin by injection in the cellular tissue near to the inferior angle of the scapula.

On August 30th Mr. Berry saw her again. She had passed a restless night, but slept towards morning. The mucus in the throat was less tenacious, and she had vomited a quantity

of thick-looking secretion. The slough appeared healthier, and the patient was much brighter. The temperature was 101.6° F. At night the temperature was 101.6° F. The patient keeping better and taking plenty of nourishment, it was decided that no more antitoxin was required. On August 31st the throat was much better, the temperature was 100.8° F. On September 1st she was much better, took food well, and the temperature was 99.4° F. On September 5th the throat was quite well, and the temperature had been normal for three days. Quinine in half-grain doses and tr. ferri perchloridi was the medicine given throughout the case after using the antitoxin.

A couple of swabs from the throat taken on August 31st, were sent by Dr. Kirk to the British Institute of Preventive Medicine for examination, and he received the following report:

The membrane sent by Dr. Kirk, of Huddersfield, has been examined by Mr. Nolan, of this Institute, and the bacillus of diphtheria has been isolated. The case therefore is one of genuine diphtheria. M. ARMAND RUFFEN, Director.

There is no doubt that the early active treatment in the first instance and the use of the antitoxin as soon as it could be obtained had a beneficial effect. The gradual decline of temperature as the throat improved was very marked, but the loosening of the tenacious mucus a few hours after the use of the antitoxin was very characteristic.

W. M. REEVE, F.R.C.S.I.,

Hon. Surgeon-General A. West, Victoria Barracks, Wigan.

J. KIRK, L.R.C.P. (Ed.),
Hindley.

AN EASY METHOD OF REDUCING RECENT DISLOCATION OF THE SHOULDER-JOINT.

Is the beginning of March, 1895, I was summoned to attend a Coolie employed in the Naval Dockyard, on examining whom I found suffering from a subcoracoid dislocation of the left humerus. I at once reduced the dislocation by grasping the elbow of the affected arm in my right hand, pressing two fingers of my left hand on the head of the bone in a direction slightly outwards and upwards, at the same time pressing the elbow upwards, the head of the bone at once shooting back into the joint.

On August 1st, 1895, another Coolie employed in the Naval Dockyard came to me with a subcoracoid dislocation of the left shoulder. By pressing the head of the bone in the opposite direction to that which this injury always takes, and which I need not mention, with two fingers of my left hand, and at the same time bringing the elbow of the affected arm slightly forwards, and pressing it to the side with my right hand, I reduced the dislocation with the greatest ease. I have not seen this method of reducing dislocation of the shoulder-joint described in any of the textbooks. In each case the dislocation was almost instantaneously reduced, and with a very slight amount of pain to the patient. In each case the reduction took place about two hours after receiving the injury. Both patients were well-developed, muscular men. I think this simple way of reducing recent dislocations of the shoulder-joint is well worth a trial before proceeding to the more elaborate methods mentioned in the textbooks; if it succeeds it is sure to cause much less injury to the joint than the method usually adopted. In neither of my cases was there any subsequent pain and inflammation of the shoulder-joints. The first patient resumed work in a month and has had no recurrence of the lesion since; the second patient—though it is only a fortnight since the injury happened to him—says he feels all right, and is surprised because he is not yet allowed to use his arm.

W. HALLAHAN,

Surgeon-Captain A.M.S.

The Surgeon to the Mikado, who dressed the wound of Li-Hung Chang after the attack made upon the Chinese steamship at Simonoseki, has at his request had the Order of the Double Dragon, Third Civil Class, conferred upon him by the Emperor of China.

The Legislature of Wisconsin has appropriated 50,000 dollars (£10,000) as a contingent fund to be used by the Health Board, if necessary, at any time during the next two years, to prevent the introduction of cholera.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

THOMAS BUZZARD, M.D., F.R.C.P., President, in the Chair.

Friday, October 5th, 1895.

INTRODUCTORY ADDRESS.

THE PRESIDENT delivered his introductory address deferred from last meeting. After expressing his thanks for the great honour the Society had conferred upon him by electing him to a post which was unsurpassed, in his estimation, by any that could fall to the lot of a practising physician, he remarked that some of the aspirations which had been expressed at the foundation of the Society, twenty-eight years ago, had not been perhaps altogether fulfilled. The application of drugs and medicaments for the cure or relief of disease—the existence of which appeared to be looked upon as a foregone conclusion—overshadowed everything else in the first President's address, which contained no hint of investigation of disease with a view to its prevention as work to engage the attention of the Society. The last quarter of a century had wrought an extraordinary change, a signal illustration of which was to be found in the revolution brought about as a result of Pasteur's immortal researches extended and applied to surgery by the genius of Lister. The success in the treatment of myxodema, a disease the investigation of which was so largely identified with the Clinical Society, was an example of the application of the scientific method in medicine as striking as anything to be found in the domain of physics. The success in the treatment of vast numbers of cases of paralysis and convulsive disorders which had followed the discovery of their frequent dependence upon syphilis was another example of scientific therapeutics, as contrasted with the tentative application of drugs which was formerly the rule. And so, also, the recognition of the influence of alcohol in the causation of a form of progressive paralysis opened the way at once to success in treating such cases. With our present knowledge of that which was formerly most frequently unsuspected, we could picture to ourselves the numerous cases of this description which, even at the time of the Society's formation, must have gone steadily on to death uninfluenced in any degree by the various drugs and other measures which were employed. How little would here avail the most careful trial and comparison and statistics of the effect of this or that drug! In the absence of the key to the cause of the disease, success in treating it would be impossible. Reference was made to the question of the causation of disease by micro-organisms, and it was remarked that in disease of the nervous system the infective origin of leprosy, tetanus, hydrophobia, and diphtheritic paralysis admitted of no reasonable doubt. He suggested that there was a most interesting field for inquiry as to the possible dependence of many chronic diseases of the nervous system upon a source of infection. Infantile paralysis (acute anterior poliomyelitis) there could be little or no doubt, from the occurrence of many epidemics of the disease, was an infective disorder. It was possible, he thought, that the form of progressive muscular atrophy in which the lesion occupied the same anatomical position would be likewise found to be of infective origin. Insular cerebro-spinal sclerosis, there were strong reasons for believing, owed its origin to some influence of this description. The suggestion that chorea and some forms of epilepsy had an analogous origin was yet but a conjecture, which appeared, however, to be worthy of investigation. As regards such "family" diseases as certain myopathies, and the so-called Friedreich's ataxy, the supposed hereditary element might prove, he thought, to be open to a similar explanation to that which many of us experienced respecting tuberculosis and cancer, and that what appeared to be an inheritance might be, at least in great part, the result of exposure of members of the same family to a local source of infection. The subject was one which must be approached from several sides, especially the clinical, bacteriological, and chemical. He could imagine no more important inquiry, and no society, the members of which were so well qualified to do justice to it as that which he had the honour to address.

Mr. CHRISTOPHER HEATH proposed a vote of thanks to the President for his address; this was seconded by Dr. RADCLIFFE CROCKER, and carried unanimously.

The President returned thanks for the vote, and remarked that the surgical members of the Society would have no more sympathetic listener to their papers than himself.

IMPETIGO CONTAGIOSA GYRATA.

Dr. RADCLIFFE CROCKER read this paper. He said that the eruption was a new form of impetigo contagiosa in this country which had cropped up in the last two years, and that well-marked cases were rare. It was characterised by the formation first of a pink papule the size of a hemp seed with a slight indication of a vesiculation at the apex; this enlarged and formed first a tense and later a flaccid bulla from a quarter to a third of an inch in diameter, with sero-purulent contents; a faint narrow red areola surrounded the bulla. The bulla dried into a thin scab while enlarging at the periphery; within there were still indications of fluid, while beyond that the areola had become pronounced. When the centre cleared, a thin greenish crust on the ragged inner edge enclosed the clear centre and was itself surrounded by a red areola. The largest single lesions were about 1 inch in diameter, but some of them coalesced and formed compound lesions of several square inches in area first, and a gyrated outlined patch was thus produced. In one patient the whole back was covered with these gyrate patches, but in many patients there were only a few lesions. From unruptured bullae pure cultures of *staphylococcus pyogenes aureus* were obtained, and in some cases an ordinary form of impetigo contagiosa was present simultaneously with the gyrate eruption either in the patient or in some other member of the family. The author was not aware that this form of eruption had been previously described except by Dr. Patrick Manson, who had described a pemphigus contagiosus tropicus, and judging from Dr. Manson's description, this other affection above discussed appeared to be identical.

The President asked if the author could suggest any plan of diagnosis other than that by cultivations which would enable one to distinguish this disease from the non-contagious pemphigus often found in cases of disease of the nervous system.

Dr. PATRICK MANSON said that the description given by Dr. Crocker did not coincide with that of pemphigus contagiosus as seen by him in China. His own cases had not such a large surrounding area of redness. In China, too, the disease was entirely confined to the hot period of the year, and was only then epidemic. He had found the application of a solution (1 in 1,000) of perchloride of mercury, and dusting with powdered boracic acid, led to marked improvement and rapid subsidence of the disease. It was a diplococcus, not a staphylococcus, that characterised the Chinese cases. For these reasons, therefore, he thought the cases seen by him differed from the eruption described by the author.

Dr. CROCKER, in reply, said that the diagnosis generally turned on the mode of development of this eruption, and accidental distribution of the lesion, which occurred where one would expect it to be planted by the nails. The bullae were flattened, not tense like those of pemphigus. If one compared the description given by himself of his cases with that by Dr. Manson of the Chinese cases, it would be seen that the points of resemblance were striking. Possibly the two sets of cases might be due to different micro-organisms, as different pathogenic agents often produced morphologically identical symptoms.

PRIMARY SARCOMA OF THE PATELLA.

Mr. R. W. PARKER read the sequel to a case of removal of the patella for primary sarcoma. The patient, a girl, aged 13, was shown to the Society, after the operation nearly seven years ago, as recorded in the *Transactions*, vol. xx, p. 254. The growth was intimately connected with the patella, which was removed. The girl recovered with a stiff joint, and remained well for three years. Then a slight local recurrence took place in the scar, which was excised, after which the girl remained well for a further period of three years. Then some new growth occurred in the lymphatic glands deep in the pelvis. An attempt was made to remove them, but was only partially successful. The girl died after some weeks of exhaustion. At the necropsy masses of glandular new growth were found

deeply seated in the pelvis. There were no secondary deposits in any of the organs, nor in any bone. The original growth was a firm spindle-cell sarcoma.

Mr. HOWARD MARSH said that sarcoma of the patella was a very rare disease. He had seen one case years ago at St. Bartholomew's Hospital. Sir James Paget dissected it all away, and thereby opened the knee joint—a serious thing in those days. The patella was often enlarged in osteo-arthritis and syphilis. He had recently had a case of primary sarcoma of the synovial membrane of the knee joint. The disease had been diagnosed as tuberculosis. It was removed. The patient subsequently returned with pain, when Mr. Marsh thought was due to adhesions after the operation. Under chloroform he bent the joint, and adhesions gave way. The disease had since recurred, and probably amputation of the limb would be necessary.

THE TREATMENT OF ACUTE PLEURAL EFFUSION BY EARLY INCISION.

Dr. ALBERT WILSON (Leytonstone) read a paper on this subject. The experience of three successful cases was given in favour of free incision into the pleural cavity, with drainage, as soon as the effusion was so large that it would not be reabsorbed. It was urged that in empyema the lung might be bound down by adhesions, and compressed so as to be unable to expand again, and a case was quoted to illustrate this. The same occurred in minor degree in pleural effusion if drainage was delayed. A case reported by Dr. Morrison in the *BRITISH MEDICAL JOURNAL* of July 13th, 1895, illustrated this. The first and second cases of pleural effusion were simple, and recovered in about ten days. The effusion was large in the second case (5 pints), and the apex beat was under the nipple. The heart returned to normal position, and the lung expanded within half an hour without distress or shock to the patient. Friction sounds indicated expansion of lymph on the pleural surfaces. On the third day the pleural cavity was shut off by the lung; then it was found some air and fluid was sealed up lower down, so the pleural adhesions were detached to allow of drainage. Two days after the operation there were no abnormal physical signs. This was eleven years ago. The patient died two years afterwards, the result of an accident. Meanwhile she was healthy. The third case, in May, 1895, that of a young lady, was complicated with severe influenza and pneumonia. When the operation was done the patient was almost moribund, being kept alive by constant oxygen inhalations and erythraemic injections. Within forty-eight hours the lung had completely expanded. On the fourth day the lung closed the wound; about 6 pints of fluid had been removed from the right side. A week later she was very ill from the pneumonia on the opposite (left) side. A fortnight afterwards the right side was normal. For some weeks the temperature kept rising at night, and she seemed in a rapid decline. So she went to Margate, where she regained the power of walking. In August Dr. Nichols reopened the incision, and about 4 ounces of sweet pus escaped; possibly the lung had closed the wound too soon, hence the great importance of always detaching the lung and draining the lower part. Incision was between the ninth and tenth ribs, in the post-axillary line. Five months after the operation the cavity would hold 4 or 5 ounces of fluid, and reached about 2 inches all round the wound. The temperature kept up, and the case looked very unfavourable, like general tuberculosis. It was found that drainage was imperfect; that always about 2 ounces of pus were retained, and by inserting a small india-rubber drainage tube downwards this part was kept empty. Thus the temperature at once fell to normal, and kept so, until finally the cavity was closed and the wound healed in January, 1896, nine months after the operation.

Dr. S. WEST was surprised that incision was recommended for these cases, seeing that treatment by paracentesis was very successful. By incision a simple serous effusion was usually converted into an empyema, which, if not very grave in children, was certainly serious in adults. The lung expanded well after paracentesis, unless operation were long delayed. It was interesting to hear that the lung expanded so soon after incision, this was contrary to the usual teaching. He had recently published the case of a lady who had had a pleuritic effusion for eighteen months, and was almost

moribund when first seen. Paracentesis frequently repeated so much improved the patient that incision could be performed. In that case, notwithstanding the length of time during which the disease had lasted, the lung completely expanded after incision, and eventually recovery was complete. One should, however, be careful not to operate upon an adult by incision unless compelled by the obduracy of the case to other milder plans of treatment.

Mr. HOWARD MARSH agreed with the author's suggestion, because it was in agreement with the practice pursued for the cure of effusions in other parts of the body. For acute serous effusion into joints, acute hydrocele, and acute periostitis, with effusion and high temperatures, a free incision was made, and the cavity washed out, with the result that in ten or fourteen days the patient quite recovered. The same treatment was also adopted for acute effusion into the abdomen. He ventured to prophesy that the paper would not only draw attention to the treatment of this disease, but would have marked influence on practice in the future.

Dr. S. WUER suggested caution when dealing with the pleura surgically. Caution was then necessary far more than when the peritoneum was concerned. There were cavities and cavities, and all could not be treated in the same manner with impunity.

Dr. WILSON, in reply, said that all his three patients were in a bad way when the operation was done. He thought he could not give enough relief to the tension by aspiration; incision took away all the tension. Further, he made his incision as low down and as far back as possible, in order that, whether the patient were lying or sitting, the drainage from the chest might be uninterrupted.

MEDICAL SOCIETY OF LONDON.

Monday, October 28th, 1895.

Sir J. CRICHTON BROWNE, M.D., F.R.S., President, in the Chair.

CASES OF INTESTINAL RESECTION AND INTESTINAL EXCLUSION.

Mr. C. B. KEETLEY read notes of three cases of intestinal resection and intestinal exclusion. Case 1. The patient, a girl, aged 17, had been ill for a year, her illness having commenced after exposure to damp cold. She was in a hectic condition, and passed pus *per rectum*. There was a large abscess in the lower abdominal wall, which he opened, and subsequently the wound partially closed, the lower part, from which a fistulous tract led to the rectum, being packed with gauze. A few days later a fistula opened into the small intestine. Some time after he performed laparotomy, and the small intestine proximal to the fistula was divided and united end to end by Maunsell's method to the gut distal to the fistula, which led to the rectum and skin respectively. The patient is actually in good health, and wears a colotomy truss over the fistulous opening in the abdominal wall. Case 2 was that of a girl, aged 15, who presented two tumours in the abdomen below, and to the right of the umbilicus. The lower tumour was fixed, and the upper one movable. She was much emaciated, and was greatly troubled by persistent vomiting. There was also hæmorrhage *per rectum*. He made an incision over the lower swelling, and came upon the ascending colon, within which he could feel a tumour. He opened it, and found that the interior of the gut was occupied by a growth involving the origin of the ileo-cæcal valve. He resected it, cutting off the tumour flush with the cæcum, and invaginated it into the cæcum by Maunsell's method, except that the peritoneum was not included. Six weeks later he made an attempt to remove the enlarged glands, and in doing so he divided the mesocolon. This led to sloughing of the ascending colon and the formation of a faecal fistula. The patient ultimately succumbed to obstruction due to recurrence. Case 3 was that of a middle-aged man, with a large tumour in the left side of the abdomen, which was readily movable. He opened the abdomen through the left semilunar line, and found that the growth surrounded the splenic flexure, including the whole of the omentum and a piece of the small intestine. The operation of removing the tumour took him 3½ hours, and the patient died twenty-four hours later.

A SERIES OF CASES OF INTESTINAL RESECTION.

Mr. HERBERT ALLINGHAM said he had operated on 10 cases, in all, of which number 6 recovered and 4 died. In 4 of the successful cases the intestines were empty prior to resection, whereas in all the 4 fatal cases the intestines were distended when the stricture was resected. This seemed to show that distension of the intestines at the time of resection enormously increased the risk attending the operation. The explanation of this circumstance was probably that large quantities of faeces pressed down towards the site of union, and constantly disturbed it by the peristaltic waves they set up. Moreover, the patient under these circumstances is, so to speak, poisoned by the faecal accumulation, thus hindering union of the divided ends of intestine. In large intestine cases faeces may block the bobbin and even tear it away. It follows that large intestines must not be resected when the gut above the stricture is distended by faeces. Stricture of the small intestine might be resected even when distended, because the faeces are usually liquid. When the intestines are distended the gut just above the stricture should be fixed to the abdominal wall; in fact, a colotomy should be performed, by which means the intestine can be thoroughly emptied. Later on the colotomy wound should be resected, and an end-to-end anastomosis done. In some cases it is possible to bring the stricture piece out through the abdominal wall, and in such case it should be fixed there, and the gut above it opened. Later on the stricture piece of gut can be resected, and the end-to-end anastomosis done. Some form of bobbin or button was, he thought, absolutely necessary in intestinal cases of resection or anastomosis.

After some remarks by the PRESIDENT, the SECRETARY read a note from Mr. Mayo Robson, who explained his use of the decalcified bone bobbin in intestinal operations. He said he had employed it in a great number and variety of cases, and it had always appeared to him to act as a support to the sutures, in fact as a splint to the sutured bowel. He claimed for it that it prevented tension, with the consequent risk of sloughing, and protected the joined mucous surface against contamination and cicatricial contraction. The raised ends of the bobbin prevented slipping, and as it underwent absorption, no foreign body was left to set up irritation in the bowel. Its lightness prevented any dragging.

Mr. BIDWELL called attention to a method of intestinal suture which had not been mentioned, namely, that introduced by Halstead of Baltimore, who had pointed out that the serous and muscular coats were not by themselves strong enough to resist the traction of sutures. He therefore advocated the inclusion of the submucosa in the suture. In all his own cases of intestinal suture he had used this suture in combination with others. He had had one very successful case by Maunsell's method. In his case, as in one of Mr. Keetley's, there was some faecal discharge from the wound, and this led him to think that Maunsell's method was not altogether reliable. The addition of a further row of sutures would make the operation too long, and for this reason he preferred to use Mayo Robson's bobbin. He added that experience was a very important factor, and each surgeon would probably be most successful with the particular form of suture with which he was familiar.

Mr. BRUCE CLARKE urged that no absolute rule could be laid down as to the best method of uniting any two pieces of intestines; indeed, the great difficulty in his experience had always been to ascertain exactly what was the matter. Two or three years ago he had shown at the Clinical Society a boy with a big hernia, for which he had already been operated upon without benefit, so that when first seen a large portion of his large and small intestines, together with the cæcum, was outside the abdomen. It took him three-quarters of an hour to make out the exact condition of affairs, and finally he decided to resect a large portion of intestine, as this seemed to be the only way of putting things right. He therefore took away the cæcum, with several inches of large and small intestine, uniting the ends by suture. The result was perfectly successful, and in six weeks the boy was up and about. If one clamped the gut the mucous membrane protruded and could easily be joined end to end by a continuous suture, carrying the last stitch into the interior of the gut. Then the two ends of the peritoneal and muscular

coats were united so as to bring a large portion of their surfaces into contact. Maunsell's plan of doing this had proved quite satisfactory. He had employed this method of suturing in a couple of cases of gastro-enterostomy, but of course these were not cases in which one expected the patients to survive long. There must, however, be more than one row of sutures. The objections to the use of the bobbin were that it allowed of leakage, and he knew personally of two cases in which the bobbin had caused death by setting up perforation. He believed this had occurred in several other cases. A few instances of this kind would, he urged, be sufficient to prove that they had not yet devised a perfectly satisfactory method of suturing intestine. He did not think the bobbin or button should become the routine treatment in all intestinal cases.

Mr. Lockwood said that all surgeons who had had to deal with these cases would probably confirm what Mr. Allingham had said as to the circumstances under which resection ought not to be done. Circumstances must determine what should then be done. His own experience in this direction had not been large. He had twice had an opportunity of resecting and suturing intestine, and had employed the method described by Mr. Bruce Clarke. One was successful, but an intussusception case died of peritonitis. He declined to admit that the use of bobbins, etc., was necessary in resection of the small intestine, but he admitted that the large intestine was more tolerant of foreign bodies. From the cases he had seen he had acquired a strong bias against the use of mechanical contrivances in the surgery of the intestine. Mr. Allingham's results, he pointed out, were not more satisfactory than similar operations performed on gangrenous gut in hernia under much more adverse conditions; in other words, he had not shown that preponderating measure of success in favour of their use which alone would warrant their use becoming a matter of routine. He added that Mr. Mayo Robson's paper lost much of its value because he spoke in general terms and did not give figures.

Mr. HICKEY, jun., mentioned, with regard to the risk of electrical contraction after resection of small intestine, the case of a patient on whom three years ago he resected 5 inches of small intestine which was gangrenous in a femoral hernia, who was now in the best of health. He used the continuous suture for the mucous membrane, with as many interrupted sutures as could conveniently be inserted. Such a case was satisfactory enough, but he had had three other cases of the same kind, all of which proved fatal.

Mr. STANMORE BISHOP said that from his comparatively small experience of these operations he concluded that the button presented serious drawbacks; he alluded in particular to the holes in the side of the button, which, when the gut was pressed against them by the fingers, were very apt to cut through the walls. He was having some made with the metal turned in so as not to present a cutting edge. He thought that Jessett's bobbin presented certain advantages over that invented by Mayo Robson. He pointed out that celerity did not possess the importance which some attached to it. He had never seen a case of gangrenous gut in hernia in which he had thought it safe to unite the ends of the gut at once. The reunion therefore became a secondary operation in which celerity was not a matter of the first importance.

Mr. KENTLEY, in reply, agreed that speed was of less importance than doing the work properly. It was much more important to keep the patient warm and to avoid loss of blood than to hurry over the concluding steps of the operation. He remarked that temporary fecal fistulae seemed to follow every method of operating, and he suggested that in many instances the escape of fecal matter took place previously to the operation. He added that silk sutures might also act as intestinal irritants when free in the gut.

Mr. ALLINGHAM, in reply, reiterated his confidence in the use of the bobbin, especially as it underwent absorption, and could not cause obstruction or irritation.

SCARLET FEVER EPIDEMIC IN EDINBURGH.—One hundred and seventeen cases of scarlet fever were reported in Edinburgh last week, as against 87 in the preceding week, with 2 deaths for this week, and 3 in the preceding week.

BRITISH GYNÆCOLOGICAL SOCIETY.

CLEMENT GODSON, M.D., President, in the Chair.

Thursday, October 10th, 1895.

SPECIMENS.

MR. E. TENISON COLLINS (Cardiff) showed a very large Spleen removed *post mortem*. Before operation it was thought to be an ovarian tumour; abdominal section showed its true nature. The medical attendant who was present would not sanction its removal, so the abdomen was closed without proceeding further. The patient, however, died the same evening from shock. No hemorrhage was found at the necropsy. Dr. HAYWOOD SMITH had lately had a case sent to him as ovarian. Examination showed it to be spleen. He asked Mr. Bland Sutton to see it with him. Mr. Sutton advised removal, and performed the operation. The patient made a good recovery. Mr. H. B. GARDNER and Mr. J. W. TAYLOR spoke on the subject, and Mr. COLLINS replied.—Mr. J. W. TAYLOR (Birmingham) showed a large Uterine Myoma removed by abdominal pan-hysterectomy. Operation was urgently required on account of hemorrhage. The shape of the tumour rendered the use of the clamp impossible or dangerous, and hysterectomy would have been useless. The patient did well, and was discharged three weeks after operation.—Mr. R. H. HODGSON showed a specimen of a large and partially solid Ovarian Tumour. The evacuated fluid measured 3 quarts, and the remaining solids 4 lbs. The patient made a good recovery.

THE LATE DR. THOMAS KEITH.

The PRESIDENT announced the death on the previous day of Dr. Thomas Keith, a distinguished Honorary Fellow of the Society. It was an irreparable loss both to the Society and to the world at large. He asked the Fellows to pass a vote of condolence with the family of Dr. Keith in their sad bereavement.

Dr. ROBERT BARNES and Dr. BANTOCK supported the President's motion in sympathetic terms, and the vote was passed unanimously.

A NEW METHOD OF PERFORMING ABDOMINAL HYSTERECTOMY, WITH FIVE SUCCESSFUL CASES.

Mr. BOWREMAN JESSETT read this paper. He pointed out that the methods of performing the operation might be divided into three classes: (1) Extraperitoneal method of dealing with the stump by the use of Koerber's clamp; (2) the subperitoneal method of dealing with the stump after removal of the tumour; (3) total extirpation. The objections to the extraperitoneal and subperitoneal methods were discussed. By total extirpation of the whole organ all these objections were overcome, and the author submitted certain operative details which he had carried into practice with the most satisfactory results. Hitherto, operators after removal of the entire uterus with its tumour had laced or stitched the two peritoneal surfaces of the flaps together across the pelvis, thereby restoring the floor of the abdominal cavity. Difficulty hitherto had been experienced in opening up the roof of the vagina, some accomplishing this *per vaginam*, others by having an assistant's finger passed into the vagina. To overcome this difficulty, Mr. Jessett had had a special speculum made, 2 inches long, which an assistant passed into the vagina when the tumour was delivered through the abdominal wound; by having this instrument pushed well home, the roof of the vagina was put upon the stretch, and it was easy after the anterior and posterior flaps were reflected from the tumour to cut down upon the ends of the ligaments before and behind, and then to ligature the uterine arteries on each side; by dividing the tissues between these ligatures and the cervix, the uterus and tumour were lifted out. By lacing the flaps across there was a large raw surface left which would, or might be, a source of septic trouble afterwards. To overcome this he proposed that long loops of silk, some four to six in number, should be passed through these flaps at their edge, so that the knot was made to come out through the speculum in the vagina by catching the loop in a specially made instrument. When all these loops were passed they were drawn taut, and the peritoneal flaps were in this way everted, and doubled upon themselves into the vaginal roof. The vagina was then packed with strips of iodoform gauze, the speculum withdrawn, and the abdominal

wound closed. All the patients on whom Mr. Jessett had performed this operation had convalesced easily and well; in fact, just as after an ordinary ovariectomy or vaginal hysterectomy. He read short notes of five cases on whom he had operated successfully by this plan. The chief points in the operation were: (1) The use of the long speculum passed up the vagina, by means of which the uterus is somewhat lifted up and the roof of the vagina put on the stretch, which enables the operator to cut with precision into the vagina from above. (2) The treatment of the peritoneal flap; by everting and drawing these down through the vagina, the two peritoneal surfaces are brought into accurate apposition, and, by being doubled on themselves, raw surface is apposed to raw surface, and also free drainage is established at the lowest point of the abdominal cavity, through the vagina if required. (3) The flaps being drawn down in this fashion form a plug to the roof of the vagina, and the floor of the pelvic cavity is much firmer than if the peritoneum is simply laced across; moreover, by this method a large raw area is left which is much more likely to cause suppuration. (4) By removing the whole uterus in this manner there is very little hemorrhage, and no need for the use of elastic ligatures or other means for constricting the neck of the tumour. (5) The patients suffer no more pain or inconvenience after the operation than after an ordinary ovariectomy. There is no dragging on the stump, and the abdominal wound is not dragged in afterwards as in those cases which have been treated by the *serre-naud*.

The President thanked Mr. Jessett in the name of the Society for his valuable and interesting paper.

Dr. PURCELL said the chief difference between Mr. Jessett's method and that of Martin, of Berlin, was that the former opened the vagina from above whilst Martin worked from below. He called attention to the great advantages of Trendelenburg's position in this operation.

Dr. HEYWOOD SMITH asked Mr. Jessett whether an ordinary glass speculum would not answer as well as the special one as a guide for opening into the vagina, and also what was the special advantage of the drainage tube in these cases.

Mr. TAYLOR expressed his indebtedness to Mr. Jessett for the work he had done. It seemed to him, however, that no one method could be of general application. For instance, there were cases where the inversion of the broad ligaments would answer as well as the formation of flaps. Dr. Purcell was mistaken in supposing that Martin always adopted one method.

Dr. BANTOCK said the operation would in future rest between extraperitoneal treatment of the stump and total extirpation.

After some remarks by Dr. LEITH NAPIER, Mr. JESSETT replied, and then demonstrated upon the phantom the successive steps of the operation.

HARVEIAN SOCIETY OF LONDON.

Sir JOHN WILLIAMS, Bart., M.D., President, in the Chair.

Thursday, October 17th, 1895.

THE CLIMATE OF EGYPT.

Dr. E. SYMES THOMPSON read a paper on this subject. Discussing the advantages and the dangers of the various routes, he said the short sea passage and the long railway journey were often more fatiguing than the long sea route. Invalids should land at Alexandria, the night landing in the Canal was always dangerous. A short stay at Ramieh, both before and after the journey up the Nile might be made by those who left England in October, and returned in May. The sulphur baths of Helouan, fifteen miles south of Cairo, were useful to those unequal to the fatigues and excitement of the capital. The Mena House Hotel, on the edge of the Desert, close to the Great Pyramid, afforded a sunny haven for persons unable to ascend the Nile. It was not usual to leave Cairo, whether in dahabieh, steamer or railway, before December. Luxor and Assouan were very warm in November, January and February being the best months. In mid-February the temperature at Assouan rose to 100° in the shade, and the same temperature was recorded a week later at Luxor. In January the winds at night were very cold on the river, and the chill at sundown was dangerous to invalids, who must studiously keep under cover. The extensive alluvial plain around Luxor made it less dry

than the desert. Assouan was free from alluvium, and therefore drier, but the wind was apt to be strong. The dangers of life on a dahabieh must be carefully avoided, and the "post steamer" was often found better suited to delicate people. The unbroken sunshine was remarkable; the sun was practically never hidden by cloud. The hotels at Luxor and Assouan were commended. The maladies apt to occur in Egypt were described, and the diseases in the treatment of which the Nile was of service were considered in detail. The soothing influence of the warm dry air was of value in bronchial affections with emphysema, in cases of quiescent phthisis in all stages, especially where the lung affection was of pneumonic, broncho-pneumonic, or pleuritic origin, and particularly where such disorders were consequent on influenza, measles, or enteric fever. Disorders of the nasal, pharyngeal, and Eustachian membranes formed a considerable proportion of the cases treated with benefit in Egypt. Consideration was given to the influence exerted on the gastro-intestinal mucous membrane; chronic dysentery and allied affections should not be sent to Cairo, but chronic forms of digestive disorders benefited at Assouan. Hypochondriacal, hysterical and neurasthenic affections, and conditions of mental strain and nervous breakdown were among the cases most favourably influenced; and every year proved the value of the climate in chronic renal disease, whether of calculous or gouty origin, conditions of deterioration and even degeneration of cardiac, cerebral, or renal tissue were favourably influenced by the sunshine and by the restful life in the dry air. The electrical condition of the desert air tended to interfere with natural sleep in healthy persons, but those previously troubled with insomnia gained ground. In conclusion a comparison was drawn between Egypt, the Alps, the Riviera, the Canaries, and the Cape.

Dr. JAILLAND said Assouan had the best climate in Egypt. The cold weather was short there; it was clean, and did not suffer by the inundations.

Dr. CANNY recommended Luxor; the air was driest there. He thought that patients might go to Egypt about the 10th of November—a date earlier than Dr. Thompson counselled.

Dr. SQUIRE, Dr. CHAPMAN, and Dr. WHARRY also spoke; and some remarks by the President terminated the proceedings.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.

A. W. MAYO ROBINSON, F.R.C.S., President, in the Chair.

Friday, October 18th, 1895.

PRESIDENT'S ADDRESS.

THE PRESIDENT delivered an address on the Surgery of To-day as compared with that of Twenty-five Years Ago, illustrated by the work in the General Infirmary at Leeds.

SYMPHYSECTOMY.

Dr. BRAITHWAITE read notes of a case in which he had performed symphysectomy.

SPLENIC LEUKÆMIA FOLLOWING A BLOW ON THE ABDOMEN.

Dr. CHURTON showed an ironworker, aged 28, whose spleen filled the greater part of the left abdomen and extended beyond the middle line. Red blood cells diminished in number; leucocytes, 1 in 10. Patient looks well; face and lips red, eyes bright, movements brisk, but he is unfit for heavy work (tachypnoea). Family healthy. No illness until this, though careless in food and drink, and has lived in a very damp house and was often wet at work. In 1887 he was kicked in abdomen rather severely, but not disabled. In 1892 a piece of steel weighing 2 lbs. flew off a mass of steel struck by a hammer of 85 tons impact, and travelling in an upward direction from 2 feet above the ground struck him at 8 yards' distance on the left abdomen, about 2 inches from the median line and just above the umbilical horizontal line. The shock may thus have been directed through the colon and spleen, injuring both. He fell violently, but resumed work after three hours. The skin was deeply bruised for two or three weeks; diameter of bruise about 3 inches. Eight or nine months after the blow he began to feel weak; three months later the spleen was found to be enlarged; gradually quick-

ness of breathing came on; he left his work in March last. When first discovered two years ago the spleen was about half its present size; probably, therefore, it had taken one year to attain that size; it seemed possible that after the blow micro-organisms from within had traversed the damaged intestine and invaded the similarly damaged spleen.

THE RELATION OF INFLUENZA TO DISEASES INCIDENTAL TO THE SEASONS.

Dr. BAMPTON (Ilkley) submitted as a rational explanation of the bewildering and chameleon-like behaviour of influenza in different seasons, and in the same individual, the following propositions: 1. That we recognise a pure type of influenza. 2. That we meet with influenza *plus* the disease peculiar to the time of the year, for example, influenza *plus* bronchitis, influenza *plus* follicular tonsillitis, influenza *plus* summer diarrhoea. We have then to deal with compound diseases. 3. We may meet with two specific epidemic diseases running concurrently, for example, mumps *plus* influenza. We then have to deal with a dual disease, each modifying the other. 4. We recognise the lowering of the resisting power during an attack of influenza, bringing into evidence the disease diathetic to the individual, and *vice versa*. We then again have to deal with duality in disease. 5. The modern explanation of the classic clinical saying "that in times of epidemics all diseases are apt to assume an asthenic type" is that at such times we have the specific epidemic germ grafted on the ordinary disease. The ordinary disease has added to it all the potentialities for evil of the specific germ of the disease then epidemic. Recognition of this has an important bearing upon rational and successful treatment.

EXCISION OF LARYNX.

Mr. WARD read a paper on excision of the larynx illustrated by cases in which he had performed the operation.

CARD SPECIMENS.

Dr. ADOLPH BRONNER (Bradford): Lower Turbinate Bones removed for Nasal Obstruction.—Dr. TRIVELYAN: A Becker's Microtome.—Dr. BARBS: Spastic Paraplegia, Pseudo-hypertrophic Paralysis, case of Athetosis.—The PRESIDENT: Case of Gastrostomy, with Sphincter formed by the Rectus Muscle; Myomata Uteri removed *per Vaginum*; Multiple Fibroids removed by Abdominal Hysterectomy with a new treatment of the Pedicle.—Mr. LITTLEWOOD showed a man, aged 69, on whom he had performed suprapubic Prostatectomy on August 22nd, 1895, removing 3½ of prostate. Patient had complete retention with foul urine before the operation; now the urine is clear, and passed every three or four hours during the day and once or twice during the night. Mr. Littlewood also showed a specimen of Malignant Disease of the Cervix Uteri removed by Vaginal Hysterectomy. The broad ligaments were very wide, as there was a hydrosalpinx on one side and a small ovarian cyst on the other; these were removed, the patient making a good recovery.

MIDLAND MEDICAL SOCIETY.

T. EDGAR UNDERHILL, M.D., in the Chair.

Wednesday, October 29th, 1895.

THYROID TUMOUR.

Dr. GAMER showed a man, aged 20, who had had a thyroid tumour the size of a large orange, and causing difficulty in breathing for the past two months. Operation on September 12th, 1895. Both superior thyroid and right inferior thyroid arteries tied. Two small processes from upper part of the gland and a process at lower part, into which left inferior thyroid artery entered left in position. Complete relief of symptoms.

THE LUNGS IN ACUTE PNEUMONIA.

Dr. FOXWELL showed the lungs of a man dead of acute pneumonia. The interest lay in the great thickness of the visceral pleura over the greater part of each lung. The thickening was entirely fibrous, and on the surface lay recent lymph. The parietal pleura were not thickened, and adhered to the visceral only by slight recent inflammatory bands. The illness began with diarrhoea, followed in 8 days by stabbing pains in the chest. Widespread moist friction sounds were first heard, the pneumonic signs appearing

later and very gradually, and never amounting to marked dulness or intense tubular breathing. The pneumonia crept over the greater part of both lungs. The presence of friction and absence of flatness in the percussion note prevented recognition of the old thickened pleura. The peculiarity of the dulness and breath sounds were considered as probably due to the partial distension of both chest-wall and lung, owing to the restraining pleura. The cause of the thickening was doubtful. No history of alcohol or syphilis obtained. When a child, patient had had rheumatic fever twice, but the heart was healthy. Still, one or both of these attacks may have been accompanied by pleuro pneumonia, with the resulting slow fibroid growth, resembling scar tissue. The case showed well the great difficulty sometimes arising in diagnosing thickened pleura in acute pneumonia, and therefore the great value of a knowledge of the previous state of a patient in making a prognosis.

SPECIMENS.

Dr. SHORT showed a Portion of Intestine from a case of Enteric Fever. The Peyer's patches were unusually large, with a deep and extensive ulceration. Tremor of the hands had been a marked symptom throughout. Towards the end of the third week of her illness the girl, who was subject to epilepsy, had a severe fit. After this the pulse rapidly failed, and she died in about twenty-four hours. Dr. Short also showed the Liver, Stomach, and Pancreas from a woman aged 64. The stomach was divided into two cavities by an indurated cicatricial band, which appeared to be secondary to a large transverse ulceration. There were several hard nodules in the pancreas and neighbouring glands, strongly suggesting a malignant origin. The liver showed a large abscess towards the posterior part and several smaller ones in various parts of the gland; whilst scattered all over it were numerous soft hæmorrhagic foci, obviously rapidly breaking down. Nothing was found elsewhere to suggest a pyæmic origin. The marked feature of the case was the latency of the symptoms up to a few days before death.—Dr. MARRIS showed a specimen of Intrapericardial Aneurysm of the Aorta with Chronic Adhesive Pericarditis.

UMBILICAL GROWTH.

Mr. HEATON showed a growth removed from the umbilicus of a boy aged 4½. The child was brought with a history that when he strained he "passed water from his navel." On making him cry a small jet of a clear yellow fluid ran from the umbilicus. A fine probe passed down a fistula at the navel downwards and backwards for 3½ inches. The fluid was clear, light yellow, had a peculiar soapy feel, and was strongly alkaline, in fact, chemically resembled succus entericus. A large thick-walled pear-shaped sac found passing downwards and backwards, and adherent by a band of fibrous tissue to the small intestine. Sac partially excised in September, 1893. In August, 1895, the remaining part of sac was removed, and showed on microscopic examination the structure of small intestine. The vitello-intestinal duct forming the direct communication between the intestines and the yolk sac had been only partially obliterated. The end nearest the intestine was represented by a fibrous cord. Its outer half opened at the umbilicus, and became distended by secretion into a thick-walled muscular sac.

AMPUTATION OF ENTIRE UPPER EXTREMITY.

Mr. CHAVASSE read notes of a case and exhibited a male adult upon whom a primary amputation of the entire upper extremity had been performed for a machinery accident in May last. After the initial shock had been overcome, recovery was rapid and healing complete in a month.

CLINICAL SOCIETY OF MANCHESTER.

S. BUCKLEY, M.D., President, in the Chair.

Tuesday, October 16th, 1895.

SENILE BRADYCARDIA.

Dr. WILKINSON showed a case of senile bradycardia. The patient was a man, aged 62, who had been under observation at the Manchester Infirmary out-patient department for many months. He had double annular senilis, atheromatous radials, pulse full (large excursion with sphygmograph).

tension average; rate 32 to 38, in recumbency 26. When first seen there was absolute suppression of the alternate beat. Now as a rule two heart beats were heard for each pulse beat, some of the secondary beats being palpable and seen in the sphygmogram. At times the stethoscope revealed a first sound coincident with pulse wave, a pause, a louder first sound, a second sound, and then pause. The sounds and impulse were usually weak and the heart itself somewhat dilated. The sphygmogram was contrasted with one taken from a case of true bradycardia with epilepsy. The latter tracing exactly reproduced the one given by Dr. Balfour in his work on *The Senile Heart*. The patient had also an enlarged liver, uniform, painless, and probably fatty; in addition, failure of memory for recent events and frequent attacks of loss of consciousness for the last eight or nine years. The attacks never occurred by night nor when sitting, only on exertion; they lasted five minutes. The preliminary was more akin to vertigo than true faintness, and he always fell backwards, to which fact his head testified. There was no cold sweat, no biting of the tongue, no frothing at the mouth, and he said no spasm; loss of consciousness was complete. He had never been seen in a fit, and the attacks under treatment had very materially diminished in frequency. The combination found effectual was the perchloride of iron with liq. strychnine.

ALCOHOLISM AND TUBERCULOSIS.

Dr. KELYNACK read a short paper on the occurrence of pulmonary tuberculosis in the subjects of alcoholic neuritis, based upon a pathological investigation of eight fatal cases, in seven of which there was more or less well-marked tubercle of the lung.

ENCYSTED VESICAL CALCULI.

Mr. SOUTHAM mentioned the case of a man, aged 53, on whom suprapubic lithotomy had twice been performed, a number of calculi being removed on each occasion from a small sacculi situated at the base of the bladder, with which it communicated by a narrow opening. After the second operation, which was performed two years and a-half ago, a permanent suprapubic opening was established in the hope that, by regular irrigation of the bladder, the attacks of cystitis, to which the patient was very liable, might be prevented, and at the same time an exit provided for any calculi which might again form. This treatment had been attended by satisfactory results, for the cystitis had been kept in check, and a few months ago a stone had been discharged through the suprapubic opening.

SPLENIC ENLARGEMENT.

Dr. WILLIAMSON showed a case of splenic enlargement which he believed to be the early stage of so-called splenic anemia. There was no excess of leucocytes in the blood, and the lymphatic glands were not enlarged. The spleen was increasing in size, and epistaxis had recently become a troublesome symptom. In a similar case, in which there was no excess of leucocytes in the blood up to the last, he had found the splenic pulp, on pathological examination, to be crowded with numerous large cells, each containing several (five to eight) red corpuscles.

THE BRITISH LARYNGOLOGICAL RHINOLOGICAL AND OTOLOGICAL ASSOCIATION.—At a meeting on October 18th, Dr. STOKER, President, in the chair, Dr. R. N. Wolfenden was elected hon. treasurer and Mr. Richard Lake, F.R.C.S., joint hon. secretary. The following cases were shown: Dr. EDWARD LAW: a case of Double Antral Disease.—The PRESIDENT: (1) a case of Syphilitic Ozena treated successfully by the local application of Oxygen Gas, (2) a case of Paresis of the Left Vocal Cord.—Dr. DUNDAS GRANT: (1) a case of Sunken Cicatrix of the Left Membrana Tympani treated by Intratympanic injections of Paroleine, (2) Cholesteatoma of the Middle Ear.—Dr. WILLIAM HILL: case of Regeneration of Left Inferior Turbinate Body after Turbinotomy.—Mr. BARK showed a Rhinolith.—Dr. DUNDAS GRANT opened a discussion on the treatment of Ménière's symptoms. They depended either upon disease affecting the auditory nerve directly (in its intracranial course, or in its labyrinthine distribution) or directly, from increase of tympanic pressure due to various causes in the middle ear. The treat-

ment depended upon the localisation of the lesion, and upon its constitutional character when of this nature. Such conditions as the congestive, anemic, hemorrhagic, and acute inflammatory, as also neuro-vascular disturbances and arterial tension, whether affecting the labyrinth directly or indirectly, called for treatment on the general principles indicated by those conditions. In inflammatory effusions of the labyrinth pilocarpin was of undoubted value, when not contra-indicated by debility. Vertigo arising from indirect irritation of the labyrinth, secondary to middle ear changes, required treatment suggested by the latter, notably resection of ventilation in occlusion of the Eustachian tube with indrawn membrane, removal of granulations causing pressure, tenotomy of the tensor, etc. In "pseudo-Ménière's disease," in which the degree of vertigo was slight, and which was due to a hypersensitiveness to stimulation of the vestibular nerve, and which must be treated by strychnine, arsenic in increasing doses, the bromides, etc.; but quinine in small tonic doses was here of special value. Dr. MACNAUGHTON JONES and the PRESIDENT took part in the discussion.—Mr. LAKE read a paper on a case of Keratosis Obturans, a chronic desquamative dermatitis resulting from the prolonged irritation by hard plugs of cerumen of the walls of the external auditory meatus. In patients of markedly neurotic tendency on absorption of moisture by the mass, with complete occlusion of the meatus, a mild form of melancholia was apt to accompany the increase of deafness. This symptom disappeared with removal of the plug. The best solvent previous to syringing was a collyrium of salicylic acid dissolved in glycerine and water in the presence of a little morphine. In the after-treatment he prescribed an ointment of oleate of lead (10 per cent.) applied with a brush.—Subsequently the PRESIDENT delivered his inaugural address.

NORTH-WEST LONDON CLINICAL SOCIETY.—At a clinical meeting on October 16th, Dr. SIBLEY in the chair, the following cases were shown: Mr. JACKSON CLARKE: (1) A case of Aural Polypus cured by the Application of Alcohol; (2) a patient in whom he had effected Perineal Drainage for the cure of Cystitis.—The CHAIRMAN: (1) Exophthalmic Goitre treated by Supravental Extract; (2) a case of Abdominal Aneurysm.—Dr. CAGNEY: A Child with Infantile Paralysis which he had treated energetically during the acute stage.—Mr. C. P. ALLEN: Cases of Dermatological Interest. Dr. BOULTON, Dr. BULGER, Mr. C. G. BRODIE, Dr. CAMPBELL, and Dr. HERSHELL joined in the discussion on the cases.—Dr. HARRY CAMPBELL gave an experimental demonstration of the Pulse and Arterial Tension with an apparatus of his own invention.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—At a meeting on October 10th, Mr. CHARLES KING, President, in the chair, an address was delivered by Mr. J. H. Targett on the Pathology of Certain Forms of Vesical Tumour. It was copiously illustrated throughout by lantern slides, prepared from photographs of the actual specimens. The first group of preparations illustrated the appearance of certain large single sacculi connected with the urinary bladder by narrow orifices. Much interest was especially taken in the description of sacculi occurring in the lower part of the bladder in the region of the trigone, and probably the result of failure in proper development of this region. Methods for the recognition of these sacculi during life were suggested, and the complications which arose owing to their growth were referred to. In certain cases the possibility of their removal was discussed, and operation was considered to be advisable by the speaker. The second variety of tumour brought forward was the recto-vesical hydatid cyst. It was shown that the cyst originated in close relation with the bladder walls—in fact, in the muscular or fibrous coats—and that therefore the usual statement made in textbooks that they were found in the pelvis, having gravitated to that position from the liver or some other situation in the abdominal cavity was quite erroneous. The operative treatment adopted by Mr. Bond for this class of tumour was recommended and explained. Some exceptionally beautiful preparations were shown of the "villous papilloma" with all the epithelium *in situ*. In connection with these, the speaker

mentioned the difficulty of recognising shreds of such papillomata in the urinary excretion. The most that might be expected to be observed was the very delicate fibrous strand forming the "core" of one of the villous processes. Even should this be found, the diagnosis as to whether the tumour was malignant or not was in no degree advanced for such a complication, as the occurrence of an apparently benign villous growth, covering or depending from a carcinoma, was at times met with. The mode of extension of malignant growths formed a very interesting section of the demonstration. The last subject touched on was the possibility of the ureters becoming proposed and simulating polypi.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The first meeting of the session was held on October 26th, at the St. Marylebone Infirmary, J. R. LUNN, F.R.C.S., President, in the chair. There were several visitors present, amongst whom were Drs. Colcott Fox, Geo. Stoker, and Mr. H. Spencer.—Dr. Colcott Fox delivered a short address on Ringworm. He deprecated the constantly recurring craze for some new parasiticide, which invariably ended in disappointment, chiefly because the proper method of application was not intelligently carried out. He then briefly described the irritant treatment, recommending the use of an ointment containing red oxide of mercury. Dr. F. S. TONGSON (Lewisham Infirmary) spoke of the danger of producing permanent baldness by over-irritation.—Dr. GEO. STOKER described his method and exhibited his apparatus for the treatment of Ulcers of the Leg by the Oxygen Bath.—Mr. J. R. LUNN exhibited cases of Pemphigus Exfoliata; Pemphigus Rash produced by the internal administration of iodide of potash; Functional Chorea; Ankylosis of Lower Jaw relieved by operation; Tabetic Feet, Congenital Pemphigus, Charcot's Disease of the Shoulder-joint. Mr. Lunn also showed a card specimen of Aneurysm of the Thyroid Axis cured by operation.

BOURNMOUTH MEDICAL SOCIETY.—The annual meeting was held on October 25th at the Hotel Mont Dore, when the Committee's annual report and the balance-sheet were submitted.—Mr. C. H. W. PARKINSON, the retiring President, gave up the chair in favour of Mr. D. O. EMBLETON, President-elect.—The following officers were elected for the ensuing year:—*Vice-President*: Mr. G. Mahomed. *Treasurer*: Dr. Kinsey Morgan. *Secretary*: Dr. H. G. Iys. *Librarian*: Dr. S. L. CLAR. *Committee*: Mr. A. C. Kemble (Poole), Dr. W. H. I. MARRINER, Dr. C. D. MASPATT, and Dr. F. W. RAMSAY.—The annual dinner took place after the meeting. Twenty-three members and seven guests were present.

MENIO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the South-Western Division was held at Wonford House, Exeter, on October 14th. Dr. Merton, Dr. Rutherford, Dr. McLean, and Dr. Laslett were elected members of the Association.—Dr. DEAS opened a discussion on The Uses and Limitation of Mechanical Restraint as a means of Treatment. Dr. DEAS's remarks were followed by a prolonged and interesting discussion. Dr. MERTON read notes on three cases of Spontaneous Gangrene. It was agreed that Dr. MacDonald's paper on the Nursing Staff should be the subject for discussion at the next meeting. The spring meeting was fixed for Tuesday, April 14th, 1896.

REVIEWS.

DISEASES OF THE SPINAL CORD. By BYROM BRAMWELL, M.D., F.R.C.P., F.R.S. Edin., Assistant Physician to the Edinburgh Royal Infirmary, etc. Third edition. London: William F. Clay. 1895. (Demy 8vo, pp. 672, 170 illustrations. 10s.)

Dr. BYROM BRAMWELL's work has been so widely read in this country and abroad that the issue of a third edition, thoroughly revised and brought up to date, will be heartily welcomed. In the new edition many of the defects in the earlier have been remedied. The illustrations are not now confined to drawings of pathological sections, but include

abundant representations, taken during life, of Charcot's joint disease, of the various forms of muscular dystrophy, and many other conditions, which have been most effectively reproduced from photographs. Whole sections have been added on muscular dystrophies, syringomyelia, and other conditions which have recently attracted attention. The other parts have been expanded and brought thoroughly up to date.

We are glad to see that Dr. Bramwell resists the temptation to linger over rare and interesting conditions; and is most liberal in the space he gives to the commoner diseases which every practitioner is sure to meet, such as infantile paralysis, locomotor ataxy, and disseminated sclerosis. The lectures on disseminated sclerosis in particular show how thorough has been the revision of the work. Dr. Bramwell has incorporated the gist of the important discussion initiated by Dr. Buzzard at the Newcastle meeting of the British Medical Association, and the discussion on the differential diagnosis of this disease which is so common, but so often mistaken for pure hysteria, is admirably clear and up to date.

Where the standard is throughout so high, it is difficult to single out articles of special excellence, but the lectures on the Progressive Muscular Dystrophies and on Syringomyelia may be recommended as giving as clear and accurate accounts of these important conditions as is to be found in the English language. The section on Railway Spine also, which concludes the book, is most instructive and judicious in tone. We strongly recommend the book to busy practitioners who desire a full, accurate, and pleasantly-written textbook on diseases of the spinal cord. The manner in which the book is printed and illustrated reflects much credit on the publisher.

DIET IN SICKNESS AND HEALTH. By Mrs. ERNEST HART, formerly Student of the Faculty of Medicine of Paris, and of the London School of Medicine for Women. With an Introduction by Sir HENRY THOMPSON, F.R.C.S., M.B. Lond. London: The Scientific Press. 1895. (Demy 8vo, pp. 332; 17 illustrations. 8s. 6d.)

THE importance of the subject to which Mrs. ERNEST HART has devoted this volume will not be disputed by any practical medical man. A great physician desired that the only inscription under his name on his tombstone should be "He fed fevers," but, to judge by their practice, it would seem that too often the most careful housekeeper is disposed to believe that the culinary art is wasted in cooking for the sick or the convalescent, whereas it ought here to find its highest expression. "No man," to quote the pregnant words of the introduction which Sir Henry Thompson has written for this volume, "is a really accomplished physician or surgeon who has not made dietetic principles and practice an important part of his professional education." The truth will be admitted also of his further remark that "a certain familiarity with the resources of the cook is essential to furnish a suitable daily menu, which shall be agreeable to the invalid, and as much as possible varied within the narrow limits which are dictated by the circumstances of each case."

The volume opens with chapters on food and food values, on stimulants (alcohol and coca), and restoratives (tea, coffee, cocoa, chocolate). Thereon follow chapters on underfeeding and overeating, with special sections on the feeding and diet of the aged. The consideration of the arts of "thinning the fat" and "fattening the thin" is followed by a series of chapters on digestion and indigestion. The diet suitable to various other disorders of the digestive system is next described. Much space is judiciously assigned to diet in diabetes, and the authoress is able to show how much variety may, with care and intelligence, be introduced into the commonly dreary dietary of the victims of the disorder; numerous recipes are given, and this is, indeed, a characteristic of the book in every section, for it is essentially a practical guide. Complete menus are given, also, of many breakfasts, luncheons, and dinners suitable for the consumption of diabetics. In succeeding chapters, gout and chronic Bright's disease are treated in much the same way, though not at so much length. The volume contains, also, some notes on diet in fever, and in typhoid fever in particular.

This is a brief outline of the general scope of the work. As

to how Mrs. Ernest Hart has discharged her self-imposed task, we shall, for obvious reasons, prefer, rather than express any opinion of our own, again to quote from the introduction the words of Sir Henry Thompson, than whom there could be no more competent critic of a subject which he has himself so much illuminated by his admirable essays. "I do not hesitate," he writes, "to express my opinion that the present volume forms a handbook to the subject which will not only interest the dietetic student, but offer him, within its modest compass, a more complete epitome thereof than any work which has yet come under my notice. It is so because its accomplished author has the advantage of possessing not only a remarkable acquaintance with the various branches of medical knowledge, after many years devoted to their study, but also in no less degree that which has been conferred by long culinary and housewifery experience. I can strongly commend this book, therefore, as one of large usefulness in its selected sphere."

STUDIEN ÜBER KLINIK UND PATHOLOGIE DER IDIOTIE.
[Studies in the Clinical History and Pathology of Idiocy.]
By Dr. CARL HAMMARBERG. Translated into German by
WALTER BERGER, and edited by Professor S. E. HENSCHEN.
Leipzig: Koehler. 1895.

A CAREER of great promise was cut off suddenly and unexpectedly when CARL HAMMARBERG died on November 1st, 1893, at the age of 28. He had already published some of the results of his careful work, and in the monograph which Dr. HENSCHEN has issued in sumptuous form as the most suitable memento of his young friend and assistant we have the record of researches carried out in the thorough and conscientious manner which distinguishes the neurological laboratory of the University of Upsala.

The object of the investigation was to determine the alterations in number, size, form, and minute structure which the cells of the cortex cerebri undergo in various atrophic conditions, congenital and acquired. Had the author lived, it is probable that he would have supplied neurologists with most of the statistical data so greatly needed by everyone who turns his attention to this subject.

It is difficult to speak with patience of the opinions expressed by pathologists from time to time as to the nature of the changes in nerve-cells which accompany mental disturbance. For the most part they are so perfectly innocent of anything resembling "control" as to be valueless, and there is danger lest after many disappointments we fall into a sceptical attitude of mind and reject all records of changes in grey tissue as unworthy of consideration. The time allowed for *post-mortem* change, the method of hardening, and the method of staining have as a rule a great deal more to do with "departures from the normal type" than the disease. Hammarberg's results are more interesting as supplying definite data regarding the influence of these conditions and processes on the tissue than they are as positive contributions to our knowledge of the micropathology of the cortex, although they are not wanting in interest in this latter respect also.

Section I deals with the influence of hardening reagents, etc., and with the methods which may be trusted for enabling us to count the number of nerve-cells in each stratum of a piece of cortex of definite size. Few investigations are more difficult.

Section II deals with the minute structure of the different regions of the cortex having regard especially to the number, size, and stratigraphical distribution of the cells in men, women, and children at various ages.

In Section III an account is given of the structure of the cortex in nine cases, which illustrate all three classes of idiocy as classified by Schäfer in Ziemssen's Handbook. These reports will form an excellent standard for anyone who may undertake similar work in the future.

Had the author lived he would probably have added a large number of cases worked out on the lines which he has laid down with so much care; but, fortunately, he seems to have analysed his results as he obtained them, and the editor has therefore been able to append to the monograph Hammarberg's own generalisations, which are of great interest and importance. He finds in all his cases a deficiency in the number of func-

tional nerve cells in the brain, not only relatively to the whole cortex (which is of course abnormally scanty in the idiot), but relatively to the area of cortex examined. The cortex remains in an undeveloped or embryonic condition. As a rule the arrest in development is complete only in a small portion, but the growth of the cortex is influenced throughout its whole extent by this patch of undeveloped tissue. The psychical condition of the patient depends upon the period at which arrest of cortical development occurred.

Incidentally the author is able to show that many histological changes which have been described as characteristic of idiocy are artificially produced; when proper care is taken in the preparation of the brain these appearances are not to be seen.

Professor Henschen is to be congratulated upon issuing a monograph which is, at the same time, a valuable contribution to neurological science and a lasting memorial of his gifted assistant. We understand that the proceeds of the sale of this book will be given to Dr. Hammarberg's family.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

OPHTHALMIC TROPACOCAINE TABLOIDS.

Messrs. BURROUGHS, WELLCOME, AND Co., Snow Hill Buildings, E.C., prepare for ophthalmic use a compressed tabloid of tropacocaine, a base occurring associated with cocaine, cocaine, and other bases in Java coca leaves, and to some extent in other coca leaves. Attention was first drawn to this base at the meeting of the British Medical Association at Nottingham by Dr. A. P. Chadbourne, of Boston, U.S.A., who in a paper read before the Section of Pharmacology and Therapeutics described the results of an investigation carried out in the Pharmacological Institute of Berlin University. He showed that in many respects the physiological action of this base differs from that of cocaine. It is a powerful local anæsthetic, and in the eye does not cause ischæmia, or any irritation or hyperæmia. It was found to be only half as poisonous as cocaine, and local anæsthesia was produced more rapidly than by cocaine, and apparently by less concentrated solutions. At the Bristol meeting of the British Medical Association it was stated by Mr. T. J. Bokenham that tropacocaine was found to be perfectly satisfactory for the removal of foreign bodies from the eye, and that it deadened the pain caused by the removal of misdirected eyelashes and the application of caustics to the lids. It is also superior to cocaine in that it produces no paralysis either of the iris or of accommodation.

The name "tropacocaine" is chemically inappropriate because the base is not an analogue of cocaine, but is really one of the class named by Ladenburg "tropeines." Lieberman has shown that the composition of this base is not analogous to that of cocaine, and that when split up under the influence of hydrochloric acid it yielded instead of ecgonine a base isomeric with tropine from atropine, the other product of the transformation being benzoic acid. The new coca base was named benzoyl pseudotropine, and Lieberman succeeded in reproducing it artificially. The name "tropacocaine" was substituted for benzoyl pseudotropine as being more suited for medical use, and suggestive of the chemical relations of this base to atropine and cocaine.

The tropacocaine tabloids are readily soluble, and can be applied directly to the eye. They also possess the great advantages of portability and permanence.

JEREZCONA WINE.

Messrs. HERTZ and COLLINGWOOD, 38, Leadenhall Street, E.C., have introduced, under the name of Jerezcona wine, a solution of the hydrobromic acid extract of cinchona bark in sherry wine. The wine used as the solvent is in every respect

a very good one. The preparation has a very pleasant taste, the bitterness of the extract being scarcely perceptible. The idea of administering the alkaloids of cinchona bark combined with hydrobromic acid is an excellent one, for therapeutic authorities are agreed that hydrobromic acid possesses the power in most cases of preventing that unpleasant train of physiological symptoms which quinine produces in many persons. When it is desirable to give quinine as a tonic, Jerezona wine can be recommended as a most agreeable form of prescribing it.

PNEUMATIC TYRES AND QUIET CARRIAGES.

A PERFECTLY noiseless carriage free from shock or vibration has long been a great desideratum, but until recently an unobtainable luxury. For doctors who commonly spend many hours a day in their carriages the demand for improvement in this respect has, however urgent, been so long ungratified that the rumbling noises and succession of petty shocks endured in riding in a brougham over good or bad roads has come to be regarded as a necessary and essential discomfort. The introduction of cycling, however, led to a still more urgent demand for some means of diminishing the shock and incessant vibration of rapid transit, and the ingenuity thus sharpened produced a vast improvement in the Dunlop pneumatic tyres, which has now been successfully applied to hundreds of thousands of cycles. Since 1883 this pneumatic tyre has been successfully applied on a large scale to some thousands of carriages, and it is said with complete success. The jolting motion of a carriage on the old iron-shod wheels is completely obviated by the use of these tyres, a conversation is as easy as in the study armchair, and vibration is reduced to an absolute minimum. We find that with wheels so fitted it is impossible to tell whether the carriage is

passing over wood pavement, newly made roads, or granite setts, thus the perfection of ease is obtained, while the carriage is absolutely noiseless. The reduction in the draught of the carriage is estimated at at least one-third, so that horses are thus enabled to travel further and faster with less labour. A great saving is claimed in horse flesh. This economy extends even more markedly to the wear of the wheels and of the carriage generally, and while the Dunlop pneumatic tyres are

so durable that they are guaranteed to last far longer than solid rubber tyres, they are found to be especially suitable for use on the roughest roads. In towns and streets fitted with tramways they have the great advantage of not catching in the tramlines, so that skidding is obviated. The tyres are fitted to the existing wheels of a carriage without difficulty, and the appearance of the wheel is practically unaltered. They are so durable that they are calculated to run 30,000 miles, and no one who has tried a carriage fitted with these pneumatic tyres is likely to be satisfied with anything less comfortable. We are inclined to think that they are essential for ambulance and invalid carriages, but as a matter of comfort, health, and luxury they will probably be considered hardly less desirable for everyone who has much use for a carriage, and especially for a close carriage, and we look to see them come into very general if not universal use. Their quietness would be a public boon. If all that is claimed for them in respect to saving of the wear and tear of horse flesh, and therefore diminution of cost of the stable, and to the great saving in the life of the carriage owing to the absence of vibration and shock, be true—and there is good reason to consider that the estimates are not overestimated—the prime cost

of the tyres will be quickly saved; this is to consider the question as a mere matter of economy, apart from the enormous increase of comfort and diminution of fatigue.

LATTICE ELASTIC STOCKING AND LEGGING.

THE "Varilat" Lattice Elastic Stocking Company (70, Fenchurch Street, E.C.) have prepared a fenestrated stocking of red rubber, which is intended to afford in cases of varicosity of the lower limb a sufficient degree of protection and support without exerting too much pressure and causing obstruction of the enlarged veins. The support is given by bands of elastic of sufficient width traversing the limb like lattice work. The support, it is asserted, is ample, and the short columns of blood in the veins between the bands are sustained in transit. This appliance seems well adapted to meet a want and to prove not only soft and comfortable to the wearer, but also cleanly and lasting, and in the long run less costly than other forms of elastic stocking. In severe cases, however, it will probably be found necessary to apply a continuous and more extended pressure in order to assist undue bulging of the thin-walled and distended vessels.

IRON COMFITS.

Messrs. ROBERTS AND Co., 76, New Bond Street, W., are the agents for a French pharmaceutical preparation made by A. Cognet, pharmacist, of Paris. The basis is oxalate of iron, a compound stated by Dr. Hayem, Professor at the Paris Medical Faculty, to be superior to all other ferruginous preparations. The oxalate of iron is combined with quassine, the crystalline neutral bitter principle obtained from quassia wood. The elegant and very tempting form in which the combination is made, that of a pink sugar-coated pill or comfit, will ensure their easy administration.

THE HEALTH AND SANITATION OF CALCUTTA.

THE report of Dr. W. J. Simpson, Health Officer of Calcutta, for the year 1894, gives an exhaustive and most interesting account of the sanitary condition and requirements of the capital town of the Indian Empire. The year was, meteorologically, a normal one; but the price of food was higher than usual, and Calcutta, in common with the surrounding districts and towns, was very sickly. The death-rate—32.9 per 1,000—was in excess of any of the preceding five years. Children under 1 year of age died at the rate of 402.4 per 1,000. There was a marked and alarming rise in the prevalence and mortality of fever. Dr. Simpson discusses this subject at length in connection with the question of drainage. He shows that the "canal area" of the town, "undrained, waterlogged, and sewagelogged," presented the highest fever rates; and contends that remedial measures are urgently and immediately required. He condemns the present drainage and sewerage system of Calcutta, which has cost the city some 100 lakhs of rupees, in uncompromising terms. In this he is fully supported by Mr. Baldwin Latham, who in the year 1891 made a most careful investigation of the system, indicated its grave defects and faults, and made a number of suggestions for their remedy.

Calcutta is a very difficult subject for effective drainage, but the statement that "the outfall is obstructed by tidal influences, and the sewers leak and contaminate the soil," is of itself sufficient to prove that the present state of the combined underground drainage and sewerage is dangerous to health in the highest degree. The increased supply of water to the town and the improved arrangements for flushing have added to the volume of material which these pipes are unable to dispose of, and which consequently stagnates and deposits its solid elements, while the liquid soaks into the soil. The frequent rain storms which occur in the hot and rainy season cause, in combination with defective outfall and other aggravation of habitual faults due to physical obstacles, mistaken designs, and bad construction. Mr. Latham's views and suggestions have now been before the Commissioners for over

four years, and in the face of the serious increase of fever mortality, which in India is always attributable to defective drainage, it is full time that something were being done. Cholera, though far below the level of former years, was twice as fatal in 1894 as in the preceding year. Dr. Simpson devotes many pages of his report to an account of an investigation made by himself and Professor Haffkine regarding the presence of comma bacilli in tank, well, and hydrant, river and canal waters, milk, curds, flour, air, and drains. They discovered bacilli in 91.8 per cent. of tanks around which cholera prevailed. The hydrant waters were found to be free of these organisms. The other materials gave uncertain results, and further inquiries in this line are obviously necessary. The results of vaccine operations, conducted according to Haffkine's plan both in Calcutta and elsewhere, are detailed at length. These results have been already fully described and discussed in the *BRITISH MEDICAL JOURNAL*. They are on the whole promising.

Small-pox prevailed in Calcutta with epidemic activity, causing 405 deaths. It is shown conclusively that the mortality among the vaccinated was trifling as compared with the unprotected. Vaccination was pushed, and other appropriate sanitary measures resorted to; Calcutta is a very difficult place to vaccinate. The inhabitants are largely migratory, and unprotected subjects are constantly entering the town, while infants are removed or lost sight of before the year within which the law requires vaccination has expired.

The most important part of Dr. Simpson's report is that which is devoted to the need of proper building laws and regulations to prevent overcrowding, and the production of conditions which render the sanitation of a town impossible. He proves by descriptions and plans that building operations are being at present conducted in a manner which is most detrimental to health, and is likely in the future to become more so, while the discretion which the law allows to the Commissioners is exercised in opposition to the views of their own sanitary and engineering executive in the direction of sanctioning constructions which are inconsistent with the most elementary rules of healthy urban existence.

The health officer's representations are sound, and indicate most conclusively the need of new building regulations framed on scientific principles, and administered with firmness, if Calcutta is to be saved from sanitary disaster and extravagant expense in the future.

The report presents in great detail the work done by the health department, which appears to be energetic and wisely administered. Many of the elaborate statistical tables appended are either valueless on account of the imperfection of registration, or fitted rather for departmental use than general information. It seems a pity that a document which, unlike most Indian sanitary reports, contains so much really good sanitary information, should be burdened with so large a load of petty or unreliable arithmetical material.

THE LABORATORY OF CHEMICAL PATHOLOGY AT UNIVERSITY COLLEGE, LONDON.

THOUGH the importance of the application of chemical methods to the study of pathological problems may be very generally admitted, hitherto this has remained in this country little more than a pious opinion very suitable to be the topic of an introductory address or some annual oration. A serious attempt to carry the principle into action is deserving of hearty recognition.

Some years ago Dr. Vaughan Harley was appointed teacher of chemical pathology in University College, London. Through the initiative of Mr. Victor Horsley, the professor of pathology, Dr. Harley was some time ago nominated assistant professor of pathology, and has been placed in charge of a laboratory which has been assigned for the purpose by the Council of the College. The laboratory consists of three rooms fitted with the necessary apparatus, and there are in addition a balance room, and a dark room which can be used for the purposes of the laboratory. The largest of the rooms is fitted as a class room, and in it courses of chemical pathology are given. These classes (which have hitherto

been attended principally by qualified men) afford a general introduction to the clinical applications of chemical pathology. The courses are practical throughout, the member himself performing all the examinations and analyses. The first course, entitled clinical chemistry, deals with the blood, with the secretions of the alimentary canal, with sputum, with pathological fluids such as exudations and cyst contents, and with the urine. The course of chemical pathology deals with the methods employed in the investigation of diseased processes and in original research. Under this head we find the more complicated examination of the blood, more advanced work as to the chemical changes in the saliva, and the gastric and intestinal contents as to the chemistry of the sputum, as to the bile, and as to pathological fluids. Milk also is examined in this course, and there is an advanced course on the urine.

Another room belonging to the department is fitted up for research work, and among those who are now or were recently working there are several investigators who have received grants from the Scientific Grants Committee of the British Medical Association. In a third small room is a blood-gas pump worked by a water motor, and a large respiratory apparatus, after the plan of Züntz, for the analysis of respiratory gas exchange under various pathological conditions.

The complexity of the processes involved in accurate chemical work in pathology, and the tedium of repeating many times the same manœuvres, must always deter many anxious for immediate results from this field of work, but Dr. Vaughan Harley has devoted much thought and ingenuity to simplifying the actual work and shortening the time which analyses take. In the research room, for instance, the apparatus is so arranged that the fat extractions and estimations of nitrogen can be made six at a time, and other time and labour saving devices are in use. An adequate apprehension also of the difference in the standards of accuracy required for original chemical research, and for the establishment of clinical facts within a reasonable margin of error, is also apparent in the arrangement of the class-room. This is a point of no little importance, for if chemical pathology is to render to practical medicine the services which it is undoubtedly possible for it to give, it must be by the adoption of approved processes in which the margin of error is known, and is within the range of accuracy required for clinical work.

The department which we have here briefly described deserves to be better known and more generally utilised by those who have the opportunity of giving a few months, or even only a few hours a week for a few months, to the acquisition of knowledge, and we may perhaps add dexterity, which, if they serve no higher purpose, will at least render the ordinary clinical analyses more accurate and more speedy.

The importance of providing facilities for such classes has, we understand, been appreciated by the authorities of University College, Liverpool, where Professor Robert Boyce has been enabled recently to establish courses of a character similar to those at University College, London.

THE opening meeting of the Odontological Society of Great Britain will be held on Monday next at 8 p.m., when the President, Mr. David Hepburn, will deliver his inaugural address, and the discussion on the Immediate Regulation of Irregular Teeth will be resumed.

GEHEIMRATH DR. FRANZ KÖNIG, Professor Ordinarius of Surgery in the University of Göttingen, has accepted an invitation to succeed the late Professor von Bardeleben in the Chair of Surgery at Berlin. Professor König is well known by his contributions to surgical literature, notably his *Lehrbuch der Specieellen Chirurgie*.

HOSPITAL SUNDAY FUND.—The £904 announced as having been received by the Hospital Sunday Fund from the Guesdon bequest represents three-quarters of a year's interest on the sum of £45,346 Consols, being part of the residue of his estate, amounting to over £200,000 which Mr. W. A. Guesdon bequeathed to his English executors—Messrs. James Robert Laing, Edward Hunt, and William Astle—to be applied by them at their discretion to such philanthropic and charitable purpose as they should consider most deserving of support.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, NOVEMBER 2ND, 1895.

THE FIFTH YEAR.

The introductory address lately delivered by Mr. Tobin, F.R.C.S.I., to the students of the St. Vincent's Hospital, Dublin, contains many topics of more than purely local interest. As will be seen from the brief abstract published on October 26th in our columns, the difficulties of the Dublin teachers are similar to those which press with scarcely less insistence upon their brethren in the metropolis, and the remedies for them are, perhaps, hardly so easily come by as Mr. Tobin, with the enthusiasm so well befitting the beginning of a new session, would have us suppose.

Mr. Tobin, with a patriotism at once warm hearted and clear eyed, notes that the Dublin hospitals no longer attract outsiders in any considerable numbers. Nowhere, says he, as you walk round St. Stephen's Green or College Green, have you to make way for Australians, Americans, Hindus, Japanese, as you would have to do in the neighbourhood of the chief schools in Scotland or Germany. And why? Mr. Tobin finds an explanation in the simple fact that "they attend better to their business." For ourselves we do not forget that Edinburgh has but one Royal Infirmary, whilst Dublin, with a population adequate, perhaps, to the maintenance of one Protestant and one Catholic hospital upon a generous scale, endeavours to maintain a host of small mutually competing hospitals which are under no circumstances likely to attract those foreigners who desire to see as much as possible with the least possible expenditure of time. In London the difficulty is somewhat the same, though with us the remedy is probably to be sought, not in the suppression of the smaller general hospitals, but in a better disposition of them according to the needs of the vast population they exist to benefit, or—as a less costly alternative—in the establishment of outpost stations with the best ambulance service attainable.

Mr. Tobin, however, seems to be even more concerned with the vexed question of curriculum than with the proportion of hospitals to population. Five years the General Medical Council, whose writ runs even in Ireland, demands of the medical student, and how best is he to spend the appointed time? Mr. Tobin as a clinical teacher first and foremost is all for clinical work, so much so that he advises the student even in his first year, and certainly in his second, to go round the wards. Herein the authorities of most of our London schools would, hardly be found to agree with him, though it used to be the case—and for all we know may be so now—that six months' hospital practice was

required of the Cambridge student before admission to the Second M.B. It is nevertheless pretty generally thought that a student is wise to defer "walking the hospital" till the examination in anatomy and physiology has been passed, though it is too much to demand of poor human nature that the average man will entirely forego in his ardent novitiate the sanguinary attractions of the operating theatre, unless rigidly excluded therefore by the great goddess, *aspeila*. Some day her sway will be absolute, but the time is not yet. The gravamen, however, of Mr. Tobin's charge appears to be that the student's education is every day becoming more and more a matter of cram and examination knack, and less and less a training of the faculty of observation, in which, as he rightly insists, the chief value of education lies. This degeneration he attributes mainly to the prevalent habit of neglecting bedside work in the hospitals for attendance upon the lectures given by the professors attached to the licensing bodies, and students are, he believes, encouraged in their courses by the manner in which the regulations for examinations have been framed. "The regulations," Mr. Tobin states, "order that the theory of medicine and surgery is to be condensed each into a course of fifty lectures to be given in schools which are in reality schools of anatomy, physiology, chemistry, and physics, and they refuse to recognise systematic theoretic lectures given in hospitals in conjunction with practical work; and further the regulations are armed with a revolver, in the shape of examinations, which enforces the obedience of students."

Now, if this quotation represents the actual state of affairs in Dublin, there can be no doubt that Mr. Tobin is justified in raising his protest. Clinical observation and clinical teaching must ever be the basis of every right system of medical education, and the "set and rounded discourse" admired by our predecessors is, with the easy accessibility of textbooks and monographs, every day becoming of less importance. To diminish the number of systematic lectures whilst increasing the number of clinical lectures and catechetical classes is the aim of most of those who are now striving for reform in educational methods. Such reform must of necessity be slow, opposed as it is to the conscientious convictions of those seniors who have failed to realise how altered are the present conditions from those which prevailed in their student days.

The last suggestion of Mr. Tobin which we have space to notice is that candidates for the final examination should be examined by the teachers of the hospital from which they present themselves. We are aware that the plan thus advocated has commended itself to many good authorities, and did, indeed, find a place in one of the numerous schemes for the reform of the London University. Nevertheless, we are bound to say that the abuses which such a system might entail appear to us to outweigh its supposed advantages; and whilst the clinical side of medicine should be well represented upon the court of examiners, it is better in our judgment that the examiner should have no previous acquaintance with the examinee.

With this short notice we take leave of Mr. Tobin's suggestive address, which may be commended in its entirety to the careful consideration of all those who wish to see the Dublin schools take their rightful place in the ranks of medical progress.

THE INFECTIOUS HOSPITAL PROVISION FOR LONDON.

THE Sanitary Committee of the Marylebone Vestry have recommended the Vestry to convene a conference to consider the position of the Asylums Board to provide adequate accommodation for the infectious sick. We are not surprised that this course should be adopted, for year after year the Asylums Board has failed to find accommodation for some of the many sick who seek admission into its hospitals. But the question which underlies this proposal is what is adequate accommodation? Does it mean that the total number of persons who may desire or whose friends may desire that they shall enter the hospital are to be received? Or does it mean that only those are to be received whose circumstances demand they shall be isolated at the expense of the ratepayers? If so, who is to decide between those who must be removed and those who shall remain at home? The constitution of the Asylums Board must be considered in this connection, for it is not constituted in such a way as to indicate that it is to provide for any but the poor; and yet it is expected, through the system of admission which has been designed in connection with it, that it shall open its doors to all comers. The Sanitary Committee of the Marylebone Vestry propose two points to be considered: (1) Whether it shall be elected directly by the ratepayers as a separate Board; or (2) whether its powers and administration shall be transferred to the County Council. We do not think any doubt will be entertained by the more thoughtful of the delegates who attend the conference as to which of these two alternatives is the better.

It is practically impossible for two bodies to represent London for the purposes of disease prevention each directly elected by the ratepayers. With the duty of hospital provision must eventually be associated vaccination, and such duties of inquiry into infectious disease causation and prevention as may properly belong to a central metropolitan health authority. This, we take it, is inevitable, and it needs but little foresight to appreciate the confusion that would result from the existence of two bodies having duties so closely allied as those of the Asylums Board and County Council would then be. The only question therefore which remains is whether the Asylums Board should remain as it is, and the scope of its duties be more clearly defined. Experience has, we think, shown the impracticability of adopting this course. To have the Metropolitan Asylums Board as an indirectly elected body over whom the ratepayers have no control means to leave it subject to the supervision, in all its actions, of the Local Government Board. The past has shown the result of such an arrangement. The managers are necessarily restricted in their work, for the Local Government Board cannot divest itself of its responsibility, and when a breakdown occurs the two Boards endeavour to cast the blame on each other. Then the Asylums Board endeavours to do in a few weeks work which requires as many months or longer, and the ratepayers are left to pay the price which hurried work always costs. It is time that an end was put to this unsatisfactory position, and we trust the action of the Sanitary Committee of the Marylebone Vestry will lead to the complete change which all who have studied metropolitan health administration must have seen

to be necessary, and thus bring the hospital provision of the metropolis into line with the machinery of disease-prevention which already exists, and which includes all the medical officers of health of London.

THE CASE OF MISS LANCHESTER.

THIS week the above case has caused a great deal of stir, and as it concerns the treatment of a lady as an alleged lunatic it deserves immediate notice, though possibly at present we have not the whole of the evidence necessary to judge of the conduct of the medical men concerned. We have, however, substantially their statements and those of the other parties. The case then appears to be that a lady who for some time had been living an independent life, and who had made up her mind that women should be emancipated, had openly declared her intention of disregarding social rules and living with a man below her in station. Such conduct was considered by her parents as evidence of insanity, and they wished to save the lady from her own act. Parents still believe they have some rights, and that they have an interest in the good name of the family, but they must be careful not to transgress the law in trying to do good to an individual. The lady was forcibly seized by her relations after having been seen, and certified as of unsound mind, by a leading physician, and on an urgency order she was taken to an asylum; she was seen by the Commissioners, who, according to one evening paper, expressed regret that they could only advise the lady but could not control her acts. They were convinced that her symptoms did not represent any definite mental disease, and that therefore they must order her discharge from certificates. No complaints of any kind are made against the asylum. The point remains for consideration, whether the physician was justified in signing a certificate of lunacy under the circumstances.

Recently papers were read before the Association on Insanity of Conduct, the authors maintaining that the only evidence of mental disorder may be seen in the acts while the faculties of mind may appear to be normal. This, of course, is a doctrine involving far-reaching consequences and opens very dubious questions.

It is possible that the conduct of Miss Lanchester appears to be highly unreasonable; but everything depends upon the way in which a change in character has developed. No one will deny that the disregard of moral and social laws is among the earlier symptoms of insanity; therefore, if a person who has always led a strictly conventional life suddenly gives rein to his feelings, we are prepared to watch for other symptoms of loss of control. If, on the other hand, the change in character and in acts follow a slow course of development which bears a direct relationship to the surroundings, it cannot be considered or treated as disease.

It would be a reversion to the long past to treat individual disregard of social conventions as criminal or lunatic. Dr. Blandford, who gave the first certificate, is an alienist physician of long experience, eminence, and high character. He studied at Oxford, and graduated M.A. and M.D. in 1854, when this distinction was rarer than it is now. He is lecturer on psychological medicine at St. George's, and the author of the article "Insanity" in Quain's *Dictionary of*

Medicine, and has filled more than one high office in his department of medicine.

All who know Dr. Blandford are certain that he has been influenced solely by conscience and conviction as to the act he performed in signing an urgency order. We feel very strongly, however, that the urgency order is a very powerful weapon which must not be used recklessly, or it may be distrusted by the public. It is a most valuable means for rapidly placing very violent patients under control, but it is not intended for the speedy removal of persons who may have followed a course of conduct offensive to the opinions of their relations.

Dr. J. B. RUSSELL, the accomplished senior Medical Officer of Glasgow, has been compelled, we regret to know, to apply for six months' leave of absence, following on a prolonged and severe attack of illness. The Council, in granting the request, have coupled their consent with the expression of their hope that at the end of that time "he may be able to renew his valuable services to the city," and his professional brethren, who may be presumed to look upon his work with even more discerning eyes, most cordially re-echo the hope and endorse the language in which it is expressed.

EDINBURGH ROYAL MEDICAL SOCIETY.

The session was to have been inaugurated on October 25th with an address by Dr. Clouston, of the Royal Edinburgh Asylum, who unfortunately was prevented by illness, and the evening was occupied with papers by Dr. Parves Stewart and others. It is expected that Dr. Clouston will give his inaugural address on an early day.

THE GENERAL MEDICAL COUNCIL.

We understand that, owing to unforeseen difficulties of a legal nature which have intervened to delay the building works at the house of the General Medical Council in Oxford Street, it will probably be necessary to postpone the meeting of the Council. In the ordinary course it would have commenced on November 26th, but it is possible that it may be found most convenient not to assemble the Council until after Christmas. There appear to be indications that the vigorous action of the Council in recent years in penal cases has had a very favourable effect. We understand that the number of cases now under investigation by the law officers of the Council, in which it is charged that the regulations of the Council as to "covering" or irregular practice have been violated, is comparatively small, and that but few are as yet in a sufficiently forward state to be brought before the Council for adjudication.

NURSES IN IRISH WORKHOUSES.

We are naturally much interested in the struggles which are just now going on between the Irish Local Government Board and many Boards of Guardians in that country on the nursing question. Our own views are now pretty well known, based as they are upon the reports of our Commissioner in Ireland. We sympathise with the Local Government Board in their contest, because, although two out of the three members of that body are Roman Catholics, writers who ought to know better are attacking them as if they were making an assault upon religion. We are sorry to say that that is a great difficulty in dealing with many reforms in Ireland, and in this particular instance a very dishonest attempt is being made to prevent improvement by arousing animosities and by imputing motives which certainly do not exist. It is a pleasure, then, to see the fair judgment of such papers as the *Irish Daily Independent* and

the *Leinster Leader*, both of which have approved of the proposed change from untrained to trained nursing. For the first time, by means of our Commission, the Irish public is getting a general view of their workhouse system, and particularly of the neglect of the sick poor, and it passes our comprehension how any people—always excepting Boards of Guardians—could try to thwart a movement which only aims at improving conditions which are a discredit to the humanity of the country.

SIR CHRISTOPHER NIXON.

On Thursday, October 24th, Sir Christopher Nixon, Physician to the Mater Misericordiae Hospital, Dublin, was entertained at dinner in the Shelbourne Hotel, in celebration of his having been recently knighted. The Right Reverend Monsignor Molloy occupied the chair, and there was a large company, including many members of the profession. Amongst those present were the Right Hon. C. Redington, the Roman Catholic Bishop of Galway, Sir John Banks, Sir Thornley Stoker (President of the Royal College of Surgeons), the President of Queen's College, Belfast, and the President of Maynooth College. The Chairman proposed the guests' health, and Sir Christopher Nixon, in replying, declared the honour which his friends had done him to be the greatest reward of his life.

THE REGIUS PROFESSORSHIP OF SURGERY AT DUBLIN.

The Council, in whose hands lies the appointment to the Regius Professorship of Surgery in the University of Dublin, vacant by the death of Sir George Porter, met on October 23rd. There were three candidates—Dr. E. H. Bennett, Professor of Surgery in the Medical School; Sir W. Stokes, Professor of Surgery in the Royal College of Surgeons; and Dr. C. B. Ball, University Anatomist. The proceedings were complicated by the candidature of Dr. Bennett, whose position as Professor of Surgery was supposed by some to exclude him from this appointment. A great deal of discussion ensued, and finally the meeting was adjourned to November 6th. The contest excites much interest.

CHURCH CATARRH.

To those who are not in perfect health few things are more calculated to give rise to any malady to which they may have a tendency than sitting in a chilly church after the sharp walk which the ineradicable tendency to starting late seems to impose on all churchgoers. Perhaps the worst error in warming churches is committed by those who put off the commencement of the process until Saturday night, or may be Sunday morning, and then fire up hard to get things ready for 11 o'clock. The windows are kept closed for fear of losing heat; the stagnant air, with which those who visit churches on the week-day are so familiar, is warmed up for Sunday use, but the walls remain cold, and when service commences, hot and even burnt as the air may feel, there is no warmth in the building. Worshipers are thus subjected to the worst possible combination of surroundings—bad ventilation, foul atmosphere, draughts from internal currents, and the respiration of hot air while sitting in a building which is cold. The problem is not how to warm the air alone, but how to warm the church itself. This is necessarily a slow process, and it is doubly slow where, as is commonly the case, the attempt is made to use the same apparatus to warm the church that is employed for warming the incoming air. Unless, as in some cathedrals, stoves are placed actually within the church so that radiant heat is available, we doubt whether it is possible in cold weather to make a building fit for Sunday use without keeping up the fire all the week. This is not so much a matter of coal as of labour and supervision. A little fire all the week, with only just enough ventilation to keep the air sweet, will do far more to make the fabric warm than a great blaze for a few hours; and

after all, what is wanted much more is to warm the fabric, so that every stick and stone shall radiate a sense of comfort. When churches are too hot from over-firing, people catch cold in consequence of the draughts which are produced and from the chill on coming out again. These are what one may call honest colds—stiff necks, neuralgias, lumbagos, and sometimes "cold in the head"—things they might catch anywhere from sitting in a draught even of pure air. Unfortunately too often the heat is the heat of closeness rather than of excess of fire, and then the results are much more deadly. Added to the evil of the draughts are the toxic effects of breathing again the breath of others, and absorbing the exhalations of their fellow worshippers. From such influences arise too often those depressing colds which, in fact, were till 1880 called "influenza colds," with streaming eyes and nose, feverishness, and depression, drifting sometimes into an almost suppurative post-nasal catarrh, with great exhaustion.

RATIONAL DRESS IN FACTORIES.

THE frequency with which grave or fatal accidents, occurring among the women workers in factories, are proved to have been caused by the entanglement of their loose skirts or, more rarely, of large sleeves or long hair in some part of the moving machinery has suggested, as a field of work for the promoters of "rational dress" among women, the "mill" as offering more solid advantages than the road, the river, or the moor. But men's dress, though as a rule safer, is in some respects open to improvement, the frock coat of the higher artisan and the blouse of workmen of all classes on the Continent being especially dangerous. Prompted by such considerations Mr. H. Lion, a manufacturing clothier at Düsseldorf, has devoted attention to the production of a "normal dress" for the working man, close fitting without interfering with the freest movement; cheap, durable, and washable without loss of colour. He seems to have attained his end in a strong blue canvas or sailcloth. He has also succeeded in rendering the material quite incombustible by impregnating it with a solution such that, though the strength, colour, and washability of the material are in no way diminished, it will stand several minutes' exposure to a powerful gas flame with no result beyond the singeing of the loose fibres or nap. Fireproofing of fabrics is far more generally practised in Germany than it is elsewhere, and we may take this opportunity of mentioning one example which is well deserving of imitation. In all the principal towns each party of the fire brigade summoned to a fire is accompanied by at least one "Scaphander," a man, whose face is protected by a special vizor and respirator, while his body is clad in a dress into the material of which asbestos enters largely, and is absolutely fireproof. He carries a large sack of the same stuff on his back, enabling him to enter parts of the building impracticable to anyone else, and to carry out the occupants—one adult or two or three children in the fire-proof bag.

UNQUALIFIED ASSISTANTS.

It is difficult to imagine why medical practitioners should continue to risk the dangers they incur by the employment of unqualified assistants. The attendance, if charged for, is a fraud upon the patients, as is pointed out most clearly in the official memorandum issued by the General Medical Council in the following words: "The administrators of the law regard as implicit fraud any claim of payment for the service of such substitute assistants, when it is represented as 'medical attendance.'" In addition to the danger of an action for obtaining money by fraud the medical practitioner runs another risk of being reported to the General Medical Council for "covering," and if convicted is likely to have his name erased from the Register. It would be as well if members of the profession who employ unqualified assistants would realise their danger, as there is no doubt that the

public is awakening to a sense of the fraudulent nature of such unqualified assistance. In a case lately heard before Mr. Wyatt, deputy coroner, in which an unqualified assistant of Dr. Phelan, of 84, Rodney Place, Walworth, had attended and prescribed for the child on whose body the inquest had been held, the coroner, after hearing the evidence, made the following statement: "I am very sorry to say that this sort of thing prevails to an enormous extent. It is nothing short of a fraud on the public. We coroners are powerless in the matter. These cases ought to be taken up by the Medical Society." What "Medical Society" the coroner referred to was not clear, but there is no doubt that if he would forward a copy of the depositions to the General Medical Council that body would cause an inquiry to be held and act accordingly. One incident in the case is worth recording. One of the jury asked Dr. Phelan: "Does your assistant make a practice of attending your patients?" to which the answer was given: "He is just as clever as I am, although not registered." How can the public be expected to differentiate between the qualified and the unqualified, and to understand the advantages which a medical qualification gives when a medical man, himself qualified, can see no difference between the medical knowledge he possesses and that of an unqualified person? Until the members of our profession refuse to associate with or to allow their patients to be treated by unqualified persons very little can be done against the rampant quackery and illegal practice of those outside the profession.

THE SICK POOR IN IRISH WORKHOUSES: CLONES.

IN reading over our Commissioner's report of the visit to Clones Union, we have before us an object lesson of the weakness of the Poor Law as at present administered. In the hospital there are a number of sick and helpless inmates, some of them very ill; for instance, a patient who had fractured the neck of the femur, an unruly pauper suffering from rheumatism and placed in a room alone, a case of burn caused by falling on the fire in a fit, and to these we can add the helpless cases of both sexes. The hospital holds forty beds, the average occupied being twenty-five. To nurse these patients we read there is one nurse, untrained, assisted by females with illegitimate children, described by the medical officer in his report as being "ignorant and indifferent"; these two characteristics, of course are excellent qualities in a nurse. The male side of the infirmary is locked at night, and the patients are left in the dark with such aid as they can render to each other; the females also are in the dark, and share with the illegitimate infants the attention of the "ignorant and indifferent" mothers. The sanitary appliances are so contrived that the atmosphere of the wards is saturated with the odours of the excretions of the patients for the eleven hours or so during which the wards are locked. Of the weariness and helplessness of the patients, the longing for a change of posture to relieve the pain of a rheumatic limb or the aching of a fractured bone—on this we will not enlarge, for the thought is too full of pain; we are writing for those who know how human suffering can be alleviated by timely and skilled assistance, and our readers can fill in the blanks for themselves; but the moral that we wish to point through the suffering of these neglected paupers in the Clones Union Infirmary is that the machinery that administers the Poor Law breaks down in dealing with the sick and infirm. A fully qualified doctor is appointed, and by his instructions he is to advise his Board in all questions that relate to the physical well-being of the paupers; added to this, on account of the recent action of the Irish Medical Association, he is required to render a detailed report of the nursing, sanitation, and domestic condition of his department. Dr. Henry, the medical officer of this union, has complied with this instruction, has condemned in no

measured terms the inefficiency of the nursing staff and the insanitary condition of the infirmary; he is met with "the Committee do not recommend any alteration in the system of nursing or the sanitary arrangements." What is to be done next? The medical officer cannot censure his employers; he cannot raise one finger to improve the conditions surrounding his patients, and by his outspoken report he may have offended some of those among whom his work lies. Now, then, is the time for the central authority to step in, and by placing a minimum standard in these particulars before the guardians, and making use of the coercive powers with which the Local Government Board is entrusted when all other and milder means shall have failed, to secure for the sick and infirm pauper the care and such conditions that his state demand, and for the medical officer independence.

THE THREATENED EPIDEMIC OF INFLUENZA.

It would, happily, appear that the epidemic of influenza, which it was feared was about to develop in London, has not made any progress, but, on the contrary, shows signs of dying away without causing much sickness. The number of deaths attributed to this cause, which had risen to 8 in the week ending October 19th, fell to 4 in the succeeding week, and, what is even more reassuring, mortality from diseases of the respiratory organs is considerably below the average. The effect of influenza in increasing the number of deaths from respiratory diseases is well known, and while the mortality from these diseases remains below the average for this time of the year, it is fairly safe to assume that epidemic influenza has no hold on the health of the population.

THE DANGERS OF GAS.

The explosion in the Strand has drawn attention to one of the great dangers to which we are exposed from leaky gas pipes, but it would be very wrong to imagine that fire and explosion are the only evils to be anticipated from such conditions. The list of deaths from gas poisoning is by no means a small one, and although by virtue (a most blessed virtue, too) of its offensiveness the presence of gas is generally detected before serious harm has been done, the cases of deteriorated health due to the breathing of a gas-tainted atmosphere are innumerable. The poisonous substance in gas is carbon monoxide, but it is probable that the purest forms of hydrocarbon also tend to produce the headache, sore throat, digestive disturbance, and morning languor which are so often complained of by habitual gas breathers. Both smells and ill-health attributed to defective drains are often a consequence of leaky gas pipes. It seems not to be generally recognised that gas fittings wear out with comparative rapidity, and that they require a complete overhauling every few years. Gas pipes go with a house, they are passed on from tenant to tenant without examination, nails are driven into them, they are hammered up without any solder, joints are made by irresponsible people, and the wonder is not that accidents happen now and again, but that they are so few. A leakage far too small to cause explosion injures health, and we cannot too strongly urge that the proper corollary of gas in a bedroom is an open window. There are many houses, however, in which no amount of domestic carefulness will give protection from the evils caused by gas. It is not every house that is cut off from the street by an open area, and when this is not the case the householder is at the mercy of those responsible for what lies under the roadway. One of the evils of the tight closing of the doors and windows which is so common in winter is that the ground air is drawn into the house. In towns ground air is often highly charged with gas, especially since impervious pavements have become so common, and the responsibility for this should be made to rest on those who cause this defilement. The suppliers of gas, whether companies or municipalities, are permitted to tear up our streets at strange and inconvenient times by Act of Parliament, but

no Act of Parliament has ever given them leave to foul the subsoil with coal gas, or to allow so deleterious a substance to escape into our dwelling-houses. Such an escape is undoubtedly a nuisance, and injurious to health. But to prove its origin is not easy, and this is the barrier behind which public bodies shield themselves from attack.

THE HYPNOTISM OF "TRILBY."

MR. ERNEST HART writes: *Trilby* as a drama by no means corresponds in the development of its hypnotic motive and action with the originally artistic and yet sensitively well-drawn conception of Mr. Du Maurier in his novel. It is, perhaps, dramatically more effective, but it is the hypnotism of the platform and the stage play, and not that of Nature and pathology. In the *Trilby* of Mr. Du Maurier, the influence of direct, open, and positive suggestion, which is the real working power of all "hypnotic" conditions, is the mainspring of the action. The all-sufficient subjective change wrought by this agency is admirably used and developed with subtlety and fine literary effect. In the stage version a new hypnotism appears. Svengali—a magnificent study by Mr. Beerbohm Tree of the weird, unclean, spider-like mesmerist of the school of the popular imagination—a twentieth century Mephistopheles—possesses all the mystic powers of the mystery worker of romance, with a suggestion of decadent demonism. As an impersonation it is one of the highest efforts of histrionic skill seen in modern times. Svengali has a "force" which he passes into Trilby; he hypnotises her from behind unseen; he draws her to him from another room by "force of will;" he is exhausted by the transference to her of "his life." All this is very effective from the stage point of view, but it clothes a vulgar error with the glamour of genius, and it possibly may renew for a time the vogue of the follies and frauds of the sham "hypnotism, mesmerism, and new magic," which I had hoped almost to have driven from the notice of reasonable men. Meantime all London will be drawn to see a most remarkable presentment of the platform "mesmerist," outwardly at his best, or at his worst. Miss Baird's beautiful personality and well-conceived presentation of the hypnotised pupil and victim of Svengali is most attractive and remarkable for some fine touches of intuition and observation.

SIR HENRY THOMPSON.

SIR HENRY THOMPSON's very wide circle of medical friends will feel much pleasure at the complete and conclusively satisfactory result of the action in the Probate Court with which he was concerned. It involved a considerable legacy bequeathed to him by a very old friend, who had been his wife's guardian up to the date of her marriage and for all the subsequent years until his death. This gentleman, who was a solicitor and a bachelor, was well known in the medical quarter of London, in which he resided, and was in frequent communication until the last with members of the profession, for whom he had rendered many small services. The will was executed some years before his death, and his diaries were produced for the whole of that year, showing him to have been actively engaged in legal work and in the fullest possession of his faculties. It was alleged, in opposition to the will, that he was of unsound mind at the time of executing it. Sir J. Russell Reynolds was called to give evidence of a conclusive character as to his soundness of mind and a mass of other evidence was in readiness. Before many witnesses, however, had been heard, the judge expressed his opinion of the validity of the proof of the testator's perfect sanity and disposing power, and the jury at an early stage expressed their satisfaction with this evidence and their opinion that it was unnecessary to hear more on that side, and called for any evidence on the other side. None, however, was tendered, and a verdict was therefore entered in favour of the will, Lord Justice Lopes expressing the opinion

that he had never heard stronger evidence than that adduced, and that in any case he should have ruled in favour of the defendant. Many exaggerated, not to say foolish and ill-advised, preliminary paragraphs have been published in various places, to which Sir Henry Thompson had the dignity and wisdom to make no reply or comment. The result was one which necessarily followed from the overwhelming strength of the bare facts proved. There may have been some temporary annoyance for Sir Henry Thompson, under the circumstances, to endure; but he is all the more to be congratulated on the reticence and firmness with which he dealt with the matter, although of the ultimate decision there could be no question.

THE RADCLIFFE INFIRMARY, OXFORD.

At the last quarterly court of the governors of the Radcliffe Infirmary an attempt was made to reduce the power of the medical staff on the Committee of Management. The following resolution was proposed by Viscount Dillon, and seconded by the Rev. C. J. Fletcher:

That the resolution of January 22nd, 1873, with reference to the honorary medical staff be rescinded, and that the honorary medical staff be represented on the Committee of Management by one physician and one surgeon, such representatives to be elected annually by the whole of the honorary medical staff.

This was opposed by Mr. A. Winkfield amongst others. In his speech Mr. Winkfield first of all thanked those other members of the court who had spoken against the resolution for their kind references to himself and his colleagues. With regard to the history of the matter Mr. Winkfield pointed out that trial had been made of a partial representation of the medical staff on the Committee of Management and of affairs as they were at the present time—namely, the whole of the staff being members of the Committee. The former system had failed, and no adequate reason had been given for altering the latter. Mr. Winkfield showed to the court that the medical officers of the institution were the most regular in attendance at the meetings of the Committee, and that no body of men could have the good of the institution more at heart. In the end the motion was defeated, 4 voting for it and 23 against.

THE BASIS OF MODERN ADVANCE IN TREATMENT.

A FAVOURITE subject for Presidential addresses is the marvellous advance that has characterised both the medical and the surgical treatment of disease during the last twenty or thirty years. Dr. Buzzard went to this source for inspiration when addressing the Clinical Society last week at the beginning of his Presidency. He did not, however, lose himself in a flood of details, but philosophically traced them back to the principles on which the details depend; and thereby avoided the common failing of inability to see the forest because of the trees. The great therapeutic advance has not, as he remarked, followed the lines it was expected to pursue at the birth of the Clinical Society in 1868; it has not chiefly resulted from a better knowledge of drugs and of their power over the body in health and disease. Although there have been small and fairly encouraging advances in this direction, the great bulk of modern therapeutical progress has resulted from the deeper study of disease itself, from a better knowledge of its natural history, and especially of its causes. Pasteur's and Lister's researches have led to "advance in the treatment of disease a thousand-fold more important . . . than the effects wrought by any drug which has appeared or is likely to appear in our *Pharmacopœia*." For instance, the accurate study of the clinical symptoms and morbid anatomy of myxœdema, coupled with experiment on the lower animals, has "resulted in the discovery of a therapeutical method the success of which is not only extremely remarkable as regards the particular disease treated, but the principle involved in which is likely to have still more important and widely-extending effects when more gener-

ally applied." The dependence of the disorder upon disease of the thyroid gland led to the employment of that gland as a remedy for the cure of the disease; and the happy result that ensued was the direct outcome of a rigid recognition of scientific method. In neurology, peculiarly his own domain, Dr. Buzzard showed that affections now known to be due to syphilis or alcohol were formerly uninfluenced in any degree by the various drugs and other remedies employed. In the absence of the key to the cause of the disease success in treating it is almost impossible. In regard to maladies produced by micro-organisms, too (the list of which is daily extending, and in which Dr. Buzzard expects some day to find included many diseases not now generally recognised as having such origin), he hazarded the prophecy that the astounding advance in the prevention and treatment of disease already made is probably as nothing compared with what the future has in store. He considers that recent advances in pharmacology have added to the means of palliating suffering and modifying the symptoms of disease which transcend all experience in the past, and furnish therapeutic agents of the greatest value; but such considerations do not shake his conviction that the chief advance in treatment has resulted from, and will continue to be the product of, deeper knowledge of the natural history of disease itself.

THE HOSPITAL SUNDAY FUND.

A MEETING of the Distribution Committee of this fund was held on October 30th at the Mansion House. It was stated that the receipts up to date were £61,500, of which £45,766 had already been distributed, and a further division of £15,850 among the various hospitals, dispensaries, and convalescent homes was recommended.

GUY'S HOSPITAL.

MR. GLADSTONE's attention, as an old governor of the institution, having been drawn to the financial affairs of Guy's Hospital (whose income, owing to agricultural depression, has been reduced from £40,000 to £20,000), he has written an earnest appeal for help. Addressing himself to the treasurer of the hospital, Mr. Gladstone says: "I wish, but vainly wish, it were in my power to bring London, and not least, the City of London strictly so called, to understand the greatness and urgency of the case. In your report as treasurer you inform us that, from want of pecuniary means, 100 beds are at the present time, and have been for some past period, unemployed and useless. This statement is of itself sufficiently grave, but it is not all, nor is it the gravest of what you have to tell. We have to make ourselves understand that the arrest and contradiction of efficiency thus indicated will be followed, at the close of the present year, by a further and, I fear, yet heavier downfall, and that, unless a courageous and serious effort is made to avert the calamity, an appreciable portion of Guy's Hospital must become a solitude. But such a solitude would be, indeed, a desolation." Dr. Samuel Wilks, as chairman of the Sustentation Fund of Guy's Hospital, has written endorsing Mr. Gladstone's appeal for public support "of an institution which has become almost one of the necessities of life in the working classes." He expresses the opinion that it is the obvious duty of employers of labour to assist those institutions which daily relieve their men gratuitously when wounded or otherwise injured. Contributions may be sent direct to Guy's Hospital, S.E., or to its bankers, Messrs. Lloyds, 72, Lombard Street, E.C.

DIFFICULTIES UNDER THE VACCINATION ACTS.

THE delay in the presentation of the report of the Royal Commission on Vaccination has had many ill results to the country at large in consequence of the steadily increasing number of children growing up in an unvaccinated condition, and the results will only be fully measured as time

goes on and the children come under the influence of small-pox infection. Another result, of a local character in the present case, has been brought to our notice—namely, in the Cricklade and Wootton Bassett Union, wherein the vaccination of children by the public vaccinator has fallen off so greatly as to have brought down the remuneration of one officer from £15 to 19s. 6d. in a half year. Even this modest sum was only earned at the cost of driving some fifty miles, and giving thirteen different stational attendances. This result is directly attributed to the non-reporting of the Vaccination Commission, and it is but a solitary example of what is happening in many parts of the country. Expert public vaccinators and painstaking vaccination officers all over the provinces, and in London too for the matter of that, are performing duties which hardly pay expenses, and all the time they see children escaping the law's requirements in a matter of prime importance to every individual, the vaccinated and unvaccinated alike. Each person permitted to violate the vaccination laws becomes a distinct danger to the community, and the Commission would seem to be incurring a great responsibility by their continued delay, having in view the ever-increasing tendency of Boards of Guardians and individuals to shelter themselves behind the fact of the non-appearance of the final report when shelving the matter of vaccination. The question has long ago passed out of the range of party politics, and has become one of national import. The country has much at stake, both from a health and financial point of view, as long as vaccination remains unenforced.

THE WEST HAM SCHOOLS.

THERE have been 29 cases of diphtheria, with 2 deaths, among the children in the West Ham schools. The schools also have been attacked by measles and German measles. The latter "developed seriously," and these diseases are to be attributed, in the opinion of the medical officer, "entirely to overcrowding." In spite of this opinion it was desired that more children should be admitted to the schools, but in the report of the medical officer he states with emphasis that he "will not even consent" to the further admission of children until the numbers were reduced to the proper standard as approved by the Local Government Board. He advocated that those children who were at present waiting in the workhouse to be admitted should be either boarded out or accommodated in temporary buildings, for it would be impossible to allow children again to enter the schools until at least two months had elapsed from the occurrence of the last case. A discussion followed the reading of the report, in which the usual ignorance of the guardians concerning the work they have undertaken was exhibited. One gentleman confused the Sheffield scheme of scattered homes with the Romford village community. The sole conclusion arrived at was a resolution to ask the Local Government Board to give the guardians "a free hand" to deal with the children as they thought proper, a request which the Local Government Board may very well think it advisable to refuse. A Board, composed of persons who are either too ignorant of elementary hygienic principles, or so indifferent to the welfare of the children under their care as to overcrowd them until they are debilitated by preventable diseases is not fit to have "a free hand" to guide or to control them in the future.

EDINBURGH AND LEITH ON THE HOSPITAL QUESTION.

THE First Division of the Court of Session on October 20th disposed of an appeal by the Corporation of Edinburgh against the judgment of the Leith Dean of Guild Court, refusing their petition for a warrant to erect a temporary hospital at Quarry Holess, Easter Road. The Edinburgh Corporation proposed to erect the hospital upon ground belonging to them as administrators of the Trinity Hospital, and in a report by William Benson, master of works, no objection

was taken to the proposed structures. The only respondent was John Welsh, solicitor, who raised questions of heritable right. The Dean of Guild Court (Ballie Archibald dissenting) refused the application, on the ground that the Edinburgh Corporation had no right to erect the hospital there, at all events, without the consent of the Town Council of Leith. The Division to-day recalled the Dean of Guild's judgment, and remitted back to the Dean of Guild to proceed with the application as should seem just, holding that the grounds upon which the Dean of Guild Court proceeded were not before them, and that that Court had no business to conjure up objections with which as a court they had nothing to do. It will be remembered that this matter came up at an adjourned meeting of the Leith Dean of Guild Court, when the Provost, who of late has been making himself conspicuous along several lines, intimated that there was no use discussing the matter—that he would not grant permission to Edinburgh for the proposed hospital under any circumstances. He has now been sharply taught that there are certain laws in existence for the guidance and control of persons like himself.

VIRCHOW ON PASTEUR.

AT a meeting of the Berlin Medical Society, held on October 16th, being the first since the recess, Professor Virchow, in speaking of the members who had died since they had last met, referred to the late M. Pasteur as the most eminent of them all. That Society, he said, had conferred its honorary membership on the departed French *savant* in 1892. Professor Virchow emphasized the universal importance of Pasteur's proof of the inadmissibility of the theory of autogenesis. Pasteur was not friendly to the German Empire, but that had not affected the Society's opinion of his merits. In order to understand his feeling towards the German Empire it was necessary to remember that he earned his first title to fame at Strasburg University, now a German seat of learning. Professor Virchow concluded by remarking that a final judgment as to the value of Pasteur's inoculations against hydrophobia was not yet possible, but it was already necessary to admit that it had formed the starting point of a new departure in medicine.

AN IRISH "CURE" FOR HYDROPHOBIA.

THE Newry Board of Guardians have again presented to a wondering world an example of the wrongheadedness which seems sometimes to seize upon public bodies. Three men presented themselves at a recent meeting of the Board, stating that they had been bitten by a rabid dog; and a report was read from Dr. Mills to the effect that he had made a *post-mortem* examination of the dog, and was satisfied that it had suffered from a very virulent form of the disease. The three men asked to be sent for treatment, and Drs. Beantch and Smartt recommended that they should be sent to the Pasteur Institute in Paris. According to the report in the *Belfast News Letter*, it was suggested by certain guardians that the men should be sent to "M'Govern of County Cavan," who, "it was stated would only charge about £8 for each person, whereas if they would send them to Paris it would cost the ratepayers £25 each." M'Govern, it may be remembered, is a man who professes to have inherited the secret of a sure cure for hydrophobia, and has been taken under the protection of certain persons who are in chronic opposition to any improvement in rational medicine founded on experimental research. The guardians decided to take the more economical course, and the men were given £1 apiece for expenses, and sent, along with a little girl who had also been bitten, to M'Govern of County Cavan. There has arisen since a complication which would be merely amusing if the matter were not in its nature so serious. It would appear that there are two M'Govern's in the field. At the last monthly meeting of the Board of Guardians two letters were read. One was from Philip

M'Govern, of Glan, co. Cavan, stating that he had treated the four patients, that he had sent them home "cured," and that he would make his charges very reasonable. The other was from John Laurence M'Govern, of Corroque, Down, co. Cavan, and in it he stated that he was the person who possessed the proper cure for hydrophobia, and that the four persons sent to him had been intercepted at Belcoo railway station, and taken to Philip M'Govern's house for treatment. The guardians, it was stated, had intended to patronise Laurence, but the men expressed themselves perfectly satisfied, and "the matter dropped" so far as the guardians are at present concerned. But it can hardly rest here. The clerk to the guardians made a most surprising statement as to the attitude of the Local Government Board in Ireland towards this pretended cure. He is reported to have stated that about four years ago the guardians sent four persons to M'Govern, and that the Local Government Board disallowed the expenses. M'Govern, however, sued the guardians and got a decree, and the Local Government Board finally gave way, and allowed the amount of M'Govern's bill, with costs, to be paid. It is to be hoped that on the present occasion the Local Government Board will show a little more backbone, as otherwise its deplorable concession of four years ago will be converted into a dangerous precedent.

THE REFORM OF GERMAN LUNATIC ASYLUMS.

THE need for reform in the administration of lunatic asylums and in the care of lunatics in Germany was the main topic of discussion at the meeting of the German Association of Alienists which met recently at Hamburg. A series of resolutions were adopted affirming that all institutions for the care of persons mentally unsound should be under the immediate direction and control of specially trained medical men, whether the inmates of such institutions were or were not supposed to be susceptible of cure. The desirability of giving special instruction in lunacy to medical students and requiring a more rigid examination in the subject was insisted on, as was also the necessity for diminishing the overcrowding which exists in many German asylums, especially in Prussia. In view of the popular indignation excited earlier in the present year by the laying bare of many crying abuses, it is believed that the present is an opportune moment for a strong expression of opinion by alienist physicians.

DIPHTHERIA IN LONDON.

OUR attention is drawn to the fact that in one fortnight the deaths from diphtheria have increased from 44 to 76 per week, and we are asked whether the total notifications have increased *pari passu* with the deaths, pointing out the bearing of such increase upon the question as to the utility of the serum treatment. The following are the figures in regard to diphtheria in the metropolis during the past six weeks:

	Week ending—					
	Sept. 21	Sept. 28	Oct. 5	Oct. 12	Oct. 19	Oct. 26
Total notifications	265	289	263	304	310	319
Total deaths	37	55	44	56	76	61
Admissions to Asylum						
Board Hospitals	113	111	87	100	114	113
Deaths in Asylum						
Board Hospitals						
cases admitted						
diphtheria	14	20	21	20	14	22

It will be seen from this that the fact of deaths from diphtheria having increased in one particular fortnight from 44 to 76 per week can hardly be taken as a complete presentation of the existing condition of affairs.

It is satisfactory to note that there was a decline last week in the mortality from diphtheria in London. The deaths referred to this disease in the metropolis, which had been 44, 56, and 76 in the three preceding weeks, fell to 61 during the week ending Saturday last, October 26th, but exceeded by 22 the average number in the corresponding week of the ten preceding years, 1885-94. Of the 61 deaths recorded last week, 39 were of children under five years of age, and 20 of young people aged between 5 and 20 years; while only 2 fatal cases occurred among persons aged upwards of 20 years. After distributing the deaths from diphtheria that were recorded in the Metropolitan Asylum Hospitals and other public institutions to the sanitary areas in which the patients had previously resided, it appears that 7 cases belonged to St. Pancras, 6 to Islington, 6 to Poplar, 6 to Greenwich, and 4 to Hammermith sanitary areas. The number of diphtheria patients under treatment in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 659 and 667 in the two preceding weeks, had further risen to 675 on Saturday last, October 26th; 115 new cases were admitted during the week, against 90, 102, and 115 in the three preceding weeks.

THE ISLINGTON INFIRMARY AND THE SICK POOR.

AT the meeting held on October 17th the attention of the Islington Board of Guardians was called to the serious nature of the overcrowding of the patients in the infirmary. From the statistics given it was made clear that there were at the present time 102 patients in excess of the certified number, and it must be noted that the winter is only approaching, and that when it does come this excess is sure to be increased. It will be remembered that the Local Government Board has repeatedly requested the Islington authorities to increase the infirmary accommodation, and that last year a site for the new building was actually bought at a heavy cost at Bowes Park. Since the date of the purchase nothing has been done, and the magnificent park has been left absolutely unused except for "treats" for the school children and guardians' "outings." In the meantime the poor suffer; the medical officers have had their work increased without any additional pay or assistance, and the largest and richest parish in the metropolis has still the smallest and most inadequate infirmary in proportion to the number of ratepayers in the district. This is most discredit to the guardians, and it behoves the Local Government Board to act with the necessary promptitude, and to enforce its legitimate demands, so repeatedly made and so constantly ignored. The present infirmary, with its 595 patients, has still only two medical officers without the assistance of even one clinical clerk or dresser. At the same meeting of the Board it was decided that the additional medical officer, so imperatively called for, should not be selected until the infirmary accommodation is completed. It is rather surprising to read in the report in the *Islington Gazette* that this resolution was carried on the motion of Dr. Jackson, a medical member of the Board. We can hardly realise that a medical man could formulate such a resolution in face of the undoubted fact that the excess of patients is so great. Even if there were only the certified number in the infirmary, namely, 493, the paucity of medical officers would still remain apparent. Overcrowding of patients in public infirmaries cannot be permitted, and the Local Government Board will no doubt see that its instructions and orders are carried out, as the present state of things is dangerous and discredit to the extreme.

PRESENTATION.—On retiring after twenty-two years' practice in Lee, Dr. Hutchins Williams was recently presented with a handsome centrepiece, goblets, peg cups, and fruit dishes in silver. Mrs. Williams was presented with a gold bracelet.

ROYAL COLLEGE OF PHYSICIANS.

THE ADMISSION OF WOMEN TO THE LICENTIATESHIP.

AN extraordinary Comitia of the College was held on Thursday, October 24th, Sir J. RUSSELL REYNOLDS, Bart., President, in the chair.

It was announced that on the recommendation of the headmaster of Epsom College the Jenks Memorial Scholarship had been awarded to Mr. Douglas Turner.

Communications were received from the Royal College of Surgeons, reporting the proceedings of the Council of that body, and inviting the Colleges to appoint delegates to confer with delegates from their own body on the question of altering the arrangements of the Five Years' scheme adopted in 1892, and with the approval of the College the President nominated Drs. Ord, Moore, Liveing, Cayley, Poore, and Taylor.

On the recommendation of the Treasurer it was decided to accede to the request of the headmaster of Westminster School, made through Dr. JOHN OGLE, for the loan for one evening only of the portrait of Sir Thomas Millington, in the possession of the College, and suspended in the hall.

The consideration of a petition from the officers and teachers of the London School of Medicine for Women, supported by many signatories, was then taken up.

Dr. CHARLES WEST, as the senior Fellow present, rose to oppose its acceptance, and after premising that the question had been debated in the College eighteen years previously, when a similar petition was rejected by 68 votes to 18, he proceeded to ask what were the motives which influenced women in wishing to enter the medical profession; the reply to this he found in an address by Mrs. Garrett Anderson, the Dean of their medical school, and the motives appeared to him to be quite unworthy. Up to 150 years ago one department, namely, that of midwifery, had been entirely in the hands of women, but they had done absolutely nothing to advance its practice, and it had been left to a man—Ambroise Paré—to introduce turning, whilst the invention of the forceps had been due also to a man—Chamberlen. In America women had practised medicine for fifty years, but he was not aware that they had made any contribution to our knowledge, and in the subject of children, which was supposed to be one for the study of which they were particularly adapted he had failed to find any contribution to practical medicine made by a woman. The admission of women to the medical profession was not a mere social change, it was a social revolution, and it did more than concern the dignity of the College, for it concerned society at large, and the position of women in that society. If women were admitted to the licence the other diplomas must also be open to them, and not only the offices in the College, but even the presidential chair. In conclusion, he moved that

The College having maturely considered the petition, declines to grant the prayer of the petitioners.

Sir JOSEPH FAYRE said that the question whether it was expedient to admit women to their diplomas was one that concerned the dignity, welfare, and prestige of the College, and he felt that to alter the constitution of the College in this way was a dangerous experiment. When a career was open to women in the Senate, at the Bar, and in the pulpit, he would be willing to reconsider his opinion, and not till then. In reference to the question of the usefulness in India of women doctors, without in any way denying what had been said in their behalf, he wished to say that up to twenty years ago, when he was in India, he had never known any instance where in a case of serious illness any difficulty had been placed in the way of a physician or surgeon entering a harem, and if he found it necessary the patient was always uncovered. By desiring to receive women he denied that they would be in any way persecuting them.

Sir B. W. RICHARDSON, after referring to former decisions of the College on other subjects, which he said time had shown to be gravely erroneous, hoped that the College would now accede to the petition, for he felt sure that the admission of women into the College would be certain to come to pass. He thought it was not consistent to exclude them at the bedside when they had all seen that the functions of the head of the State could be so eminently filled by one as by our pre-

sent Queen. As to the danger of one of the women occupying the Presidential chair, he thought, considering how few Presidents the College had, no notice need be taken of the argument.

Dr. HARE thought that this was an infinitely important subject. He admitted that women could acquire knowledge, but denied that they could create or advance it, and mentioned music and mathematics in support of his views. He quite agreed that we had had excellent Queens, but then they had men for their Ministers, and there was as yet no instance of a female Prime Minister.

Sir W. BROADBENT, who spoke as one of the petitioners, said there was no reason why we should deny to women the same lofty motives that we claimed for ourselves. Most of the speakers had addressed themselves to the question of the admission of women into the profession, which was not the point at issue, and he denied that the admission of women into the profession had proved to be a failure. If the College had governed well in regard to men it would do also for women, and he thought it would be well that they should be within the jurisdiction of the College. In regard to the question of their usefulness in India no one would say that the zenanas were open to ordinary practitioners, and there were thousands of women in India suffering for lack of proper medical advice. Women desired some higher status and recognition than the L.S.A., and it was a distinct disability to them not being able to get the licence of the College.

Dr. BARNES said that the medical education of women must necessarily be imperfect and incomplete, and that was a fundamental objection to them. As to practice in India, he said that great progress had been made in the last few years, and the natives in many parts were now following European practice.

Dr. DOUGLAS POWELL, whilst agreeing with all those who opposed the petition, urged that there was nothing in the practice of medicine that men could not do as well as or better than women. The profession was overstocked already, and to dilute it or further overstock it with women would only tend to cheapen and degrade it. The College was looked upon as a referee in questions of public health and many social questions, and he thought it would be a very grave thing for them to decide that it was advisable that women should enter the medical profession; the question had never been debated in a medical body possessed of such authority as the College. The duties of a woman lay in the household, and in bearing, rearing, and educating children.

Dr. PAYNE said that Dr. West and those who thought with him had used precisely the same arguments that were used in the discussion eighteen years previously, but in the interval the state of affairs had much changed, and the position of women now was very different to what it was then. The excess of women over men was something like one million, and in the middle and professional classes there was an ever increasing number who had to earn their own living; their entry into the professions was simply the result of economic laws forcing them on, and it was only natural that they should aim at some of the more remunerative callings. Even if we desired to discourage them from entering the profession we could not altogether prevent them, and he thought it was our duty to let be, and let those who were able to follow the practice of medicine do so.

Sir R. QUAIN gathered that the argument was that because there was a surplus of women they were to be shoved into the College, and he objected very strongly to it; the pulpit and the Bar were more fitted for their intellect than medicine. It seemed to him that men were becoming effeminate and women masculine.

The President, after referring to a letter from Sir William Jenner in opposition to the petition, said that in his judgment women were physically, mentally, and morally unfitted for the practice of medicine, and he thought that of all professions it was the one for which they were least fitted. He was told that in India there was now no difficulty as to medical men seeing patients in the zenanas in cases of illness.

A show of hands was then taken, and the President declared Dr. West's motion carried; a division having been demanded was taken with the following result: For the motion, 50; against, 50; majority, 2.

The Comitia was then dissolved.

We have been asked to publish the following letter, which was circulated among Fellows of the Royal College of Physicians shortly before the meeting reported above:

We the undersigned Fellows of the Royal College of Physicians of London, gravely impressed with the far-reaching importance of the question, now before the College, whether to admit women to its diplomas, desire to place on record our reasons against granting the prayer of the petition recently presented by the officers and teachers of the London School of Medicine for Women.

In common with a large body of medical men—probably a great majority—we hold, and always have held, that the admission of women to the medical profession is most undesirable; and, whilst fully admitting the ability of women to comply with more examinalional tests, we are none the less convinced that they are by nature unfitted for the pursuit and practice of the medical profession.

Although some holding this view have nevertheless deemed it both consistent and desirable not to oppose the admission of women, but have, on the contrary, given substantial aid to the attainment of that object, yet we see no reason to depart from our original carefully grounded objections, and while recognising with regret the action of other bodies, desire to offer all legitimate opposition to the same course being followed by the Royal College of Physicians.

We are unable to admit the force of the arguments urged in favour of the admission of women to the diplomas of the College, on the ground that other corporations and universities have admitted them, and we fail to perceive any reason why the Royal College of Physicians should be an exception. The number of universities and medical corporations of the United Kingdom which now admit women to their degrees or diplomas is sufficient to secure a full and complete trial of what at present is but an experiment—an experiment which another generation may show to be a mistake. In the metropolis itself the London University and the Apothecaries' Society open their doors to women, and thus offer ample opportunities for qualification.

To the argument that the admission of women to the College is "inevitable," we desire to offer the fullest resistance; believing that the principle is wrong, we refuse to submit to considerations of expediency, and regard it as a duty which we owe to the College, to the profession, and to the public at large to prevent, to the utmost of our ability, the Royal College of Physicians being made a portal to the obtaining of which our recent and judgment condemn.

On two points we have reason to believe considerable misconception exists. Inasmuch as the license of the College gives a title to proceed to the Membership, and that the Members are potential Fellows, it would be difficult if women were admitted to the lowest to exclude them from the higher diplomas. Those who support their admission must be prepared to admit them to the common and administration of the College, and to place the highest offices in the College within their reach.

It is also urged that, in view of the possibility of the Royal College becoming associated for examinalional purposes with a reconstituted London University, such a circumstance would of necessity compel the College to admit to its diplomas all candidates, irrespective of sex, in whose examination the College took a share. But this is not so. In all discussions in the College on the University question, the full power of the College to confer or withhold its diplomas by the vote of the Fellows, as at present (independently of the results of examination), has been fully reserved.

On the ground, therefore, of our objection on principle to the admission of women to the profession, and having regard to the extensive opportunities they already possess for obtaining a registrable qualification, we protest against this College, the most ancient and influential Medical Corporation in the kingdom, being forced into a position from which there would be no receding, and which could only be occupied with loss of dignity and prestige, in order to satisfy what we believe to be the improper demand of an inconsiderable minority.

October 22nd, 1895.

*—The foregoing statement has only been prepared within the last few days, and no extended attempt has been made to obtain signatures. The College officers have not been asked to sign.

The following is the text of the petition of the London School of Medicine for Women:

To the Registrar of the Royal College of Physicians of London.

Sir,—We the undersigned desire respectfully to petition the Royal College of Physicians of London to admit to its examinations and diplomas students of the London School of Medicine for Women.

A similar request was made many years ago to the Royal College of Surgeons of England, and refused; but we venture to hope for a different result upon the present occasion, when both Colleges will be approached. That request was made at a time when the admission of women to the medical profession was a question still *sub judice*. Doubts were then felt as to the effects which such a change would have upon the profession, and upon women themselves. Years have since passed; the main question has solved itself, and doubtful points have been settled by experience.

At the beginning of the present year there were over 200 women upon the Medical Register, of whom more than 150 had been educated at the London School of Medicine for Women. One after another Universities and Examining Boards have admitted women to their degrees and diplomas, so that few now remain closed. In the charters of recently

established Universities the right of women to a degree is recognised. Several medical schools for women have been opened in Scotland and Ireland, and the total number of women studying medicine has steadily increased. Many women, both in this country and abroad, hold appointments on the staff of hospitals for women and children; some of these hospitals are worked entirely by women, and cases of all kinds and of all degrees of severity are received. Public bodies, like the General Post Office, the Metropolitan Asylums Board, and various county councils, have appointed women as assistant medical officers in the institutions under their control.

The British Medical Association, the Medico-Psychological Association, the Society of Anaesthetists, and the Association of Medical Officers of Great Britain admit women as members. To start, the reception of women into the profession is going on steadily, and experience has proved that these eyes have not realised when it was feared would follow the admission of women to the study and practice of medicine, and that there was a demand for women as medical practitioners.

The London School of Medicine for Women has a number of its books 150 students. The results of its teaching, as shown by the position taken by its students in public examinations, are excellent. The biological, chemical, and physiological laboratories are adequate, though the Council desire to improve them, and are raising a fund for rebuilding the school. The Royal Free Hospital, to which students of the London School of Medicine for Women come as students, provides ample clinical opportunities, and the teaching of the staff is organised upon the same basis.

We therefore submit that the London School of Medicine for Women, with the Royal Free Hospital, is worthy of recognition by the Royal College of Physicians of London. The admission of women to the medical profession is a source of serious inconvenience and loss to the school and to the students. It is almost of taking a diploma from a College of Physicians or Surgeons the students are compelled to travel to Ireland or Scotland, and thus incur unnecessary expense and fatigue in connection with their examinations.

On the above grounds, we earnestly hope that the Royal College of Physicians of London will accede to our petition, and will open its examinations to the students of the London School of Medicine for Women.—We are, sir, your obedient servants,

The following signatures will be found attached to the petition from the London School of Medicine for Women:

Elizabeth Garrett Anderson, M.D., Dean and Lecturer on Medicine.
Julia Cook, M.D., L.R.C.P.I., and L.M., L.R.C.S.E., Sub-Dean.
A. T. Norton, F.R.C.S., Treasurer and Lecturer on Surgery.
Isabel Thorne, Honorary Secretary.
Sir Gainsford Bruce, Chairman of the Committee of the Royal Free Hospital.
Charles Burt, Chairman of the Weekly Board of the Royal Free Hospital.

ROYAL FREE HOSPITAL STAFF.

E. W. Boughton, M.D., B.S., F.R.C.S.
LECTURERS AT THE LONDON SCHOOL OF MEDICINE FOR WOMEN.
Stanley Boyd, M.B., B.S., F.R.C.S., Lecturer on Anatomy.
H. B. Donkin, M.D., F.R.C.P., Lecturer on Medicine.
Mary L. Dowson, L.R.C.P.I., L.R.C.S.I., Lecturer on Forensic Medicine.
A. Dupré, F.R.S., F.R.C., Lecturer on Toxicology.
W. D. Halliburton, M.D., F.R.C.P., F.R.S., Lecturer on Physiology.
Charles Mercer, F.R.C.S., Lecturer on Mental Pathology.
Mary A. D. Scharlieb, M.D., B.S., Lecturer on Midwifery and Gynaecology.
A. Quarry Silcock, M.D., B.S., F.R.C.S., Lecturer on Pathology.
Sir William H. Broadbent, Bart., T. Lauder Brunton, M.D., D.Sc., M.D., F.R.C.P.
Sir James Paget, Bart., F.R.C.S. Thomas Ross, M.B., B.S., F.R.C.P.
Sir Henry Acland, Bart., K.C.B., F.R.C.P. Charles J. Cullingworth, M.D., F.R.C.P.
Sir Thomas Crawford, K.C.B., M.D., F.R.C.P., F.R.C.S. W. R. Gowers, M.D., F.R.C.P., F.R.S.
Sir Alfred Grant, M.D., F.R.C.P., F.R.S. Victor Horsley, F.R.C.S., F.R.S.
Sir Henry Thompson, F.R.C.S. Stephen Mackenzie, M.D., F.R.C.P.
Sir William Roberts, M.D., F.R.C.P., F.R.S. Frederick Treves, F.R.C.S.
Sir Spencer Wells, Bart., M.D., F.R.C.S. J. Knowles Thompson, M.B., C.M.
Samuel Wilks, M.D., F.R.C.P., F.R.S. K. A. Winter, F.R.S.
J. Hughlings Jackson, M.D., F.R.C.P., F.R.S. Augusta Waller, M.D., F.R.S.
Thomas Buzzard, M.D., F.R.C.P. Percy Yeo.
H. Charlton Bastian, M.D., F.R.C.P., F.R.S. Richard Barwell, F.R.C.S.
Thomas Barlow, M.D., F.R.C.P., F.R.S. Herbert W. Page, M.B., F.R.C.S.
W. Orange, C.B., M.D., F.R.C.P. John H. Gallou, M.D.
Frederick T. Roberts, M.D., F.R.C.P., F.R.S.
Jonathan Hutchinson, M.D., F.R.C.S., F.R.S.
E. Ray Lankester, M.A., LL.D., F.R.S.

It appears from statistics published recently that the medical faculties of the German Universities contain more students than any other. There are 8,361 students of medicine, 8,132 of law, 7,619 of philosophy, and 4,597 of theology. The University with the largest number of students in all faculties is that of Berlin with 4,265, next comes Munich, then Leipzig, and then Bonn. The University with the largest proportion of medical students is Warzburg.

REPORTS

ON

THE NURSING AND ADMINISTRATION
OF IRISH WORKHOUSES
AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

VI.—CLONES UNION, CO. MONAGHAN.

THIS is a second class house, but as is the case with so many workhouses it is more than half empty; the number all told on the day when we made application to go over the house was only 80, and we were informed that of late years the number of inmates had not exceeded 100; of these 80 inmates more than half are either helpless or children. The union stands close to the town of the same name.

THE INFIRMARY.

to which part of the house we directed our steps first, is a two-storeyed building stated to hold 40 beds, and has an average of 25 patients under treatment. Structurally it compares favourably with other houses lately visited; the walls have a smooth surface, a dado of grey colour is painted behind the beds for about 4 feet from the floor, the rest being white-washed, the ceilings and pitched roof are plastered and white-washed. Here, however, the improvement ends; the windows are small and ill-fitting, placed on one side only; small square apertures in the opposite wall do duty for windows, the fireplaces are old and inadequate, and the wards generally destitute of comforts for the patients. The wards occupy both floors, but that for males on the first floor was in the hands of the workmen, consequently that on the lower floor was more crowded than usual. Small wards for isolation have been taken off the ground-floor wards; they are cell-like structures, holding 1 or 2 beds; indeed, they appear to have been the idiots' quarters before a door was opened in the party wall. This construction makes the whole ward practically one, hence the use of these wards for isolation must be very limited. We found the same arrangement on the female side. The narrow beds are used throughout the infirmary, with straw ticks and pillows. We were informed that some hair mattresses are ordered for use on these frames, but the introduction of the hair mattress on this old frame will not add to the width or the length. Between the beds is a tier of shelves divided in the middle to hold mug, medicine bottle, or personal possessions; there were a few arm-chairs for the patients, and the inevitable bench.

THE PATIENTS

also in their appearance and in that of their beds contrasted favourably with some houses we had visited; they looked cleaner and more tidy, but when we went into detail we found the nursing was sufficient neither in quantity nor quality. The one nurse is untrained, and she has for assistance mostly women with illegitimate children; these pauper nurses are described by the medical officer in his report to the guardians "as ignorant and indifferent;" there is no night nurse, and, to quote from the same authority, "the patients on the male side are locked up without a light, and with such help as a fellow patient can render them." On the female side, also, the wards are left without a light through the night; the only light for the long winter evenings in the wards is a paraffin lamp. As we walked through the wards we noticed a case of fracture of the neck of the femur, fracture of the radius, cystitis, rheumatism, a burn—the patient having fallen into the fire in a fit—bronchitis, phthisis, and other chronic cases; an unruly man, a case of rheumatism, was placed apart in the small room by the stairs called the day room. From this list our readers will see that there are several patients requiring skilled nursing; one would rather not think too minutely of their condition.

LOCKED UP AT NIGHT IN THE DARK, dependent on each other for assistance, say to the fractured femur or the rheumatic patient. We noticed, in traversing

the wards, some utensils left unemptied by the beds, and, as the wards are locked during the night, the pails and buckets must remain so until the morning. The patients have no change from the wards, nor have the wards any relief from the patients, as there are no day rooms, but such as are taken for other purposes, and, even if not so appropriated, they are hardly suitable for use by sick or convalescents, being dreary, dark, and bare. That on the female side has a flagged floor, and is made use of as

THE INFIRMARY KITCHEN.

Here the cooking is done by the nurse, or, to speak more accurately, by an inmate under her supervision. There is no range, simply an open wide mouthed fireplace, and the kitchen was very bare of cooking utensils, or of the means of serving the food to the patients. The diet consists principally of milk, bread, tea, and broth. We were glad to see that the day's supply of milk was kept in a cupboard, and the bread in a box in the kitchen. The deficiency in the kitchen is in process of being remedied, as we read in the last report that the guardians have authorised the placing of a range in this little kitchen, and the providing of cooking utensils, plates, knives and forks. We are sure that this step on the part of the guardians will soon repay itself in greater economy in the preparation of the food and its distribution, both sources of great waste in these institutions.

THE FEVER HOSPITAL.

has not been occupied for several years, and it is entirely dismantled. It is of the usual construction, and has its kitchen and laundry, with separate apartments for the nurse.

THE INFIRM WARDS

provide accommodation for about 18 men and the same number of women, and are situated in the wings of the body of the house; they were not more than half full when we saw them. The men were all out either at work or in the yard. The women, of whom about 6 are feeble-minded, were in their ward, under the charge of one of their number, who, as we entered the ward, was scolding and arguing with one of the feeble-minded in a loud, angry voice, justly drawing on herself the correction of the matron; but, as we noted the incident, we saw how unfit this inmate was to be placed in authority over helpless or imbecile paupers. The wards are badly lighted and ventilated, having one window at each end of a long room. The walls are rough and white-washed, unrelieved by pictures or colouring, open rafters, narrow beds down each side, benches, one old fireplace, and evidence of the one paraffin lamp during the dark winter evenings. We saw one basin, over which hung a roller towel for common use, changed, so we were informed, twice a week. The men have a boarded floor dayroom adjoining the ward; that for the females has been appropriated to the nursery, and, by order of the authorities, the old women may not go into this day room.

THE NURSERY.

a flagged room, large, dark, and unfurnished, was tenanted by a mother and her child. A room adjacent is the maternity ward. It is quite small, holding one bed for the patient and another for the pauper in attendance on the confinement; the confinements average from six to eight in the year. The dormitory over the nursery is appropriated to the nursing mothers.

THE LAUNDRY

is rather better found in the way of apparatus; we saw a wringer and a mangle; but the drying room requires enlargement and ventilation. A disused Turkish bath, or rather hot-air bath, has been turned into a drying room, in which is placed a small ironing stove; it has no ventilation or outlet for the steam, so that the clothes dry very slowly, nor is the space nearly large enough for the number of clothes that pass through the laundry. The workhouse kitchen exhibits the primitive arrangements of a past date; the copper are practically of no use, having been superseded by a stove and a portable cauldron which, at the present time suffices for the simple diets of the inmates.

BATHS AND WATER SUPPLY

are non-existent; there is no movable bath for the hospital,

which when required can be filled and emptied by hand labour only. No water is laid on, either hot or cold; there are no indoor conveniences, and those outside are privies, on the waggon system; the absence of indoor closets involves the insanitary practice of using open pails and buckets. In the body of the house there is a fixed bath for the children's use with a cold water supply only. As we were passing through the yards to see the outside places, we noticed that most of the airing courts were overgrown with rank grass, and that no seats were provided for use out of doors.

RECOMMENDATIONS.

It is evident that the two improvements most urgently required are in the nursing of the patients and the provision of healthy sanitary appliances, and to these points we should endeavour to draw the attention of the guardians; but when we turn to the report of the medical officer placed before his Board in obedience to the instruction of the Local Government Board, we read that the committee appointed to inquire into the condition of the hospital "would not recommend any alteration in the system of nursing or the sanitary arrangements." This Board, then, must be left to the central authority, and we trust that the sword of vengeance will soon fall.

THE BANBRIDGE BOARD: THE MEDICAL OFFICER AND THE PRESS.

This Board has been living in a fool's paradise, out of which it has been rudely shaken by the action of its medical officer, and now that it finds itself exposed to the trenchant criticism of an independent public, and that the "model workhouse" with its "model Board" is classed among such no-er-do-wells as (say) Cootahill, for instance, it is lashing its sides with fury. Dr. Hawthorne made a report on the state of the workhouse, in obedience to the mandate of the Local Government Board. That report was published in the *Banbridge Chronicle*, and "a Dr. Moorhead" has had the audacity to place this report before "a Medical Officers' Association," and from that report to class this model house among the "worst class." In this report we read that "the wardens and women are all paupers, the latter having illegitimate children, and in many cases are most undesirable and inefficient in attending to the comfort and helping in the nursing of the sick. The male wardens are all old and infirm patients in most cases, too infirm to discharge the duties required of them. The narrow beds, as described in Sir Philip Smyly's letter, are still in use in the lunatic wards, the upper wards of the infirmary, the children's wards, and the fever hospital; pails and buckets take the place of night conveniences; there are no knives, plates, or forks in use throughout the house. The food is good, well cooked, but badly served. The ventilation is bad." Dr. Hawthorne apologises for the mischief he has done, but we leave our readers to judge with whom the truth lies. We are sorry for the affliction that has overtaken this model Board, and we would advise them to keep their proceedings from coming before the public in future.

THE SIXTH ITALIAN CONGRESS OF INTERNAL MEDICINE.

Professor Baccelli's Presidential Address.—The Serotherapy of Tuberculosis.—The Next Congress.

The Sixth Congress of Internal Medicine was opened in Rome on October 22nd, under the presidency of Professor Baccelli. There was a large attendance of members of the profession from various parts of Italy.

Professor BACCELLI in his opening address, after some introductory remarks, went on to speak of the great problems of etiology, which no longer included only the morphological appearances of the pathogenic micro organisms, but the study of toxic products. From pathology to the double sphere of practical medicine, and from the latter to the former motion was perennial, continuous. Intuition, however, and the conviction of new truths frequently appeared to the eyes of the clinician long before the laboratory furnished experimental proofs. The latest studies in Italy attested the truth of this. The scientific movement of the present time was most intense around the treatment of infectious diseases, and sero-therapeutics held the place of honour. The therapeutic concept of Behring was justified by the results, but the critical judgment even here clipped the wings of an ill advised enthusiasm. Serotherapeutics in diphtheria now constituted the method which numbered the greatest successes. To-day through the labours of one of their colleagues, sero-therapeutics was proposed also in tuberculosis. In the later times Italian labours in other provinces of pathology, especially in the nervous system, were creditable alike to the authors and to their country. While respecting all, they must not allow

the scientific world to maintain that those new truths which had their birth in Italy had been discovered elsewhere. One of them had demonstrated some years ago to Naunyn that the views expressed by him as to the murmur in the diseased heart had already been taught by an Italian clinician. To-day the same statement might be repeated in reference to some late French works attesting as theirs the lines of propagation of mitral murmurs (especially insufficiency) which for thirty years had been taught and published in Italy. The address was much applauded.

A discussion on Serotherapeutics was then opened by Professor FOÀ, Director of the Anatomico-Pathological Institute of Turin. After referring to his own investigations and to those of others, he summarised the present condition of the subject. Hitherto the most certain and efficacious results had been from toxic infections; the latest researches, however, showed the possibility of obtaining effects quite as certain in septic infections. The concept that every infection reduced itself to a pure poisoning, and that every reaction consisted in the production of the counter-poison, was, perhaps, too absolute. In the case of diphtheria, serumtherapy had issued triumphant from the test of practice, and statistics showed the sensible diminution of the mortality obtained by the new treatment. Serumtherapy had been less efficacious in acute cases of tetanus. The tetanic manifestations in such cases would indicate grave organic lesions already complete, against which serumtherapy did not prevail; it was, however, the best preventive remedy. In typhoid and cholera serumtherapy had not found any application up to now. The grave difficulty probably depends on the notable difference existing between the experimental results and the natural condition of the infections in man. The latest researches of FOÀ have solved the problem of sero-therapeutics in diplococcal infection of the rabbit; it remains to study the problem in the larger animals, which allowed the results to be applied to man. Serumtherapy must not be allowed to hinder the development of prophylaxis. Both aimed at the prevention of diseases, and serumtherapy, where it shows itself in preventive immunisation, became a prophylactic measure.

Professor MARAGLIANO, Director of the Institute of Clinical Medicine, Genoa, followed. He referred to his researches on tuberculosis. He said he had clearly explained the materials he used in the vaccinations, and he summarised the new results obtained with his treatment by many Italian and foreign physicians. A total of 215 cases had up to now been reported. The treatment was used in cases of most diverse character, and all confirmed the value of the treatment. He concluded his address with the following propositions: 1. Therapeutic serums, to develop their special action, require the active concurrence of the affected organism. 2. The value of serumtherapy can be determined only by clinical observation. 3. Serumtherapy can develop its special action as much in acute as in chronic infections. 4. The therapeutical serums introduced up to the present in practice in Europe are absolutely innocuous. 5. Serumtherapy in its clinical application has up to now given indeterminate results in streptococcal and typhoid infections, doubtful in tetanus, promising in pneumonia, which awaits only a methodical clinical consecration; positive in tuberculosis, which only wants the confirmation of an extensive trial; incontestable and surely triumphant in diphtheria.

A discussion on the Retardation of Nutrition was opened by Professors DE RENZI and REALE of Naples. An interesting discussion followed in which Professors BIANCHI, DEVOTO, DE DOMINICIS, etc., took part.

Several other important papers were read at the Congress, but exigencies of space prevent our giving even the titles or the names of the authors. The Congress came to a close on October 25th after a vote of thanks to Professor Baccelli. It was decided that the next Congress should be held in Rome in October, 1896, and the following officers were elected: Professor Baccelli, President; Professors Muri and De Renzi, Vice-Presidents; Professor Maragliano, Organising Secretary; and Professor Rossoni, Treasurer.

It was the general opinion that this Congress was the most successful that has yet been held. The only disappointment in connection with it was that Professor Maragliano had not explained his method of obtaining the antituberculous serum, as many of the members had expected he would do.

THE "DAILY CHRONICLE" AND THE PRISONS.

IN the BRITISH MEDICAL JOURNAL of October 5th we remarked that "nothing comes out more clearly in the recently issued Blue Book of evidence taken by the Departmental Committee on Prisons than the failure of certain noisy and neurotic critics to prove their charges of maladministration against the prison authorities." We added that "our prison system rests entirely on Acts of Parliament which have been passed for the guidance of prison authorities; and the evidence from beginning to end proves that the Commissioners of Prisons have administered these Acts with loyalty and fidelity, and that the transfer of the prisons to Government has been to the public advantage in the way of economy, uniformity of discipline, and improved sanitation, while it has distinctly tended at the same time to the advantage of the prisoners themselves." It is admitted by the Committee that the direct gains to the community in economy and improved sanitation, as reflected in the reduced death-rate, would of themselves have sufficiently justified the changes made in 1877. This being the case, we much regret that the *Daily Chronicle* should repeat its misrepresentations, and should persist in its attempt to mislead the public on so important a subject as the administration of our prisons.

What may be its motive we do not know, but it is evident that our contemporary wishes to induce the public to believe that the rate of insanity in English prisons is abnormally high, and that this rate of insanity is due to ill-treatment of prisoners. In its issue of October 28th the *Daily Chronicle* states that, according to the Prisons Committee, the insanity is produced "by the very low and distasteful dietary to which habitual petty offenders are almost continually subjected." We have diligently searched through the report of the Committee, but have failed to find any statement of this character. We have found, however, a statement of a very opposite purport and drift at page 33 of the Committee's report, par. 92. It is to the effect that it is "inevitable" that the ratio of insanity should be greater in prison than outside. The Committee add that "the average prisoner in height, weight, strength, and mental condition is markedly below the average of the outside population."

The population of the prisons is a fluctuating population, which is in a state of perpetual change, and is renewed about thirteen times every twelve months. At every local prison fresh prisoners are constantly arriving, some of whom are lunatic. The sane prisoners are discharged on expiration of sentence, while those who are unsound in mind are sent to asylums. What possible benefit or advantage of any kind can be derived from comparing a fluctuating population of this character with a population which is stationary, or from attempting to deduce that the prisoners who are insane on their admission (and who are speedily certified as such) become insane after admission as the result of inhuman treatment? In making these reckless statements the *Daily Chronicle* is bringing a serious charge against the medical officers of prisons, many of whom are leading practitioners in the towns in which the prisons are situated. The medical officer of every prison possesses powers of interference transcended only by those of the Secretary of State, and if there is a particle of truth in the statements of the *Daily Chronicle*, every medical officer must have seriously neglected his duty. We shall prefer to believe that a humane, accomplished, and high-minded body of men have faithfully fulfilled their obligations, until we meet with some reason to the contrary much stronger than anything yet adduced.

With regard to the death-rate, we have referred to the annual report of the Medical Inspector of Prisons for the year ended March 31st last, and can find nothing in the smallest degree to justify the *Daily Chronicle* in stating that this report is "misleading and fallacious." The facts are given in the plainest manner, and we have seldom seen any return more complete than that which gives the particulars of the death of each prisoner who died during the year (Appendix No. 12). The number of deaths from natural causes in the local prisons of England and Wales was 109, or 7.6 per 1,000 of the average daily population. Thirty-four prisoners were released on medical grounds, exclusive of pregnancy, or at the rate of 2.3 per 1,000. Not reckoning all the releases on

medical grounds as deaths, and adding them to the actual deaths, the mortality for the year was 9.9 per 1,000. Ninety prisoners died during the first five months of imprisonment, and 5 died who were in or had just passed through the sixth month, making a total of 95 who died during the first six months of imprisonment. As the total number of deaths from natural causes was 109, it follows that only 14 died during the period following the sixth month.

With these facts before us we cannot but regret the attempts of our contemporary to throw odium upon the administration of an important public department. The inmates of our prisons are subjects of constant solicitude from the moment of their admission to that of their liberation; they are provided with many comforts, and receive a diet that would be considered luxurious by many a free labourer. If they fall ill they are admitted into hospital, where they have the benefit of skilful medical attendance, and enjoy "medical comforts" and delicacies in profusion which would be quite out of their reach in their own homes. Public servants are, of course, always open to fair criticism, but the attack made in this instance appears to be quite unfounded.

THE OPENING OF THE GLASGOW MEDICAL SCHOOLS.

WORK at the Glasgow medical schools was begun last week. Formal openings of any special kind are not the fashion in Glasgow, or indeed in any of the Scottish schools. In this, as in many other respects, it is the University that sets the fashion. Until the recent changes by the University Commissioners, the session at the medical classes began a week or ten days sooner than that of the other faculties, so that the formal opening of the University session did not occur till after the medical session was well under way. The medical classes were, therefore, allowed to begin their work quietly, any public trumpeting being obviously improper before the dignified solemnity of the public opening of the University by the Chancellor or Vice-Chancellor had occurred. The extramural schools have not thought it necessary to take advantage of this situation by providing any brilliant oratorical opening of their session, and have contented themselves with a semi-public opening by one of the staff in turn. Some of the professors or lecturers take the opportunity of the opening day of the class to give an address on a subject outside the exact limits of their own commission, but even in this there is no uniformity. Last week, for instance, Professor Joseph Coats opened his class of pathology with an address on Ludwig and Pasteur, and Professor Napier opened the session at St. Mungo's College with an address on "The Senses."

ROYAL NATIONAL PENSION FUND FOR NURSES.

A THIRD GIFT OF £22,500 TO THE DONATION BONUS FUND.

WE have the pleasure to announce that Her Royal Highness the Princess of Wales, as President of this Fund, was welcomed home on her return from Denmark on Saturday, October 26th, by a third gift of £22,500 for her nurses, as follows below, making the Donation Bonus Fund of this Society upwards of £97,000, in addition to the £11,175 standing to the credit of the Janina S. Morgan Benevolent Fund. This further sum of £22,500 has been subscribed since the Princess of Wales received the third and fourth thousand nurses at Marlborough House at the end of July.

It is the aim of the Princess of Wales Pension Fund for Nurses to encourage every nurse in the British Empire to save each year, if possible, from one-eighth to one-sixth of her earnings, as a provision against sickness, old age, and incapacity for work. Full inquiries and a careful estimate of all the circumstances of the case have convinced the Council that no member should receive sick pay or a pension of less than 10s. per week when she becomes incapable for work from any cause. Anyone may, however, join for an annuity of any amount. In the hope of placing all nurses in a position to secure the minimum provision, it is necessary to add £30,000 to the credit of the Donation Bonus Fund for every 1,000

nurses who join the Society. When 5,000 nurses have become members, and the Donation Bonus Fund amounts to £100,000, it is believed that the compound interest that will accumulate during (say) each twenty-five years will suffice to provide for every nurse of each series 10s. a week, with the aid of her own contributions. If this prove true, and whenever this occurs, the capital sum of £20,000 will be freed for the benefit of the next successive 1,000 nurses. In other words, with £100,000 in hand the fund ought to work automatically, or nearly so. These calculations may, however, be upset by the great popularity of the Pension Fund, for nurses are joining in such large numbers that the new policies issued in the first three weeks of the present month amounted to no fewer than 103. Up to this date the money contributed to the Donation Bonus Fund has come almost entirely from the merchant princes of the City of London, the general public, who owe so much to nurses, having so far contributed almost nothing. No appeal for funds has been nor ever can be made for this fund, but everybody has an opportunity of spontaneously contributing through the Society's bankers—the Bank of England.

The following is a list of the donors of the £22,500 completed this week:

	£	s.	d.
Mr. J. B. Robinson	5,000
Messrs. Wernher, Beit, and Co.	5,000
Mr. Walter H. Burne (a further)	2,000
Lord Iveagh	2,000
Mr. J. Pierpont Morgan (a further)	2,000
Messrs. N. M. Rothschild and Sons (a further)	1,500
Mr. D. Marks	1,500
Messrs. Marks, Bullock, and Co.	1,500
Mr. E. A. Hambro (a further)	1,000
Messrs. L. Hirsch and Co.	1,000
Messrs. Ansell, Mankiewicz, and Tallerman	1,000
Mr. E. Cassel	1,000
Mr. Robert Gordon (a further)	1,000
Mr. G. Bullock	1,000
The Hon. Egmont	1,000
Mr. E. Rawlings (a further)	1,000
Mr. C. Morrison (a further)	1,000
Mr. H. L. Raphael	1,000
Mr. D. J. MacRae	1,000
Messrs. De la Bere, Bellair, and Partners	1,000
Messrs. Hyam Brothers	1,000
Mr. Carl Hanau	1,000
Mr. Harry Pearson	1,000
The Duke of Northumberland	1,000
Mr. Jeffery Whitehead	1,000

£22,500

LITERARY NOTES.

It is stated that a biography of Professor Huxley is being prepared by his son, Mr. Leonard Huxley, who will be greatly obliged if those who possess letters or documents of interest will send them to him at Charterhouse, Godalming. They will be carefully returned after being copied.

An article on Louis Pasteur, by Dr. Sims Woodhead, appears in the November number of *Science Progress*.

A new periodical, issued by the United States Weather Bureau and entitled *Climate and Health*, has recently appeared. It is edited by Dr. W. F. R. Phillips, under the direction of Professor W. L. Moore, the new chief of the Weather Bureau, and, as its name imports, it is devoted to climatology in relation to health and disease. By showing the statistics of mortality and morbidity side by side with those of climate, it is hoped that new facts as to connections between sickness and weather changes may be discovered.

Mr. W. B. Saunders, of Philadelphia, announces the appearance on January 1st, 1896, of an *American Yearbook of Medicine and Surgery*, which he intends thenceforward to publish yearly. The book is to be edited by Dr. George M. Gould, with the assistance of a competent staff. It is the special purpose of the editor, as indicated in the prospectus, not only to review the contributions to American journals, but also the methods and discoveries reported in the leading medical journals of Europe, thus making the work "characteristically international." A feature of the book is to be an abundance of original and selected illustrations.

Mr. James Couldrey, of Seunthorpe, near Doncaster, writes to point out that the words, "He giveth his beloved sleep," quoted in Huxley's epitaph, are from the 137th Psalm, and in the New Version they read, "Giveth unto his beloved sleep,"

with a marginal note "or 'in sleep.'" This phrase, according to Mr. Couldrey, has a totally different meaning from that which the writer of the epitaph intended.

Mr. George Wherry, Surgeon to Addenbrooke's Hospital, in an "Alpine Letter," published in a recent issue of the *Cambridge Chronicle*, calls attention to the fact that a Swiss guide can go face forward and walk forward on a slope, while the amateur following has to go on his toes or turn sideways at the steep part. The explanation of this is not quite clear. Probably it is largely a matter of balance, but, as Mr. Wherry suggests, there may be some loss of mobility in the ankle of the guide accustomed to climb from a very early age. To throw light upon the point, Mr. Wherry induced Captain Abney to take photographs of guides in the act of climbing a rock. These, when compared with similar photographs of an amateur, may throw light on this curious bit of physiology.

Messrs. Kegan Paul, Trench, Trübner and Co. will issue in November the first number of a new series of the *Popular Science Monthly*. This periodical is edited by Professor William Jay Youmans, who established it more than twenty years ago. It records all scientific facts and discoveries as they present themselves, and is a register of all scientific developments. It strikes us as a happy thought on the part of the publishers to introduce to European readers a magazine which has been so long known and appreciated in America.

The sixteenth and final volume of the first series of the *Index Catalogue* of the library of the Surgeon-General's Office of the United States Army has recently been published. It includes 12,759 author titles, representing 4,897 volumes and 11,613 pamphlets. It also contains 8,512 subject titles of separate books and 13,280 titles of articles and periodicals. Owing to the large increase in the library since the publication of the *Index* was begun a second series is needed and the manuscript has been prepared; it will probably make five volumes of the same size and style as those already published. It is stated that the present volume is probably the last that will be issued under the personal supervision of Dr. John S. Billings. The Surgeon-General's library now contains 116,847 books and 191,598 pamphlets, practically all of which have been obtained in the course of the last thirty-five years, while at least one-sixth of the whole have been presented either in exchange or as free gifts to the library.

The *Medical and Surgical Reporter*, which recently migrated from Philadelphia to New York, has apparently not found that city favourable to its journalistic health. At any rate after a very brief stay there it has returned to its native place, where it will be edited by Dr. Harold H. Kynett.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

At the annual general meeting of the Royal Academy of Medicine in Ireland, held on October 25th, in the Royal College of Physicians, Dublin, the following officers were elected for the year 1896: *President*: James Little. *General Secretary*: William Thomson. *Secretary for Foreign Correspondence*: J. W. Moore.

MEDICAL SECTION.—*President*: T. W. Greaves. *Council*: J. Hawtrey Benson, J. Craig, H. O. Drury, E. A. Hayes, A. Montgomery, J. O'Carroll, A. R. Parsons, J. M. Richmond, W. G. Smith, H. C. Tweedy.

SURGICAL SECTION.—*President*: Sir Thornley Stoker. *Council*: C. B. Ball, E. H. Bennett, A. Chance, H. Fitzgibbon, Kendal Franks, E. Hamilton, F. T. Houston, J. Lentsaigne, A. Meldon, Sir Wm. Stokes.

SECTION OF OBSTETRICS.—*President*: Lombe Athill. *Council*: G. Cole-Baker, R. El. Fleming, Robert A. Flynn, J. H. Glenn, A. J. Horne, F. W. Kidd, J. L. Lane, A. V. Macan, R. D. Purfoy, A. J. Smith.

SECTION OF PATHOLOGY.—*President*: Connolly Norman. *Council*: A. H. Benson, H. Bewley, Edmund J. M. Weeney, J. O'Carroll, A. C. O'Sullivan, A. R. Parsons, R. Glasgow Paterson, J. M. Purser, J. A. Scott, J. E. Story.

SECTION OF ANATOMY AND PHYSIOLOGY.—*President*: John Symington (Belfast). *Council*: A. Birmingham, D. J. Coffey, D. J. Cunningham, H. C. Earl, Alec Fraser, E. H. Gault.

SECTION OF STATE MEDICINE.—*President*: J. M. Richmond. *Council*: E. Macdowell Cosgrave, Thomas Donnelly, Ninian Falkiner, D. Edgar Flinn, J. W. Moore, H. C. Tweedy.

THE LANCHESTER CASE.

DR. BLANDFORD'S CERTIFICATE.

Dr. G. FIELDING BLANDFORD has favoured us with the following statement: "I was asked by Mr. Lancheater and two of his sons if I would see his daughter on the following morning, and was told that she intended to go at once and live in illicit intercourse with a man in a station of life much below her own. They said that they thought she was not in her right mind. I went to the house as arranged, and with two of her brothers visited Miss Lancheater, who was at breakfast. Her brothers questioned her as to her intention of living with the man. She declared that she would do so, that it was right to do so, and in answer to a question said she would not marry him, even if he would marry her. She could give no reason for this conduct beyond saying that marriage was immoral. How it was she did not explain. She also said that if she married she should lose her independence. I pointed out that if she had children and was deserted she would have very little independence, but she only replied that he would not desert her. She could, she said, earn her own livelihood if he did. I reminded her that if she had the encumbrance of a family she would not be able to do this. Something was said at the end of the interview about a community of goods, and she explained her views on this. The interview lasted half an hour. I came to the conclusion that Miss Lancheater was of unsound mind for these reasons: I was informed that there was insanity in her family, her grandmother and an uncle having been insane; that she had always been eccentric, and had lately taken up with Socialists of the most advanced order. She seemed quite unable to see that the step she was about to take meant utter ruin. If she had said that she contemplated suicide a certificate could have been signed without question; I considered I was equally justified in signing one when she expressed her determination to commit this social suicide. She had a monomania on the subject of marriage, and I believed that her brain had been turned by Socialist meetings and writings, and that she was quite unfit to take care of herself."

The following is the form of statement which it is necessary should be filled up in urgency cases:

53 Vict. c. 5—Form 2.

(STATEMENT ACCOMPANYING URGENCY ORDER.)

I certify that it is expedient for the welfare of the said _____

—(or for the public safety, as the

case may be) that the said _____

should be forthwith placed under care and treatment.

My reasons for this conclusion are as follows: _____

4. The said _____
appeared to me to be (or not to be) in a condition of bodily health to be removed to an asylum, hospital, or licensed house.

5. I give this certificate having first read the section of the Act of Parliament printed below.

DATED this _____ day of _____
One Thousand _____ Hundred _____

(SIGNED)

of _____

Extract from Section 317 of the Lunacy Act, 1890.

Any person who makes a wilful misstatement of any material fact in a medical or other certificate, or in any statement or report of bodily or mental condition under this Act, shall be guilty of a misdemeanour.

¹ If an urgency certificate is required it must be added here.

(Form No. 9.)

² Strike out this clause in case of a private patient whose removal is not proposed.

³ Insert full postal address.

DR. FINNY'S CERTIFICATE.

Dr. W. E. St. Lawrence Finny, of Clifton Hill, who signed the second certificate, has been good enough to inform us that, acting on the request of Mr. and Mrs. Lancheater, whose family medical attendant he is, he called on October 2nd at the Priory, Roehampton, and had an hour's interview with Miss Edith Lancheater. From the character of the statements made to him by her, and her general demeanour, he felt it to be his duty to sign the certificate in the ordinary form at about 2 p.m. on that day. At 3 p.m. Mr. Lancheater called at the Priory, and took Dr. Blandford's and Dr. Finny's certificates to a magistrate who, however, was not at home. The Commissioners in Lunacy attended at the Priory at 5 p.m., and after an interview with Miss Lancheater, ordered her release, so that it would appear that she was never in fact detained on Dr. Finny's certificate. Under these circumstances it does not seem necessary to make public the further observations of Dr. Finny as to Miss Lancheater's condition at the time of his interview with her.

MISS LANCHESTER AT THE ASYLUM.

From inquiries which we have made we understand that on arrival at the Priory Miss Lancheater immediately demanded to see the medical officer. On seeing him she entered fully, and with considerable volubility, into the position of affairs which had led to her removal. Doubtless this was quite natural, but it tended to give a certain support to the allegations in the certificates. We believe that these certificates pointed out her apparent inability to recognise the moral obliquity of the step which she proposed to take, and detailed certain facts in regard to family history—in which there is undoubted taint of insanity—and other matters which were such that the medical officer felt that, the certificates being quite in order, he had no alternative except to admit her as a patient.

On admission, she was given into the charge of a companion, and, at her own request, was at once provided with some refreshment. In the later part of the day she displayed considerable emotion at her position, but she passed a good night.

In consequence of statements made in the certificates and for other reasons—especially the fear of any rash act on her part—it was thought well that she should not be left without supervision, and for the first two nights a nurse sat up with her. The talkativeness or excitement, however, which had shown itself on her first admission soon passed away, although whenever the subject which had led to her removal was mentioned she showed perfect willingness to discuss it; but she did not, as at first, refer to it unless the topic was introduced. On the third night it was not thought necessary that she should be sat up with, but the nurse slept in the room with her.

As soon as she was admitted proper copies of the certificates were forwarded to the Lunacy Commissioners in time to arrive at the office the same (Friday) afternoon. The father of the patient was at the same time given to understand that if she was to remain at the Priory a second certificate from another medical man would have to be obtained, and that arrangements would have to be made to present those before a justice of the peace in order that an order for admission might be issued.

It should be noted here that although Miss Lancheater had rooms in London, she had by no means severed her connection with her home. She had her own room at her father's house, and generally went down there about once a week.

We believe that the usual medical attendant of the family, although he had not actually attended the patient, had from his knowledge of the circumstances and the family history arrived at the conclusion that her conduct was fully in accord with the idea that she was insane, and after visiting her on Monday he certified to the effect that he considered her of unsound mind.

On Monday, however, she was visited by the Lunacy Commissioners, who after full inquiry came to the conclusion that in the terms of the Act the patient appeared to be "detained without sufficient cause," and ordered her discharge. They did not, however, as has been reported in some papers, immediately set her at liberty, but ordered that she should be discharged on or before November 1st.

Under these circumstances Dr. Chambers, knowing that she certainly would not return to her father's house, and not feeling justified in turning her out without any arrangements having been made for her reception, took her as a guest in his own house pending further arrangements, and communicated with the Lunacy Commissioners.

At the office of the Commissioners the father of the patient met Mr. John Burns, and with him returned to the Priory. Later on Mr. Sullivan appeared, and when Miss Lancaster left she was accompanied by Mr. Burns and Mr. Sullivan, the arrangement being that she should return to her rooms in London in the house of Mrs. Gray.

We believe that after her discharge had been decided upon, the Commissioners urged upon her in the strongest terms the necessity of reconsidering her intentions as to her future arrangements, pointing out the disastrous consequences which might follow upon her proposals, and expressing their sorrow that they were unable to sanction stronger measures, with the object of protecting her from herself, and it seems not improbable that the influence of those with whom she has associated herself may have some effect in emphasising this advice, and bringing about some legal form of marriage in place of the arrangement she had thought of. It is quite clear that the very last thing which practical Socialists would desire would be the popular association of their ideals with a loosening of the marriage tie. It is a sad case, and one which it is difficult to think of without forebodings.

The outside public may, however, derive from it the very comfortable assurance that no one nowadays can be detained in an asylum on a false pretence of lunacy, however wildly people may talk, comparing urgency orders to the *lettres de cachet* of old.

THE PROVISIONS OF THE LUNACY ACT.

We turn to the consideration of the provisions and safeguards with regard to the kind of order ("urgency order") on which the subject of the recent affair was removed from her home.

In cases of urgency where it is expedient, either for the welfare of a person (non pauper) alleged to be a lunatic, or for the public safety, that the alleged lunatic should be forthwith placed under care and treatment, such person may be received and detained in an institution for lunatics upon an urgency order, made, if possible, by the husband or wife or by a relative of the alleged lunatic, together with a statement of particulars, accompanied by one medical certificate. A medical statement as to the reasons for urgency must also be contained in the certificate. The urgency order and statement of particulars, the medical certificate and statement, must all be in the several forms prescribed by the Act. The person signing the urgency order must have personally seen the alleged lunatic within two days before the date of the order; the alleged lunatic must be received within two clear days of the medical examination; the order, then, is in force for seven days from its date, or until a pending petition for a reception order (if there be such) is disposed of. For longer detention, the whole full proceedings are necessary, namely, petition to the "judicial authority," with statement of particulars, two medical certificates on examination, and order for detention signed by a judicial authority. These are the chief provisions; a number of other existing and minor provisions and safeguards would be tedious in recital. The great point is that the urgency order is of very brief force, and the whole machinery for ordinary reception orders must be put into action, and the whole business done fully from the beginning in order to secure detention under a regular reception order should the same be found necessary. Properly used the provisions as to urgency orders are immensely to the welfare of a few lunatics and in favour of the public safety. They are the outcome of a recommendation made by the Parliamentary Select Committee on Lunacy Law in 1875—a Committee before which the burning lunacy questions were thoroughly threshed out, and which reported so fully after hearing patiently all shades of opinion. This Select Committee appointed by Parliament reported that "the difficulty which presents itself at the outset is the universally conceded importance of the speediest possible treatment of the first symptoms of derangement. This might doubtless be carried on, and in

many instances better carried on, outside the walls of an asylum, but in most cases such would be obviously impossible, nor would an intermediate hospital, which has been suggested, effectually prevent the onset of insanity from attaching to temporary cases. Any impediment to the rapid conveyance of a patient to an asylum might, in some instances, render the case hopeless."

The urgency order is a most valuable provision in some cases, as, for example, when a person becomes deranged at home or in lodgings, and is violent, dangerous, destructive, or bent on suicide, and perhaps making violent attempts to that end.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary.*

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

SOUTH-WALES AND MONMOUTHSHIRE BRANCH.—The next meeting of this Branch will be held, by the kindness of Dr. Pringle, at the County Asylum, Bridgend, on Tuesday afternoon, November 19th. Members are requested to give notice of communications to be brought before the meeting before November 8th, to D. ARTHUR DAVIES, M.B., Swansea.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH. The first meeting of the Branch was held on October 10th, Dr. CARTER, President, in the chair. Sixty-two members and visitors were present.

New Members.—The following members of the Association were elected members of the Branch: Elizabeth Beilby, M.D., Northern India; R. W. Henry, M.B., Eye Hospital, Birmingham; O. R. Lewis, M.B., Perry Barr.

Proposed Ethical Committee.—The question of forming an Ethical Committee was discussed. The Branch agreed as to the desirability of appointing such a Committee, and referred the matter to the Council to formulate a scheme.

Gastro-Enterostomy.—Mr. HASLAM showed a man, aged 64, on whom he had performed a gastro-enterostomy to relieve the symptoms of a pyloric obstruction from growth. The abdomen was opened in the middle line above the umbilicus, and the pylorus was found as an indurated mass of tissue closely adherent to the neighbouring structures, so much so that excision was not practicable. The jejunum was attached to the anterior surface of the stomach by an oval Murphy's button, and the abdominal wound closed. The patient did well, and had only vomited three times since the operation. He was able to eat ordinary food, and had no pain whatever; he had gained 10 pounds in weight, and was apparently quite well. The button had not yet passed, nor could any trace of it be made out.

Spontaneous Perforation of Pregnant Uterus.—Mr. CHRISTOPHER MARTIN showed a pregnant uterus, removed by abdominal section, in which spontaneous perforation had

been caused by hydatidiform disease of the chorion. The patient was aged 26, married five months, and three months pregnant. She was perfectly well until forty-eight hours before the operation, when sickness and diarrhoea set in. Next day symptoms of abortion occurred. Eight hours before operation Dr. Wilson, of Boston Beach, removed from the vagina a large mass of "hydatid mole," but no instrument was introduced into the uterus. When seen shortly afterwards by Mr. Martin she was blanched and collapsed, with a cloudy pulse of 130, and obviously suffering from acute internal hemorrhage. The uterus was enlarged and empty, and digital examination discovered no sign of perforation. The abdomen was opened without delay and found full of blood. On the right side of the anterior surface of the body of the uterus was a raised oval purple swelling as large as a walnut, in the centre of which was a pointed perforation the size of a three-penny piece, through which a lot of chocolate residue was protruding. The tissue of the uterine wall around this perforation was undermined and infiltrated with chocolate growth. Mr. Martin at once decided to perform total extirpation of the uterus. The broad ligaments on either side were quickly ligatured and divided down to the vaginal ring. The bladder was separated from the uterus, the vagina opened, and the uterus removed. The abdomen having been washed out, the ligatures on the broad ligaments were drawn down through the vagina, the latter stuffed with iodoform gauze and the abdominal wound closed. The patient though not so bad as her nearly pulseless, rattled well, and in the fifth day was out of danger. Mr. Martin said that spontaneous perforation of the gravid uterus caused by infiltration of the wall with pyogenic cocci and other virus was exceedingly rare. He could find only four cases on record. All of these had died, one from peritonitis and the rest from interperitoneal hemorrhage. The present case was apparently the only one which had been saved by surgical interference.

Dissected Valvula of Lung.—Dr. Farwell showed the middle lobe of the right lung of a man who had died of tuberculous phthisis. When first examined, six weeks before death, the physical signs over this lobe were: movement absent, subparietal percussion note, breath sounds heard apparently distant but vesicular. Though no sputum could be obtained, Dr. Farwell suspected a small pneumonia, whose contraction with the lung had become closed, the breath sounds heard being those of the adjacent fully healthy tissue. Inspected examination during the next fortnight did not alter this opinion, though a few less curiously, but before death the breath sounds had become harsher and louder, one or two cracks could be detected, whilst the percussion note remained as before. The diagnosis now lay between emphysema and disseminated tubercles. The latter was chosen, as the breath sounds were far less grating than those usually heard over a patch of emphysema, and as tubercles a membrane and the cracks were more fine. The section shown confirmed the diagnosis, the tubercles just beneath the anterior surface occupying singly, but some twofolds of an inch from this small nodules appeared, the tubercles forming these being said for the most part coarse though moderately progressed. This striking confirmation of the existence of Roache's classical description of the signs of valvula tubercle is, in Dr. Farwell's experience, sufficiently rare to make it worthy of record.

The Nephritic Subject of Treatment of Heart Disease.—Dr. Farwell read a paper on this subject, which is published at p. 1181. Dr. Edwin Thomas said he was by no means opposed to the view held by Dr. Schott as to the methods following upon pericardial contractions as the treatment, but, at the same time, clinical observation of cases in which there existed some obstacle to the rapid filling of the ventricle, such as obstruction in the course of the pulmonary artery and other disease, in which it had been found necessary to take precautions to prevent in order to avoid the occurrence of overstrain, had led him to believe that an exposure of arterial capacity was induced independently of ventricular contraction, and perhaps in point of time antecedent to it. He believed that such a mode of operation in relieving the heart, and therefore in diminishing the force of pulsation. With regard to the objection that exposure of arterial capacity had been observed to produce the pulse, he thought that it was

quite conceivable that it would do so if the heart were not, at the same time, stimulated to more powerful contraction. With reference to Greaves's disease, he said that experience showed that in that class of cases, improvement came very slowly, and that the exposure of it in moderate or rapid moving relief was sure to be disappointed. As regards emphysema of the wall of the heart, he was aware that certain authorities were opposed to the application of the Schott method, and he admitted that even cases should be dealt with in the most careful and cautious manner. Out of three cases which were present in his mind, two, however, had shown marked improvement, and Dr. Schott himself was disposed to modify the adverse opinion he had formerly expressed. With regard to dietary precautions, his observations had led him to believe that strict limitation of solids was not only useless but actually harmful. He concluded that abstinence from water exerted an inhibitory influence on renal excretion, and increased the storage in the blood stream of the products of imperfect digestion and of depraved metabolism, including acid and capillary constriction, and increasing peripheral resistance. He advocated, however, a limitation of carbon hydrates and the free use of nitrogenous foods, on the ground that the former supplied materials productive of gastro-intestinal fermentation, and that the resulting depraved acid encouraged the retention, if not the formation, of uric acid and of other poisonous ingredients of the blood. On the subject of uric acid, he said that he had been taught by Sir William Jenner years ago to believe that all such affections induced degeneration and embolism of the heart, and he therefore held that one of the great dangers of convalescence might be averted by a judicious resort to the methods under consideration. He had especially observed that resolution and repair were hastened in an extraordinary degree after acute affections of the air passages and of the substance of the lungs. He added that it would be difficult to exaggerate the benefit which might be gained in the stage of heart weakness so characteristic of the post-infectious condition. Stress was laid on the importance of removing patients during treatment, and for a short time afterwards, from habitual surroundings. If these conditions were observed, he said that the results of treatment in England would be scarcely less satisfactory than those attained in Nanten.—Sir William Forster could confirm many of the statements made. Some of the cases of cure might seem remarkable, but they could be explained by the effects of better local nutrition associated with improved general circulation. As regards the action of the body on the pulse he recalled some experiments of his own made many years back in connection with sphygmographic work, in which he found that of the same temperature followed by similar results. The stimulating effect of these lightly-charged baths and the pressure they exerted on the surface of the body would have considerable effect on the venous circulation. He himself thought the more the movements of Schott also acted by helping the venous circulation, and by lowering the tendency to stagnation in the veins gave a flow to the heart, and so brought about the increased arterial tension and improved heart action. A method that aided the filling of the ventricle in cases of chronic heart disease was pointed in improving the strength of the heart itself as well as the general nutrition. Hence the after-effects of this method of treatment. It could not help, however, uttering a warning against its application to the treatment of emphysema.—Dr. Wm. Dawkins (Durham) said that from experience of nearly 700 cases of various cardiac affections treated by him at Exeter by nitrogen baths and exercise, he was distinctly of opinion that, used with care and in properly selected cases, these Schott methods were capable of doing a great amount of good in a class of ailments in which the effects of the ordinary methods of treatment were so often disappointing. At the same time he wished to point, as strongly as possible, against their indiscriminate use in all cardiac cases; this course might be most dangerous to the patient, and certainly would tend to prejudice the good faith of the medical profession against a valuable method of treatment. He had devised for use in hearty hearts of six different strengths, the first two containing sodium chloride and sodium chloride, and the later ones, in addition to these ingredients in in-

creased quantities, sodium bicarbonate and hydrochloric acid to evolve carbonic acid gas. The movements, nineteen in number, were given by carefully trained attendants, who were instructed in three strengths of resistance: (1) gentle, (2) medium, (3) firm. Sometimes only two or three movements out of the nineteen were given at one time, and in cases where the patient's state necessitated it were given in the sitting or lying instead of in the standing position. There was no question that these baths and movements produced a slowing, steadying, and strengthening effect on the cardiac action. The cases he had found most benefited by this treatment were endocardial exudations after acute rheumatism, functional cardiac affections, cardiac neuroses such as pseudo-angina, the influenzal and alcoholic hearts, many mitral affections, cardiac dilatation, the "flabby" heart and the early stage of fatty heart. He considered the treatment much less useful in aortic than in mitral affections, and would not advise its use in aneurysm, arterio-sclerosis, and very carefully only in true angina. Mr. Armstrong added that one benefit of these artificial baths was that he had been able to give this treatment in Buxton in the winter just as well as in the summer.—Dr. SIMON thought it right to approach the Naheim treatment in a spirit of careful scepticism. He did not cavil at the results; he accepted them on the authority of those who brought the cases forward. He asked only if it was necessary to attribute the good effects of the treatment to the particular methods adopted, and if it would not be possible to obtain equally good results by a careful use of massage and ordinary exercise under medical supervision as careful and as continuous as that necessitated by the Schott methods. He thought the greatest good to be derived from the promulgation and practice of Dr. Schott's methods was to remove from the minds of the laity and medical profession alike the too prevalent idea that heart disease meant a life of inactivity and a future of apprehension of the effects of even moderate exercise.—Dr. SAUNDY briefly replied, and pointed out that the treatment occupied a position between massage and ordinary exercise where nothing intervened at present.

SHROPSHIRE AND MID-WALES BRANCH.

THE annual general meeting of this Branch was held on October 15th, Dr. CURRERON, President, in the chair. Thirty-eight members were present.

Election of Officers.—Mr. J. D. Lloyd (of Chick) was appointed President-elect. Mr. Harold H. B. MacLeod was appointed Assistant Honorary Secretary. The other officers of the Branch and the members of the Council were re-elected.

Confirmation of Minutes.—The minutes of the preceding meeting were read and confirmed, and the report and financial statement of the Branch Council was read and adopted.

New Members.—The following were elected: O. E. Baddeley, M.D., Newport; J. Esmonde, Pontesbury; G. Higginson, B.A., M.B., Church Stretton; G. L. Procter, M.B., C.M., Dawley.

Vote of Thanks to the Retiring President.—A hearty vote of thanks was accorded to the retiring President, Mr. J. McC. McCarthy, St. George's.

President's Address.—The President read an address on the need for further legislation for inebriates, in which he urged the amendment of the Act now in force in the following directions—namely: 1. The voluntary admission of a patient in the presence of a clergyman, lawyer, or medical man, instead of his being obliged to go before the justices to sign for his admission. 2. The conferring on the proper authorities the power to commit habitual drunkards to retreats. 3. The giving power to guardians to detain pauper habitual drunkards for proper treatment. 4. The providing at public cost for the treatment of inebriates who cannot pay, or who can pay a little, towards their board and treatment. 5. For securing the return of an escaped patient without being obliged, as now, to obtain a warrant, and the taking of a patient before a magistrate.—A discussion followed, in which Drs. J. T. GWYNN, THURFIELD, and Sir WALTER FOSTER took part.

Communications.—Dr. W. N. THURFIELD read a short paper on the Exit Gates of Infection in Scarlet and Typhoid Fevers. In the former he drew special attention to infection

emanating from the throat and naso-pharynx during the first few days, and continuing in discharges from the throat, ears, nose and suppurating glands, even after all desquamation is at an end. In regard to typhoid he adduced evidence showing that urine in the form of bedroom slops is sometimes the source of infection, and insisting that such slops should be disinfected as thoroughly as the discharges from the bowel, and that all excretions should be looked upon as possible sources of infection. In this connection he alluded to the recent discovery of typhoid bacilli in the urine. Sir WALTER FOSTER, Mr. LLOYD, and Mr. CASSAN spoke on this subject.—Dr. ALFRED EDDOWES read notes on the Pathology of Acne and Syphilis, illustrated by photographs and Microscopical Preparations, and gave many valuable suggestions for their treatment.—Dr. FREDERICK EDGE read a short paper on Vaginal Coliotomy, detailing eight cases in which he had operated successfully.—Mr. T. LAW WEBB demonstrated an Improved Method for Obtaining Portions of Mucous Membrane for Diagnostic Purposes. Using an aspirator, a glass tube, and a pair of scissors, he showed how a portion of tissue could be readily drawn up into the tube and snipped off for examination.—Mr. J. McC. MCCARTHY showed cases of Sutured Tendons.—Mr. T. LAW WEBB showed (for Dr. CHARNLEY) Microscopical Sections of (1) Epithelioma of the Buccal Region in man aged 65; (2) Sarcoma of Posterior Pole of Eye in very early stage, three months' growth.—Mr. CASSAN showed a case of Alopecia Areata improving under treatment.—Dr. GARDNER showed a case of Brachial Neuritis in a striker, due to percussion.—Dr. PACKER showed a case of Ectopia Vesicæ with Epispadias.

Dinner.—The usual dinner was held at the Music Hall in the evening, forty-two members and their friends being present.

OXFORD AND DISTRICT BRANCH.

A GENERAL meeting was held on Friday, October 25th, at the Radcliffe Infirmary, Mr. SYMONDS, President, in the chair. More than fifty members were present.

Confirmation of Minutes.—The minutes were read and confirmed.

New Member.—Dr. Winslow was elected a member.

Medical Aid Associations.—The afternoon was occupied by a discussion on the question of members meeting in consultation medical officers of medical aid associations, and finally it was carried:

That a copy of the resolution of January 28th, 1894, be sent to every member of the Branch, with a request that he will answer "Yes" or "No" to the same.

A small Subcommittee was appointed to carry out the preceding resolution, and to define which clubs should be included.

SOUTH-EASTERN BRANCH: WEST SUSSEX DISTRICT.

A MEETING was held at the Chichester Infirmary on October 16th; Dr. PAXTON, of Chichester, presided.

Registration of Midwives.—Mr. G. B. COLLET, of Worthing, opened a discussion on the registration of midwives. The general sentiment of those present was favourable to registration, and it was thought that the fears which had been expressed that registered midwives would irregularly practise medicine and surgery to the detriment of fully qualified practitioners were groundless.

Ichthyosis.—Dr. PAXTON read the notes of a case of ichthyosis. The patient was an adult female. The body and limbs, except the face, hands, and feet, was covered with a thick, dry, scaly covering, which had transverse and longitudinal cracks upon it, and was likened to a crocodile's skin. The condition was congenital; there was no family history of a similar condition. The case was treated with extract of thyroid gland; three tablets daily were given. In three weeks the chest was clear, and the abdomen and back were clearing; handfuls of scales were shed into the bed. Further treatment with two tablets a day for three weeks did not produce much more improvement, and the patient left the hospital, as she would not endure the irksomeness of remaining in bed. She said her skin was better than she ever remembered it. The disease did not cause any great amount of discomfort.

Causation and Mode of Healing of Empyema.—Mr. BILTON

POLLARD (London) read a paper on the causation and mode of healing of empyema of the pleural cavity, considered in relation to prognosis and treatment. He first drew attention to the varying character of the contents of different empyemata, and stated that those in which the pus contained large masses of lymph, or was thick and creamy, healed best; whilst the cases in which the pus was thin or sanious were the least favourable. The fact that the pus was offensive, apart from its other characters, did not much influence the course of healing. The character of the pus was dependent on the micro-organisms it contained. Pneumococci, staphylococci, and streptococci are found sometimes alone, sometimes mixed in varying proportions. The streptococci are the most virulent, are most numerous in thin pus, and indicate an immediate necessity for free drainage. It was then pointed out that the conditions of rapid and complete healing of the empyema were negative pressure in the pleura, expansibility of the lung, and the contact of the two layers of the pleura sufficiently long for adhesions to form. Where all these conditions can be induced by simple aspiration, a cure may be effected by that means. More frequently, these conditions cannot be established, and then aspiration does not bring about a cure. The method of Bülau (siphon drainage of the pleura) is theoretically perfect, but practically is inconvenient and liable to fail through the apparatus getting out of order. In the cases where aspiration and siphon drainage do not succeed harm will have resulted from the delay in using other modes of treatment. In all cases resection of a piece of rib, free incision of the pleura, and continuous drainage are recommended as the best treatment. The mode of healing of a pleural cavity which had been freely opened for empyema was considered. The theory of Roser, that adhesion of the viscera to the parietal pleura was brought about by granulation commencing at the angles where the two layers of pleura were in contact and thence extending over the whole surface of the lung, was rejected on the grounds that (1) this theory involved adhesion of the collapsed lung to the chest wall, and that those cases in which the collapsed lung was bound down to the pleura were those in which healing took place least readily; (2) that complete healing frequently took place in three weeks or less—a time too short for the filling of the pleura with granulations. The theory of Weisengerber, in which direct adhesion of the parietal to the visceral pleura takes place without granulation, was held to be more probably correct. The contact of the two surfaces which must take place before adhesion can occur is brought about as follows: Coughing raises the pressure of the air inside the lung above that on the outside, and the lung expands somewhat; the entry of blood into the vessels of the alveoli assists in maintaining the increase of bulk; a dressing over the wound in the chest wall soon acts as a fairly perfect valve, making the entrance of air in inspiration difficult; the lung continuing to expand under the influence of repeated coughs comes in contact with the chest walls, and the two layers of pleura are held together by a kind of sucker-like action till adhesions have formed. This sucker-like action was proved to exist by cases of surgical empyema, from a wounded lung caused by a broken rib, occurring without pneumothorax. To obtain free drainage an incision should be made over the eighth or ninth rib, a little below and outside the inferior angle of the scapula; a portion of the rib should be excised; any masses of lymph which do not come away should be removed with a sponge, or if necessary with forceps or scissor, since if left behind they form an uneven surface which would interfere with the sucker-like adhesion of the two layers of the pleura. It was advised that empyemata with foetid discharge should not be irrigated, as the discharge usually becomes quickly sweet after drainage; where it remains foetid, immersion in a boracic acid bath was advocated as being safer and more efficient than irrigation. The prognosis depends upon the extent to which the lung expands immediately after evacuation of the pleura; if it is felt to expand well, the case will heal quickly; if it does not expand well, healing will be delayed or may not take place; in the latter case expansion of the lung may be assisted by making the patient breathe compressed air, or by raising the intrapulmonary pressure by making the patient cough or causing him to play upon wind

instruments. In double empyema the prognosis is worse. Simultaneous drainage of both pleurae was considered the best treatment, and cases in which this had been successfully done were related. The fact that both pleurae could be opened simultaneously and respiration be still carried on was illustrated by a boy who was admitted to hospital having fallen from a window upon area railings; a spike had passed into each pleura and air entered freely, but respiration was sufficient and the patient made a good recovery.

Votes of Thanks.—Votes of thanks were accorded to Dr. Paxton and Mr. Pollard for their papers.

WEST SOMERSET BRANCH.

THE autumnal meeting of this Branch was held at Taunton on October 25th; Mr. W. WALTER WALTER, President, in the Chair. There were fifteen members present.

Confirmation of Minutes.—The minutes of the last meeting were read and confirmed.

President-Elect.—It was announced that H. T. Rutherford, M.D., Taunton, had been elected by the Council President-Elect for the year 1894-97.

New Member.—David Brown, M.D., Taunton, already a member of the Association, was elected a member of the Branch.

Letter from Dr. Winterbotham.—A letter from Dr. Winterbotham, expressing his thanks for the vote of sympathy which was passed at the last meeting, was read.

Club Practice.—Mr. C. E. Ansbert read a paper on club practice and its abuses, which was well discussed by the meeting; and a resolution in the following terms was then passed:

That a committee consisting of the following gentlemen—namely, Dr. Macdonald, Mr. Willcocks, Mr. Husbonds, and Mr. Abbott, of Taunton; Dr. Meredith, Wellington; Mr. Wilberforce Thompson, Bridgewater; and Mr. Marsh, Yeovil, with power to add to their number—be appointed to inquire into the abuse of clubs, and report to the Council what action can be taken thereon. Mr. Abbott to be convener.

Communications.—The SECRETARY read a short paper sent to him by Dr. JAMES STEWART on Inebriety among the Cultured and Educated Classes.—Dr. LYNDON (Wellington) read notes of a case of Compound Comminuted Depressed Fracture of the Skull. The patient, who had made a perfect recovery, was in attendance.

STIRLING, KINROSS, AND CLACKMANNAN BRANCH. THE autumn meeting was held at Stirling, on October 22nd. Dr. McVAIL was in the chair, and there was a good attendance of members.

Confirmation of Minutes.—The minutes of the previous meeting were read and signed.

New Members.—The following new members were elected: Dr. Hosack Fraser (Bridge of Allan), Dr. Chalmers (Stirling), and Dr. Lumsden (Denny).

Financial Report.—Dr. FERGUSON (the Hon. Treasurer) presented his report of the income and expenditure of the Branch, and the report was adopted.

Report of Council.—The report of Council for 1894-95 was received and adopted.

Election of Office-bearers.—The following were elected office-bearers for the ensuing year:—*President:* Dr. Fraser (Kilninchy); *Vice-President:* Dr. Macpherson (Larbert); *Hon. Treasurer:* Dr. FERGUSON, *Hon. Secretary:* Dr. Lewis. *Members of Council:* Drs. Strachan, McVail, Cribbes, and Baird. *Representatives on General Council and Parliamentary Bills Committee:* Dr. Strachan.

Next Meeting.—It was suggested that the next meeting should be held at Alloa, and it was remitted to Council to fix definitely.

Medical Defence.—A resolution from Edinburgh Branch on this subject was read.

Medical Clubs, etc.—A circular from the North of Scotland Branch was read, and after discussion it was resolved to refer the subject to a committee consisting of the Council, with the addition of Messrs. Ronald, Milne, Hight, and Haldane.

Midwives Registration Bill.—The amended form of this Bill was presented.

Presidential Address.—Dr. McVAIL delivered an address en-

titled *Gleanings from Practice*, in which he referred to club practice and its relation to the supply and demand of doctors; to the death of Dr. Thomas Keith and his work; to the treatment of wounds and the experience gained in ten years' surgery in Kilmarnock Infirmary; to the effects of chill and its treatment; to diaphoresis and antipyretics; and to the *vis medicatrix Naturæ*.—Several members took part in the discussion that followed, and Dr. McVail received a very hearty vote of thanks for his interesting address.

HALIFAX, NOVA SCOTIA, BRANCH.

The annual meeting of this Branch was held at Halifax on October 3rd, Dr. Mansom (President), in the chair.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

New Members.—Surgeon-Colonel O'Dwyer, M.S., and Fleet-Surgeon Grant, R.N., were elected members of the Branch.

Report of Council.—The SECRETARY read the annual report of Council, showing the Branch to be in a very flourishing condition. Eleven meetings had been held during the past year; a large number of papers were read and cases shown. Regret was expressed at the removal of Surgeon-Colonel Archer and Surgeon-Captain Barefoot from this station.—The report was on motion adopted.

Treasurer's Report.—The Treasurer's report was received and referred to the Auditing Committee.

Election of Office bearers.—The following were then elected office bearers for the ensuing year:—President: Thomas Trenaman, M.D. Vice-President: M. Ohisholm, M.D., L.R.C.P. Treasurer: M. A. B. Smith, M.D. Secretary: G. Carleton Jones, M.D., M.R.C.S. Council: Surgeon-Colonel O'Dwyer, Drs. Tobin, Farrell, Campbell, Millsom, Almon, and Kirkpatrick.

Representative on the General Council: William Tobin, F.R.C.S.I.

CORK AND SOUTH OF IRELAND BRANCH.

The annual general meeting of this Branch was held at Cork on October 26th, Professor E. R. Townsend, M.D., President, in the chair.

Confirmation of Minutes.—The minutes of past meetings were read and confirmed.

Treasurer's Report.—The Treasurer's report showed a credit balance of £9 19s. 5d.

Election of Office-bearers.—The following were elected officers for 1895-96:—President: Dr. N. J. Hobart. Vice-President: Dr. Curran (Killeagh). Ex-President: Professor E. R. Townsend, M.D. Representative on Council of British Medical Association: Dr. A. W. Sandford. Representative on Parliamentary Bills Committee: Professor E. R. Townsend. Honorary Treasurer and Secretary: Dr. Philip G. Lee (25, Patrick's Hill, Cork). Council: T. B. Moriarty, M.D., Professor S. O'Sullivan, M.D., F.R.C.S.I., A. W. Sandford, M.D., T. Gelston Atkins, M.D., O. T. Woods, M.D., J. Cotter, M.D., F.R.C.S.I., Professor H. Corby, M.D., R. Burke, M.D. (Douglas), P. J. Macnamara, M.D., F.R.C.S.I. (Kilmallock), W. A. Cummins, M.D., P. J. Cremin, M.D., D. B. O'Flynn, M.D. (Glanmire).

Hospital Abuse.—It was decided that the Honorary Secretary send copies of the British Medical Association notices to the secretaries of the committees of the different hospitals, asking them to get sanction of their Board to have these notices hung up in the different waiting rooms and externs. It was further proposed that the subject of hospital abuse and the rest of the agenda paper be reconsidered at an adjourned meeting to be held in one month's time; a week's notice to be given to each member.

Dr. Ryan, a medical man in the South of Ireland, who as a lad of 20 served in the Anglo-American ambulances in 1870 from the battle of Sedan onwards, through the campaign on the Loire, and during the occupation of Orleans by the Bavarians, their expulsion therefrom by the French, and the subsequent capture of the city by the Prussians, is, according to the *Athenæum*, about to bring out a narrative of his experiences. It will be published by Mr. Murray, under the title of *With an Ambulance during the Franco-German War*.

SPECIAL CORRESPONDENCE.

PARIS.

A Threatened Strike among the Dressers of the Paris Hospitals. — The New System of Out-Patient Visiting — Death of a Doctor from Starvation. — A Statue to Pasteur. — Fire at the Trousseau Hospital. — General News.

ON October 22nd, the competitive examination for hospital dresserships and clerkships ought to have been held. Precautions had been taken against disturbance by the students but without very satisfactory results. An *externe* addressed his comrades before the examiners arrived. He told them that the Assistance Publique intended to stop the 30 francs a month hitherto paid to *externes* of hospitals situated at a distance from the central parts of Paris. He urged them to prevent the examination from taking place, and afterwards to hold a meeting at the École Pratique. His speech was loudly applauded and a good deal of disorder ensued. When the examiners arrived they were greeted with applause, but Dr. Lepage, the president, who is the son-in-law of the Director of Public Assistance, was not allowed to speak. His words were drowned by imitations of the cries of animals and indescribable uproar. After a time the examiners left the amphitheatre, and the students betook themselves to the École Pratique, where a meeting was held with thoroughly negative results. For many of the candidates this incident is of great importance, on account of the approaching time of military service; if no examination is held this year it means a year lost for them. On the following day a further meeting was held at the Faculty of Medicine, at which the same disorder prevailed. M. Brouardel, the Dean of the Faculty, nevertheless succeeded in making himself heard. He insisted on having peace and order, and offered to treat with the Assistance Publique on behalf of the *externes*. This offer was enthusiastically accepted. A strike was suggested, but the proposition was immediately rejected in the interests of the patients. A deputation to M. Peyron, the Director of the Assistance Publique, was decided on. The case from the point of view of the Assistance Publique is as follows: The idea was to place all *externes* on the same footing; the allowance made to the *externes* of what are called "eccentric hospitals" was no longer reasonable, inasmuch as the extension of the City of Paris has lessened the distances, and Beaujon, Lariboisière, and Necker Hospitals, etc., are almost as easily accessible as others. By the stoppage of this allowance a saving of £292 a year will be effected. The latest news concerning this rebellion announces coming peace, or at least a truce. At a meeting of the Municipal Council, M. Alpy declared that in the Budget of 1896 the allowance to the *externes* ought not to be omitted. M. Strauss received a deputation of the *externes* at the Hotel de Ville, who promised them that the Municipal Council would immediately consider the question. At a meeting of the students, October 27th, the Director of the Public Assistance sent them a message confirming the favourable intentions of the Municipal Council. The majority of the students immediately voted that the examinations be held as usual if they be open to lay as well as military candidates. This decision will be presented to M. Peyron by a deputation of hospital dressers.

It is not only among the students that rebellion against the Assistance Publique is rife. A number of hospital physicians have protested against the new regulation called "*circoscriptions hospitalières*," and against out-patients being seen by a physician not attached to the hospital, but appointed specially to give these consultations. Professor Dieulafoy, of the Necker Hospital, has publicly announced his attention of giving the consultation to the outpatients. This resulted in a larger number of students (about sixty) attending the consultation. Professor Dieulafoy, who, escorted by this imposing group of students, made his appearance in the consulting room at the same time as Dr. Méry, formerly *interne*, who had been officially appointed by the Assistance Publique to take charge of the out-patient department. The latter, with great good sense and tact, deferentially left the place vacant for his older and more influential

colleague. After the consultation Dr. Dieulafoy and his body guard withdrew. The administration has this time admitted the patients indicated by Dr. Dieulafoy to the hospital; but as to what will occur on another similar occasion the event will show.

The *Journal de Médecine* calls attention to the sad case of Dr. Armand de Lauglard, who after fifty years of honourable practice found no other way of escaping starvation than suicide. The same *Journal* estimates that there are 2,500 medical men battling with starvation, borne down by heavy rent and taxes. Year by year the number of medical men increases, while owing to the progress of hygienic science, and still more to the disastrous competition of the hospital out patient rooms and private gratuitous clinics, the number of patients decreases. It is the doctors themselves, says M. Lutaud, who have created their own misfortunes. They have taught lady patronesses of different societies to diagnose diseases, to dress and bandage wounds, to vaccinate their own children and those of their neighbours. Medical science is vulgarised in every way. Doctors write in important daily papers explaining how bronchitis and cramps of the stomach are to be cured, and in fashion journals they teach how to cure pimples and avert headaches. Furthermore, they have urged that hospital treatment be paid at the rate of 4s. 2d. per day; the middle classes profit by this tariff to become hospital patients, their conscience at ease since they pay. Five hundred thousand gratuitous consultations are given yearly in Paris dispensaries, and in this way a large amount of fees is diverted from the medical profession. M. Lutaud includes in his indictment the Associations des Dames, more or less patriotic, which send forth thousands of women who, because they have attended a few medical lectures and walked the hospitals for a few weeks, believe themselves to be something very like doctors and treat their families and friends. This school of medical half-knowledge has been created and kept going by medical men, who are now being crushed by the work of their own hands.

The Conseil Municipal of Arbois, the birthplace of Pasteur, has decided to erect a statue to his memory, and that henceforth the municipal college shall be called the Pasteur College. The remains of their *savant* remain at Notre Dame until the exact spot for his last resting-place at the Rue Dutot is decided on. The date of the final burial is not yet fixed.

A fire broke out at the Trousseau Hospital, which was happily discovered at the onset. Forty-five children were laid up with scarlet fever in the pavilion threatened by the flames. They were cleared out and lodged in the pavilion of "doubtful cases." This "contact" is to be regretted, though under the circumstances apparently inevitable. The cause of this misfortune is the faulty installation of the calorifiers.

M. Paul Strauss, at a recent meeting of the Paris Municipal Council proposed that poor children should be provided with sterilised milk in the crèches and in dispensaries.

ROME.

The Health of the Pope.—An Outbreak of Diphtheria at Udine.—The Transactions of the Eleventh International Medical Congress.

Disquieting rumours having lately appeared in a portion of the Italian press, as well as in some of the foreign papers, as to the health of the Pope, I have just had an interview with Professor Lapponi, the Holy Father's physician. The professor informed me that the Pope's health at the present time is perfect, and that since I had my interview with him in January last Leo XIII. has had no illness excepting a slight cold in the spring. His Holiness takes his daily walk in the Vatican gardens; he eats, works, and sleeps as usual, and, notwithstanding that the venerable Pontiff is in his 87th year, his mind is as clear and active as it ever has been. As a proof of this Dr. Lapponi cited the Pope's letter to Cardinal Rampolla, published on October 8th. Professor Lapponi has requested me to contradict a statement which appeared a few months ago in an English journal that His Holiness was subject to fainting fits. The professor says that this statement is not founded on fact, as the Pope is not nor ever has been subject to such attacks; nor has Dr. Lapponi at any time made such a statement to any correspondent.

An outbreak of diphtheria has been reported at Udine, amongst the children of families emigrating to America, who are in the habit of crowding the outskirts of the town before embarking. The disease has rapidly spread amongst the children and several deaths have taken place. The authorities are taking every precaution to prevent the disease further spreading, and have made arrangements to avoid this crowding together of families emigrating in the future.

The second, third, and fourth volumes of the *Transactions of the Eleventh International Medical Congress* have been published, and by this time it should be in the hands of all the members. The fifth and concluding volume, it is expected will be published very shortly.

ALLAHABAD.

[FROM AN OCCASIONAL CORRESPONDENT.]

The Doctrine of the Tea Kettle and the Pasteur Filter.

THE use of the Pasteur filter is being greatly extended. Meanwhile, since the rousing crusade commenced last Christmas in Calcutta by Mr. Ernest Hart in favour of the tea kettle and the filter as a great means of preventing enteric disease, great progress has been made. The following interesting comments appear in the *Pioneer Mail* of October 3rd, relating to enteric fever and the boiling of water: It is said that the proposed experimental use of boiled water by a whole battalion of British infantry at Dinapore has been sanctioned. The tea-kettle theory will then be put to a tolerably severe test. It seems, however, that the experiment is not the first extended trial to which the theory has been subjected. The wing of the Derbyshire Regiment at Benares have boiled all their drinking water since April 1st last, and the results have not been encouraging. On the contrary, it is stated that the admissions for enteric fever have been nearly double that of any previous year. On the other hand, it is also stated that at Meerut, owing to the boiling of water supplied to the British troops throughout the hot weather, there has been practically no enteric in cantonments during the summer. Another small preventive has also given good results, namely, a daily dose of quinine, which has caused a falling off of cases of simple fever as compared with previous years.

BRISTOL.

The Sanitary Control of the Meat Trade.—Injudicious Hospital Advertisement.

THE sanitary conditions of the private slaughterhouses are under consideration. The chief obstacle to the compulsory closure of private houses is the fact that the sanitary authorities have not the power—so long as the house is licensed and fulfils their requirements—to act, for they appear to have had in the past a different opinion of what constitutes sanitary requirements from those recommended by the Local Government Board. Bristol is the centre of the meat supply of the West of England, a large number of cattle being imported from abroad, and a still larger number sent in by train or driven in from the surrounding counties. Bristol has, or had till quite recently, only one meat inspector, and his duties included the supervision of fruit and vegetables. At the entrance to the floating harbour is situated a slaughterhouse, the property of the city, for the slaughter of imported cattle. There are also 25 private slaughterhouses, none of which wholly fulfil the requirements of the Local Government Board: 44 are quite unfit, 21 are passable, and 20 are classed as fit by the medical officer of health. In these private houses over 195,000 animals were killed during last year. These private slaughterhouses are mostly ordinary houses in which the back yard or garden has been roofed over and paved with flagstones. As often as not, the house pump, water-closet, yard sink, and steps to the cellar are included, and the meat is in many cases exposed to the effluvia of manure. The climax was reached in one case where the cattle were driven through the sitting room of the house to get to the yard, the owner appearing to think that the periodic shifting of his furniture was an ordinary event of business routine. It is believed that if a public abattoir was built with proper facilities for approach, near the cattle market, and with properly ventilated slaughter rooms and hanging rooms and cooling

chambers, butchers would prefer to send their animals there for slaughter. The resolution framed by the Sanitary Committee stated that in their opinion a public abattoir was advisable, and the city engineer was requested to obtain particulars as to the cost in other towns of erecting such buildings, and the extent to which they are used.

The Committee of the Hospital for Children have in their wisdom hired a stall at the Handicrafts Exhibition, and display there various surgical appliances, with coats containing bandaged dolls. For some time the nurses were obliged to attend, but, owing to the strong objections made by them and their refusal to come from behind a screen at the back of the stall, the obligation has been withdrawn, as have various pamphlets containing the names of the medical officers. Exhibitions of this sort defeat their own ends, as nothing but condemnation of the want of taste is heard on all sides. It is believed that the takings—for of course money boxes are well to the front—will barely pay expenses.

MANCHESTER.

Tuberculosis in Lancashire.—Royal Infirmary.—Owens College Medical School Extension.

A RETURN has just been issued by the Government showing the number of carcasses seized in consequence of the animals having suffered from tuberculosis. In Manchester, during the year ending March, 1894, 337 carcasses were seized; in the present year, ending March last, the number is given at 302. In Liverpool, the corresponding numbers are for the present year 945 as against 1,505 for 1894; while at Birkenhead the increase is alarming from 142 in 1894 to 1,004 in 1895. The local authorities in Manchester state that in addition to the carcasses condemned by the justices, there have been during the present year 78 seizures of carcasses which were tuberculous.

It is stated that the Manchester Infirmary Board have resolved to sanction an expenditure of £1,000 in preparing plans and estimates for an entirely new building. The "site" question will doubtless prove the crux of the problem.

The very satisfactory entry of medical students at Owens this year has proved, we believe, a source of gratification and encouragement to the College authorities. It is, perhaps, difficult for those residing elsewhere to realise what the Council of Owens College has done for the development of the medical department of Owens College. When one takes into account the fact that—without State aid of any kind—new museums, laboratories, class rooms, etc., for the study of subjects ancillary to medicine, namely, zoology, botany (and geology), no less a sum than £90,000 has been "found" by the Council amongst the local friends of the College; that the present addition to the Medical School—already a very large building—has cost £40,000, it will be seen that the enterprise of the Council of Owens College is second to none in the kingdom. When the Infirmary Committee referred to above has arrived at a conclusion regarding the proposed infirmary extension—as doubtless they will soon—there ought to exist in Manchester a combination of facilities for the study of the clinical and also of more purely medical aspects of our profession, which will at least be worthy of the city of Manchester. Apart altogether from the degree-granting power of the Victoria University—which has its seat in Manchester—the enterprise of its three Colleges—Owens, University, and Yorkshire—in equipping laboratories such as are not to be paralleled in the metropolis is a powerful factor in inducing provincial students to study at the nearest provincial college.

BEQUESTS AND DONATIONS.—The late Mr. Henry Nathan has bequeathed to the Metropolitan Free Hospital, Gray's Inn Road, the London Hospital, and the German Hospital, Dalston, £50; and the Jewish Society for the Relief of the Aged and Needy, the Jewish Widows' Home Asylum, the Birmingham General Hospital, the Birmingham Children's Hospital, and the Birmingham Queen's Hospital £100 each. —The late Mr. Bernard V. Hall, merchant and shipowner, of Liverpool, has left by his will the following bequests:—Liverpool Royal Infirmary, £5,000; Royal Southern Hospital, Liverpool, £2,500; Royal Northern Hospital, Liverpool, £2,500; Ladies' Charity and Lying-in Hospital, £1,000.

CORRESPONDENCE.

LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS AND THE TITLE OF PHYSICIAN.

SIR.—In reply to direct inquiry on the above subject, the Registrar of the Royal College of Physicians (Dr. E. Liveing) has been good enough to place at my disposal the following information, which cannot fail to be of interest to the Licentiates of the College.

The question was considered by the College in 1869 and referred to the Standing Council of the College, Sir Roundell Palmer (afterwards Lord Selborne) and Mr. Denman, Q.C., for an opinion, which was given as follows:

Question submitted to Council: Is a Licentiate of the College of Physicians a physician, and may he so entitle himself?

Answer: We are clearly of opinion that the Licentiates of the Royal College of Physicians who have obtained their licences to practise physic subsequently to December 22nd, 1869, are entitled to call themselves Physicians and to hold appointments as such under 21 and 22 Vict., c. 50 and 38, if duly registered as Licentiates of the College according to sections 27 and Schedule D of the same Act.

(Signed) **ROUNDELL PALMER.**
GEORGE DENMAN.

Lincoln's Inn, Feb. 25th, 1870.

At a meeting of the College on April 11th, 1870, it was resolved that copies of this opinion should be sent to the journals, and it is recorded in the *Lancet* and *BRITISH MEDICAL JOURNAL* under date of April 23rd, 1870.

Until it has been overruled in a court of law, the opinion of two such eminent lawyers as Lord Selborne and Mr. Justice Denman will probably be sufficient for those Licentiates who, like myself, contend that we have a right to entitle ourselves Physicians.—I am, etc.,

HENRY N. HOLBERTON, L.R.C.P.Lond., etc.

East Molesey, Oct. 24th.

SIR.—The letter published in the *BRITISH MEDICAL JOURNAL* of October 19th from your correspondent "F.R.C.P." states that when the class of licentiates was established on its present basis the College consulted the standing counsel to the College, Sir Richard Webster, the present Attorney-General, on this very point, who gave it as his opinion that those on whom the College conferred its licence were thereby legally constituted physicians. Your correspondent speaks with confidence on the point. If, however, by the expression "its present basis" he refers to the basis established in 1861 I think he must have fallen into an error as to Sir Richard Webster having then given any opinion on the subject, as the present Attorney-General was not called to the Bar till some years later than 1861. Whoever the Attorney-General was to whom "F.R.C.P." refers, it would be, I think, very satisfactory if he would furnish you, Sir, with a copy of the opinion for publication.

From the general tone of his letter I gather that it is intended as an authoritative answer to the question raised as to the views of the Fellows and Licentiate Members of the College on the point under discussion.

Assuming that your correspondent's memory is correct as to the effect of the Attorney-General's opinion, that opinion coincides with the opinion expressed in your article, and, if he speaks on behalf of the College, seems to emphasise what was stated in that article, that the title of Physician is now and for the future to be regarded according to its primary signification rather than from the more limited restriction of that title which in the medical world prevailed up to 1861, and still prevails up to the present time in the public mind, the public regarding the physician as the "pure consultant." That primary signification (I quote from a leading English dictionary) is defined to be "a person skilled in physic or the art of healing; one whose profession is to prescribe remedies for diseases."—I am, etc.,

October 26th.

L.R.X.

* Our correspondent "F.R.C.P." evidently confounded Sir Richard Webster with Sir Roundell Palmer, but the correction, far from weakening, rather increases the authoritative character of the opinion, since we now have it on the authority of two eminent lawyers, who were afterwards distinguished ornaments of the Bench that a Licentiate of the Royal College of Physicians is entitled to call himself a Physician. It has, indeed, always seemed to be very difficult to imagine by what other title he could call himself in virtue of his licence.

IRISH WORKHOUSES: "BY THEIR FRUITS YE SHALL KNOW THEM."

SIR,—I have read with great interest the reports of your Special Commission on the management of the Irish workhouses, and I sincerely trust the whole range of workhouses in Ireland may be gone through.

During the time that I acted as house-surgeon at one of the ophthalmic hospitals in Dublin we frequently received cases sent up from the country workhouses for operation or other treatment, and of these workhouses it may assuredly be said: "by their fruits ye shall know them." Most frequently the patients, who were very ill clad, presented the appearance of having never been washed, and I have over and over again found not only their heads but their eyebrows and eyelashes covered with pediculi. In one case—a young girl with ulcer of cornea in which the iris had prolapsed—the very lashes and brows had vermin clinging to nearly every hair. Can there be a more fitting commentary on the state of affairs described in your Commissioner's reports?

In many cases the Boards of Guardians are composed of men who have been elected simply for their political exertions on behalf of the dominant party; their ignorance is often only equalled by their carelessness, and, while the Boards of Guardians will exert all their energies to flatter a demagogue or to condemn anyone who takes a different view in politics from theirs, few seem to care for the lot of the unfortunate paupers who are entrusted to their care. No reform will come if matters are simply left to the guardians themselves. There is need of a strong central authority, and perhaps of financial assistance—for many of the districts are very poor—before any really efficient reforms can be carried out. The remedy must come from without, and the action of the BRITISH MEDICAL JOURNAL in appointing this Commission ought to be the herald of brighter times to come.—I am, etc.,

Great Malvern, Oct. 20th.

HENRY W. JACOB, M.D.

THE MANIA FOR "SENSATIONS."

SIR,—Unfortunately the eager desire to manufacture "sensations" is by no means abating, as the following recent experience of my own will show.

On October 11th, I had occasion to operate on a girl of 19 years to remedy the condition of total absence of the vagina with an enlarged uterus distended with retained menses. Dr. Henry, of Lewisham, administered chloroform, and the girl's aunt was present. I shall send you full details of the case, but it will suffice here to say that the patient died on the tenth day after the operation. I gave the usual death certificate, stating as the cause of death "peritonitis, diarrhoea, and septicæmia after operation for complete vaginal atresia with retained menses on October 11th." This was duly presented to the local registrar, who, without making any inquiries, refused his certificate, directed that funeral arrangements should be delayed, and said the case must be reported to the coroner. The relatives were much distressed and surprised. We, of course, recognized that the registrar, with that small amount of knowledge which is undoubtedly a source of danger, had regarded "retained menses" as a sort of synonym for pregnancy. He had evidently at once, without further inquiry, suspected me of a trivial offence known in law as "wilful murder." He reported the case to the coroner, and in consequence a policeman (the coroner's officer) called on the relatives of my deceased patient, and subjected these ladies to close cross-questioning as to the condition of the genital organs of the deceased, and all the details of the delicate operation to which she had been subjected. They assured the officer that they were fully satisfied with my skill and care in the case. After this I received a request from the coroner for full details of the case, which I of course furnished, at the same time telling him a good deal of what is vulgarly called one's "mind" in reference to what had happened.

Of course, the coroner being a doctor the burial certificate was at last granted without an inquest, and this most painful episode terminated. I am carefully considering what steps I shall now take, but I feel sure that all my professional brethren will agree with me that this kind of thing is absolutely intolerable. I may say that the registrar had not the

shadow of a ground for suspicion beyond his ignorant attempt to read between the lines of my certificate. I understand that the registrar afterwards excused his action by referring to recent "disclosures" as to medical men.

This is the serious side of it, but I hope the day has not yet come when it will be necessary to have a policeman present whenever a dangerous operation is performed in a private house.—I am, etc.,

Hilgste, N., Oct. 27th.

HUGH WOODS, M.D.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

SIR,—It may interest Dr. Rentoul to know, in spite of his evidence from the Calendar and his circular letter, that in 1889 the authorities of Dublin University did then require a certificate of thirty attendances, ten of which had to be personally conducted. This statement is based on personal experience.

In this instance Dr. Rentoul's agitation of 1880 cannot have produced the result he takes credit for.—I am, etc.,

Stapleton, Oct. 28th.

THOS. NORTH.

CERTIFICATED MIDWIVES AND BOARDS OF GUARDIANS.

SIR,—I have read Dr. Lovell Drage's letter with much satisfaction. It is as he says most important that the Council of the British Medical Association should take active steps to carry out the intention of Dr. Welsford's resolution. The Branches have spoken clearly enough on the matter, and we are not without friends on the Council, but in electing future members of the Council it behoves us to select men who represent our views.—I am, etc.,

Southampton, Oct. 28th.

J. F. BULLAR.

CLUBS, CHEAP PRACTICE, AND UNDERSSELLING.

SIR,—In the BRITISH MEDICAL JOURNAL of September 28th, under the above heading, there appears a letter signed "C. Penruddocke, M.R.C.S.," of Wylie, Bath.

Under pretext of drawing attention to a subject of general interest, the writer makes an attack upon "a graduate of a northern university," who "some little time ago purchased a practice in a neighbouring village." The reference is a little obscure, but a client of ours who answers the description feels that some of his brother professional men may consider that the accusation of professional misconduct has been made against him. As a fact, his attention was only recently drawn to the letter by a professional man in London who knows him and the district.

So far as our client is concerned, the accusations are entirely false.—We are, etc.,

Walling Street, E.C., Oct. 28th.

FISHER, CARTER, AND MORE.

"A DANGEROUS VOYAGE."

SIR,—In your editorial in the BRITISH MEDICAL JOURNAL of October 28th, entitled "A Dangerous Voyage," a rumour current here is given a publicity and importance which is not justified by the facts.

I was in attendance upon the Liverpool cotton broker who died of typhoid fever, in conjunction with one of our consulting physicians. We both gave as our opinion that, while there was no doubt of the immediate illness called by the offensive smells of the Manchester Ship Canal, the period of incubation was too short to account for typhoid from that source.

The Canal voyage was on September 31st, and the patient was ill on the 28th, I seeing him first on the 30th.—I am, etc.,

October 28th.

M.D.

SEATS FOR CYCLES.

SIR,—In connection with this topic, and with Mr. Noble Smith's letter of October 28th, I wish to say that I have received many letters from cyclists of all ages who have adopted the seat formed of two circular air pads side by side, and so placed with regard to the pedals and handles that the central tubercles are seated upon the centre of the cupped air pads instead of the usual plan, in which the seat or saddle is so far forward over the pedals that no saddle without a peak is a practicable thing. I venture to call attention again

to my letter of a few weeks past, in which I gave the relative position of seat, pedals, and handles, with the Burgess seat on the modern safety cycle, positions which I have arrived at after twenty-five years of cycling experience; but once placed such a seat too far forwards and it becomes impossible to ride on it, all its great advantages being lost.—I am, etc.,

A CYCLIST OF TWENTY-FIVE YEARS' EXPERIENCE.

October 25th.

THE ADMISSION OF WOMEN TO THE EXAMINATIONS OF THE CONJOINT BOARD IN ENGLAND.

SIR,—The cheers with which the announcement of the small majority against accepting the petition of the London School of Medicine at the Royal College of Physicians were received by the defeated party prove that it will be counted, and not unjustly, as a moral victory. Although the arguments used by those speakers who urged the rejection of the petition of the London School of Medicine for Women were directed mainly or entirely against the admission of women to the medical profession at all, yet it is morally certain that the result of the vote would have been different if this had been the issue. However unpalatable it may be to ladies who have entered the medical profession, I think it ought to be said that another consideration had sufficient weight with a certain proportion of Fellows to prevent them from supporting the acceptance of the petition. It was felt that if women were admitted to the examination for the licence they could not be refused admission to that for the Membership, and finally to the Fellowship. There is a traditional belief that the Fellowship should be given, not as a recognition merely, or indeed at all, of success in practice, but of a desire and effort to contribute to the advance of medicine not only as an art but as a science. Now I fear that it must sorrowfully be confessed that the women who have so far entered the medical profession, however successful some of them may have been as practitioners, have shown little, if any, disposition to add to the sum of medical knowledge. Their contributions to current literature, whether in this country or abroad, but perhaps especially in this country, have been insignificant both in quantity and in quality. The reduction of the majority from one of 59 in a house of 86 to one of 9 in a house of 109 probably indicates that another application will have a different fate, and I venture to suggest that if the moral of the recent division is rightly understood the admission of women would be carried, not only by a large majority, but with practical unanimity.—I am, etc.,

October 25th.

SYMPATHISER.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 5s. 6d., which should be forwarded in stamps or post office order with the notice. The last part on Wednesday is the latest by which these announcements can be received.

A MEDICAL OFFICER of field rank, who expects to go to India about the middle of January next, wants to exchange with an officer who will have one year or longer to remain at home. Liberal terms. In reply state date of arrival home. Answers to be sent to G., 23, Herbert Place, Dagenham.

THE NAVY.

THE following appointments have been made at the Admiralty: RICHARD T. P. GIFFITHS, Fleet-Surgeon, to the *Alexandra*, October 25th; CHARLES A. MACAULEY, M.D., Staff-Surgeon, to the *Pembroke*, October 25th; ALFRED PATTERSON, Staff-Surgeon, to the *Endymion*, October 25th; MICHAEL RONAN, B.A., Staff-Surgeon, to the *Warspite*, October 25th; ERNEST D. MINTRA, Surgeon, to the *Pembroke*, October 25th; MONTAGUE L. B. RODD, Surgeon, to the *Grafton*, October 24th, and afterwards to the *Redpole*, undated; FRANK E. ROCK, M.D., Surgeon, to the *Endymion*, October 24th; REGINALD T. A. LEVINGE, Surgeon, to the *Vernon*, October 24th; FREDERICK D. LUMLEY, Surgeon, to the *Pigmy*, October 24th; FREDERICK J. A. DALTON, Surgeon, to the *Floer*, October 24th; JOHN C. DUNSTON and FREDERICK M. MAY, Surgeons, to Hongkong Hospital, November 1st; HENRY N. STEPHENS, Surgeon, to the *Centurion* additional for the *late*, November 1st; WILLIAM B. MACLEOD, Surgeon, to the *Havty*, November 1st; JOHN H. PRAD, M.A., M.B., Surgeon, to the *Alacrity*, additional, November 1st; ARTHUR E. KELLY, B.A., M.D., Surgeon, to the *Prophet*, undated; HENRY HARRIS and WILLIAM SPRY, Surgeons, to the *Grafton*, undated; E. S. MILLER, M.B. and H. H. PRARCK, Surgeons, to the *Wildfire*, October 25th; OSCAR H. ROCK, Surgeon, to the *Finn*, October 25th; THOMAS W. PHILLIP, M.A. M.B., Surgeon, to the *Jacal*, October 24th; EDWARD S. P. KAMES, Surgeon, to the *Blenheim*, October 24th; JOHN MCELWEE, M.D., Surgeon, to the *Centurion*, October 25th;

WALTER J. BEARBLOCK, Surgeon, to Plymouth Hospital, October 25th. HERBERT CANTON, Staff Surgeon to the *Immortalité*, November 19th; JOHN S. LAMBERT, Staff Surgeon, to the *Narcissus*, November 19th; HOGAN W. MACNAMARA, Staff Surgeon, to the *Cordelia*, November 19th; THOMAS T. JEANS, Surgeon, to the *Immortalité*, November 19th; NORMAN S. SMITH, Surgeon, to the *Narcissus*, November 19th.

ARMY MEDICAL STAFF.

SURGEON-COLONEL W. D. WILSON, Principal Medical Officer, Secunderabad and Bangalore Districts, having completed his term of service, is directed to proceed home.

Brigade-Surgeon-Lieutenant-Colonel H. W. A. MACKINNON, D.S.O., retires on retired pay, October 25th. His commissions are as follows: Assistant-Surgeon, October 2nd, 1865; Surgeon, March 1st, 1871; Surgeon-Major, October 2nd, 1877; Brigade-Surgeon-Lieutenant-Colonel, March 10th, 1889; having received the rank of Lieutenant-Colonel, October 2nd, 1885. He served in the Egyptian war of 1882, and was at the battle of Tel-el-Kebir, where he was slightly wounded (medal with clasp and Khedive's bronze star); he was also in the Burma expedition of 1884-5, with the Upper Burma Field Force under Sir George White, part of the time as Principal Medical Officer (mentioned in despatches, nominated D.S.O.), and received the Frontier medal with clasp.

Surgeon-Colonel H. S. MUIR, on arrival in the Madras Command, has been appointed Principal Medical Officer of the Mandalay and Chin Hills District, Burma, vice Surgeon-Colonel A. F. Churchill, transferred to the Secunderabad District.

ARMY MEDICAL RESERVE.

SURGEON-LIEUTENANT-COLONEL SAMUEL SMITH, having resigned his Volunteer appointment, ceases to be an officer of Army Medical Reserve, October 25th.

Surgeon-Lieutenant F. J. L. WARWICK, M.B., 1st Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Lieutenant, October 25th.

INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON-LIEUTENANT-COLONEL H. H. PURVES, Bengal Establishment, civil surgeon, Howrah, has permission to retire from the service from December 6th next. He was appointed Assistant Surgeon, October 2nd, 1865, and became Brigade-Surgeon-Lieutenant-Colonel, October 2nd, 1885. The remaining extra pension of £100 a year will be allotted to him.

Surgeon-Majors J. W. CLARKSON and J. PARKER, M.D., Bombay Establishment, having completed twenty years' full pay service, are promoted to be Surgeon-Lieutenant-Colonels from September 30th.

Surgeon-Captain C. J. SALKIES, M.B., having completed twelve years' full pay service, is promoted to be Surgeon-Major, September 25th.

Deputy Surgeon-General ROBERT SANDER BATESON, late Bengal Establishment, died on October 24th, at the age of 63. He entered the service as Assistant Surgeon, February 26th, 1866, and was appointed Brigade-Surgeon, October 21st, 1882. He retired, with the honorary rank of Deputy-Surgeon-General, September 1st, 1883. He served in the Indian Mutiny campaign in 1857-59, and was at the action near Agra and the engagement at Dowsa against Tantia Toppe. He had received the Indian Mutiny medal.

THE VOLUNTEERS.

THE undermentioned officers have resigned their commissions, October 25th:—Surgeon-Lieutenant T. J. SCHOLTICK, 2nd Volunteer Battalion the Queen's Royal West Surrey Regiment; Surgeon-Lieutenant R. J. HUGHES, 1st Volunteer Battalion the Royal Fusiliers; Surgeon-Captain T. F. MACDONALD, M.B., 1st Dumfriesshire; Surgeon-Lieutenant R. S. O. DEDFIELD, M.B., 2nd Middlesex (Cyrenaica).

Surgeon-Captain R. T. CASSAN, 2nd Volunteer Battalion the Hampshire Regiment, is promoted to be Surgeon-Major, October 30th.

VOLUNTEER MEDICAL STAFF CORPS.

ACTING CHAPLAIN THE REV. W. KERR SMITH, M.A., Leeds Company, has resigned his appointment, October 30th.

BEARER COMPANIES.

SURGEON-CAPTAIN R. REGINALD SLEMAN ("Artists" R.V.) writes: I beg to answer the questions on bearer companies given in the *BRITISH MEDICAL JOURNAL* of October 25th, p. 1076. (1) The names of volunteer brigades which have bearer companies will be found on pages 316 to 321 of the *Army List*. The Surrey brigade, however, which has a bearer company, has been omitted. (2) There is no official information on this point, as it is neither given in the *Army List* or Volunteer Regulations; but the following will be found correct:

Name of Brigade.	Battalion from which the Bearer Company is Enrolled.
Welsh Border	1st Herefordshire R.V.
East London	1st Tower Hamlets R.V.
Portsmouth	1st V.B. Hampshire Regiment.
South Eastern	1st V.B. Royal Sussex Regiment.
Home Counties	1st V.B. Bedfordshire Regiment. 1st Bucks R.V.

In most of the other brigades which possess bearer companies the personnel is drawn from the regimental stretcher bearers, so that the first line of assistance in the field is wanting. (3) I know of no instance

where the bearer company is administered independently of the battalion organization. (4) Where the bearer company is enrolled on the strength of a battalion or battalions not previously up to its establishment the sergeant is held substantive rank.

BRIGADE SURGEON-LIEUTENANT COLONEL PETER GILES, Welsh Border Brigade Bearer Company, sends some additional information. He writes: "The Welsh Border Brigade Bearer Company has been quite independently administered, earned, received, and spent its grant since organized May, 1880. Sergeants of brigade bearer companies are substantive. Formerly they had, in order to qualify for their preferential grant, to be examined by the adjutant in squad and company drill and musketry as for the grant of a combatant, plus anything or standard the brigade surgeon exacted. As a fact, from the commencement I never promoted even to a lance corporal until the man had passed an examination equivalent to the same rank in the A. M. S. C., but with a man. I find that for corporal of the A. M. S. C. is considered enough for a sergeant of a Volunteer bearer company, and no examination by the adjutant in drill and musketry. Practical experience enables me to give this advice to those commanding bearer companies.

1. Promote no one except he has been examined, and let the examinations be competitive and as practical as possible. Give notice at headquarters at least a month previous to the date of the examination.

2. In deciding upon the promotions, consider the personal qualities of the men compelling, and promote no one who has not moral power with the men, and if in doubt give a lance stripe and confirm if satisfactory.

3. Give a written paper on squad and company drill, guard-mounting, orderly duties, first aid, dispensing, hospital routine, diets, and nursing, and a practical examination on company drill, bearer company drill, and first aid.

When it has been decided who shall be promoted, send the names in for consideration of the officer commanding at the orderly-room for publication in the battalion orders.

If the medical officer is deficient or deficient in his drill either the adjutant or a combatant brother officer who is a good drill can always be obtained as an examiner. On no account whatever should the verdict be in the power of any non-commissioned officer.

MEDICO-LEGAL AND MEDICO-ETHICAL.

ANDERSON V. GORRIE AND OTHERS.

SUPREME COURT OF JUDICATURE (COURT OF APPEAL).

Before the LORD CHANCELLOR, the MASTER OF THE ROLLS, LORD JUSTICE LOPES, and LORD JUSTICE KAY.

IN this case the plaintiff, Dr. Anderson, applied to the Court for leave to restore a notice of motion to the list for hearing, the motion being to have a judgment of the Court of Appeal set aside as being null and void, or voidable. The plaintiff appeared in person.

Dr. Anderson said that in the case of Anderson v. Gorrie and Others, which was an action against the judges of the Supreme Court of Trinidad, tried before the late Lord Chief Justice Coleridge, the jury found that the defendant Cook aggressively and with malice overstrained the judicial powers to the prejudice of the plaintiff and the wilful perversion of justice, and gave a verdict for him for \$600. Judgment, however, was entered against him on the ground that an action could not lie against a judge. From that judgment he brought an appeal to that Court, and what purported to be the judgment of the Court was pronounced, upholding the judgment of the Court below. Since then certain facts had come to his knowledge which he was advised (speaking with all respect) discredited Lord Esher from presiding on that occasion, and rendered the supposed judgment invalid, or void, or at any rate voidable. He was obliged to come to that Court, but he found it constituted in such a way that under the circumstances he did not conceive that it could satisfactorily deal with his application, which was that a court should be properly constituted.

The Lord Chancellor said that, assuming Dr. Anderson's complaint was a good one, it was a matter for appeal to the House of Lords.

Dr. Anderson said that, as his appeal had not been finally heard and determined, the Court had it in its power to set the matter right, and finally hear and determine it. His point was that the Master of the Rolls was disqualified from hearing the appeal from the judgment at the trial. An action had been brought by a barrister against the Master of the Rolls for words spoken on the bench, and that action was subsequently dismissed as frivolous and vexatious, on the authority of the decision of the Court of Appeal in Anderson v. Gorrie.

Lord Justice Kay: What you ask for is leave to appeal against the decision of this Court to another Appeal Court of equal jurisdiction. We can give you no such leave.

Dr. Anderson said that that was totally at variance with his real application.

The Master of the Rolls: What is it you want done now?

Dr. Anderson said that he had given notice of motion to set aside the judgment as voidable, or null and void, and in August last the Court had ordered the motion to be struck out of the list. He therefore served a notice of motion to restore the original motion to the list, and he now applied to have the motion heard, and that the Court should be properly constituted for hearing it.

Lord Justice Kay said supposing the Court now ordered that a Court of Appeal should be constituted excluding Lord Esher, that order would be utterly wrong, because they could not hear such an appeal.

Dr. Anderson submitted that it was not an appeal, but an original motion.

Lord Justice Kay: You have told us that this Court has decided against you, but you think the decision is wrong because Lord Esher was a member of the Court.

Dr. Anderson: No; that is not what I say. I say that the case never was decided, and what was pronounced that day was not a decision, because the Court being so constituted could pronounce no decision.

Lord Justice Kay said that while the order stood it was an order that

would have to be obeyed. In order to get it set aside, Dr. Anderson must go to some Court competent to set it aside; this Court was not competent to set it aside.

Dr. Anderson respectfully submitted that the Court had power over any order which was not a complete and good order. If he could show that there was a real interest on the part of Lord Esher that he should sit on the bench and invalidate the judgment, then he thought he could make good his point that no order as to that person was made, no judgment was pronounced; that what now stood in front of him was only in the form of a judgment, but had no substance. In the case of *Thomas v. Gutterham* the judgment of the Lord Chancellor was set aside for interest; and he thought he should be able to show that in the case of Lord Esher there was an exactly comparable interest to the interest Lord Chancellor Gutterham had when his judgment was set aside.

The Master of the Rolls: How can you do that? You are stating things which are not true.

Dr. Anderson: I have never done so. The Master of the Rolls: The interest of Lord Chancellor Gutterham was a money interest. Now you are saying that that is an all figure with my case, because you say that in some way a man brought against me, which the Court held he ought not to bring, that makes me an interested party in all cases which are to come before this Court. You are a person, I believe, who has been a lawyer, and to say such things as that is absolute and ridiculous nonsense.

Dr. Anderson: I am quite content that your lordship should call it nonsense, but I am not content that your lordship should say it is not true. I do not think I should come here after all I have suffered to be told that I make statements that are not true.

Lord Justice Lopes said that if Dr. Anderson's submission was correct that Lord Esher was disqualified, he too was disqualified, because he had had several actions brought against him, which had been dismissed as frivolous and vexatious.

Dr. Anderson said there was a distinction between the two cases. At the moment when Lord Esher took part in his case there was another action pending against his lordship, and the interest made in his (Dr. Anderson's) case became the precedent by which the action against Lord Esher was dismissed. Without the judgment in which his lordship took part, the law of the country, as previously explained, was the other way. The decision in Anderson v. Gorrie in the Divisional Court was that such action was not frivolous and vexatious.

The Master of the Rolls: What action?

Dr. Anderson: The action against a judge on the ground a judge in Anderson v. Gorrie had been decided by the Divisional Court not to be a frivolous and vexatious action; and if I can show that this action against your lordship was on all fours with that—

The Master of the Rolls: It is too outrageous. The action, I think, was brought by a Mr. Yeatman; about it I never knew anything, except handing it over to the Solicitor for the Crown to deal with; but I believe it was an action in respect of something which he said I said to a jury seven or nine years before. It is too outrageous that the time of the Court should be occupied with such absurd pretence.

Lord Justice Lopes said, even assuming that what Dr. Anderson had said was correct, in his opinion he could not come to that Court.

Dr. Anderson submitted that the Court could deal with the case. He thought he should be able to show that the Court had the power and the duty to constitute a court.

Lord Justice Lopes: Such an application has never been made before from the beginning of time.

Dr. Anderson: And the circumstances under which I am making the application never occurred before from the beginning of time. I do not believe, in the history of England, in the whole of the records such a verdict as I obtained in this case was ever found.

Lord Justice Kay: Or that in the history of this Court any man before you had the courage to raise the point.

Dr. Anderson: There are two points, I say, which without the least disrespect—

The Master of the Rolls: You may depend upon it, so far as I am concerned, I do not want your respect.

Dr. Anderson: I will accept that. Perhaps an occasion will occur when you will.

The Master of the Rolls: I cannot imagine it.

Dr. Anderson: If your lordship will say these things to me, I am sorry to have to answer them. I feel it places me in a false position.

Dr. Anderson then cited the cases of *Thomas v. Gutterham*, *Anderson v. Gorrie*, *Abraham v. Borne and Rogers*, *The Trustees of Great Yarmouth* (8 Q.B.D. 525, *Law Reports*) in support of his argument. He contended that the Master of the Rolls was disqualified by interest from hearing the appeal, and that therefore the judgment should be set aside.

In giving judgment, the Lord Chancellor said that in his opinion there was not the smallest ground for the proposition, and he would not help feeling that it was the greatest possible abuse that the time of the Court should be occupied in repetitions of unimportant observations over and over again, and in a time when he hoped would not be wasted hereafter. The first proposition was that the Court was not competent to deal with a question coming before it in the regular course, because one of its members had had an action brought against him, and that inasmuch as another decision of the Court established the proposition that no proceeding judicially entertained, or of a judicial officer, could an action be then another judge was to be disqualified because he might have an interest in establishing the proposition that no judge could be cited. He could hardly give adequate verbal expression to such nonsense; the thing was too absurd to be treated gravely. Secondly, the proposition was that if there were the least pretence for saying that there was ground upon which the Court was incapable of sitting and determining the case, that inasmuch as it was a voidable judgment the inference was that they could hear it again. He should have thought to anyone familiar with legal procedure it would be intelligible that if that were a true proposition, and the judgment was voidable, it would be a matter of appeal. There was not the smallest pretence for the application, and he regarded it as a somewhat mischievous precedent that so much time should have been wasted upon a matter with regard to which he should have thought no intelligent man

would have had the smallest doubt. He was therefore of opinion that the Court ought not to grant the application.

The Master of the Rolls said he should advisedly take part in the present judgment because he thought that the argument which had been used against his taking part in it was absolutely contemptible. At the same time he only took part in it to say that he agreed with every word that the Lord Chancellor had said.

Lord Justice Lopes, in concurring, said the only way in which he could characterise the application was by describing it as a wanton and unjustifiable waste of time.

Lord Justice Kay said he also agreed with what the Lord Chancellor had said. There was no suggestion whatever, capable of being maintained, that Lord Esher had such an interest as preventing his hearing the case; and if there were, the application was a most frivolous and absurd one. The proper course to take would be to go to the House of Lords. That Court had no jurisdiction whatever to rehear a case which, according to *Dimes's* case, was a final judgment until it was set aside—not void, but voidable only. In his opinion it was neither void nor voidable, and on both grounds the gentleman who had been taking up so much of the time of the Court was utterly and entirely in the wrong.

AN UNQUALIFIED PRACTITIONER FINED.

At the Stipendiary Magistrate's Court at Tunstall on October 24th William Benjamin Davies, of The Victoria, New Road, Talk-o'-th'-Hill, was summoned for having been found guilty of the title of surgeon, implying that he was thus recognised by law, contrary to the 46th Section of the Medical Act, on July 26th and September 3rd. Mr. E. A. Paine prosecuted on behalf of the Medical Defence Union of London, and Mr. E. A. Ashmall appeared for the defence. According to the report in the *Birmingham Gazette*, Mr. Paine said that under the Act the *Medical Register* for the current year was evidence as to whether a medical man was qualified or not, and defendant's name did not appear in the *Register*. He had a sign in his window bearing the name "Dr. Davies, Surgeon," and on the dates named had prescribed for a man named James Allen, of Kidsgrove, charging him 1s. 6d. on each occasion for bottles of medicine, and signing his certificate as being him from work as "M.D." Mr. Ashmall, on behalf of the defendant, pleaded guilty, and represented to the Court that the defendant had studied for the medical profession, but on account of an affection of speech had been dissuaded from entering for the final examination. He was in poor circumstances, in delicate health, and had a weakly wife. He asked for leniency. The stipendiary said the offence was a very serious one, and fined the defendant £10 and costs in each case, £22 4s. in all, or two months' imprisonment.

INSURANCE CASES.

W. is the regular medical adviser of a family named D. S. is a leading surgeon in the same town. Mr. D. sustains some minor injuries by a fall from his trap. W. is called to attend him, and is asked to report to an accident insurance office. He reports, describing nature of injuries, and stating his opinion that the patient will be able to resume part of his work in about fourteen days. Mr. D. and the office have some correspondence as to the lump sum to be paid in settlement of the claim, and the office requests S. to visit and examine Mr. D., which he does without any communication whatever with W., either before or after the visit. 1. Was this a proper proceeding on the part of S.? 2. If not, what should W. now do?

"S." The principle laid down in the appended rule is that by which S. should have been guided, to which, in response to our correspondent's second query, we may add that it would be well to solicit his (S.'s) attention: "When, moreover (an oft-recurring incident) an employer or other person becomes anxious and apprehensive in regard to the illness of an employee, or in the case of an impending action for damages and the like, and for his personal satisfaction requests his own family or other doctor to visit the patient and report to him thereon, it is the duty of the deputed practitioner to point out to the employer or other interested party their respective ethical obligations in the matter, and, prior to making such visit, to solicit and obtain the sanction of the medical attendant in the case, otherwise he will commit a grave breach of professional etiquette, and entail upon himself a just rebuke."—Code, ch. II, sect. 5, rule 1A.

OLD PRESCRIPTIONS.

M.D. writes: I am attending a patient who has cancer of the uterus, and who has several times expressed to me a strong disinclination to take morphine. Recently her symptoms have aroused my suspicions, and on inquiry I found from a relative that she was taking some drops supplied to her by a lady who takes an interest in her. On referring to the London chemist who supplies these "drops" I am informed that they contain "hydrochlorate of morphine, with an excess of hydrochloric acid," and that the lady to whom they are sent has been warned to be careful in their use. On expostulating with the lady I am told that the drops are made up from the prescription of "a first-rate London physician," and that she cannot see any harm in supplying them to the patient without my knowledge, at the same time agreeing to accede to my wishes. Further inquiry leads me to believe that the prescription was originally given to the mother of the lady in question, and that she died some years ago. Since then the prescription has been frequently used for other people in a would-be charitable manner. Will you kindly inform me whether the law permits a chemist to continue for years to make up a prescription containing full doses of morphine, well knowing that he is not dispensing it for the person for whom it was originally ordered?

"S." It is the business of a chemist to dispense drugs according to prescriptions presented to him for that purpose, and there is no legal restriction to prevent him from supplying drugs in that way. When the nature of the medicine ordered appears exceptional it is customary

to refer to the prescriber, if that be possible; if that cannot be done, and circumstances appear to justify refusal to supply a medicine, that course may be adopted sometimes. But it is always a delicate matter for a dispensing chemist to exercise his discretion in that way upon his own responsibility. Very often it may be impossible to determine whether a prescription is or is not to be regarded as a medical instruction for the supply of medicine. The circumstances of the case referred to by our correspondent forcibly illustrate the possible evils and difficulties connected with the customary practice, but it is not easy to suggest a remedy for them that would be effectual.

PUBLICATION OF TESTIMONIAL BY PATIENT.

A CORRESPONDENT asks for our advice as to the proper course to adopt under the following circumstances: In conjunction with three other gentlemen he performed an operation on a patient, and subsequently there appeared in a local newspaper (apparently inserted by or on behalf of the patient, and paid for, we are informed, as an advertisement) a testimonial speaking in terms of commendation of the manner in which the operation had been performed, and expressing the "heartfelt thanks" of the patient and her friends to our correspondent. The latter now inquires what action he and the gentlemen in question (who are naturally annoyed at such publicity) can take in the matter by way of reparation. The publication in question is injurious in so far as it might raise a presumption of having been inserted by way of advertisement on behalf of our correspondent, and that he might be called upon by the General Medical Council for an explanation; but while proceedings against the parties or the proprietors of the newspaper would secure the result of vindication in this respect, such proceedings would necessarily involve considerable anxiety and possible expense; and under the circumstances we think our correspondent should rely on his standing and reputation to rebut any suggestion of improper professional conduct, rather than embark in an expensive action.

A letter to the newspaper in question might be written for publication (subject to the approval of the three other gentlemen referred to), but this course is open to the objection of reviving the original testimonial. Our correspondent has probably administered a warning to the newspaper in question.

A PADDY.—Professionally regrettable and ethically wrong as is the line of conduct imputed to B in relation to A, it is, we fear, the natural outcome of a more or less unethical mind, incited thereto by the unfriendly feeling existing between them. Be the unexplained cause what it may, we would express a hope that, however great the provocation has been, or may be, A will avoid retaliation and continue to act in strict accordance with the ethical rules referred to as better as those by which his individual conduct has therefore been guided.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE.

EXAMINERS FOR MEDICAL DEGREES.—The following appointments of examiners have been made in reference to the First and Second Examinations for the M.B. degree:—Physics: Mr. H. F. Newall and Mr. S. Skinner. Chemistry: Mr. F. H. Neville and Mr. S. Kneemann. Biology: Mr. A. C. Soward and Mr. J. J. Lister. Pharmaceutical Chemistry: Mr. A. Ivatt and Mr. B. H. Adie. Human Anatomy: Professor Macalister and Professor Paterson. Physiology: Mr. W. B. Hardy and Professor Halliburton.

ENTRY OF MEDICAL STUDENTS.—The final returns show that 167 freshmen have entered on the course for the M.B. degree.

EXAMINATIONS.—The Registry publishes the following particulars in reference to the forthcoming examinations for medical and surgical degrees in the present term:

Examination.	Names to be sent in.	Fees and Certificates.	Examination Begins.
First M.B.—			
Chemistry, etc. ...	November 23 ...	November 30 ...	December 6 ...
Biology ...	" 23 ...	December 3 ...	" 9 ...
Second M.B.—			
Pharmacy ...	" 23 ...	" 4 ...	" 12 ...
Anatomy, etc. ...	" 23 ...	November 30 ...	" 6 ...
Third M.B.—			
Surgery, etc. ...	" 27 ...	December 4 ...	" 10 ...
Medicine, etc. ...	" 27 ...	" 4 ...	" 10 ...
M.C. ...	" 27 ...	" 7 ...	" 13 ...

DEGREES.—At the Congregation on Thursday, October 24th, the following degrees in medicine and surgery were conferred:—M.D.: M. G. Foster, M.A., M.B., Trinity; R. R. Law, B.A., M.B., B.C., Christ's. M.B. and B.C.: F. W. Garraod, B.A., Clare.

UNIVERSITY OF EDINBURGH.

A SPECIAL graduation ceremonial was held on October 26th; the Vice-Chancellor, Principal Sir William Muir, presiding, when the fifty-eight gentlemen whose names appeared in the *BRITISH MEDICAL JOURNAL* of October 26th were formally admitted to the Degrees of M.B. and C.M. At the same time eight gentlemen were admitted to the Degree of M.A.

GENERAL COUNCIL.—The statutory half-yearly meeting was held on Friday, October 26th. The only business of medical interest was the election of two Assessors to represent the Council of the University Court, the term of office of Drs. Patrick Heron Watson and John Duncan having come to an end. Dr. Duncan had intimated that he did not desire re-election. It was therefore unanimously agreed to elect Drs. Patrick Heron Watson and Joseph Bell as the new Assessors.

UNIVERSITY OF GLASGOW.

PROFESSIONAL EXAMINATIONS.—The professional examinations at Glasgow University for degrees in medicine are just concluded. The candidates for the first examination numbered 6, including 2 women; candidates for the second 25, including, also, 1 woman; and for the third 61, including 4 women. The passes numbered 3, 10, and 34 for the first, second and third respectively, the remainder having either failed or withdrawn. Under the new regulations there were 185 for the first, including 10 women. Of the total, 71 passed in one or more subjects, 56 failed, and 11 withdrew. Of the women, 9 passed. For the second there were 74 entries, of whom 9 were women. The passes were, in anatomy 30 (10 failures), in physiology 32 (12 failures), in materia medica 37 (18 failures); of the women, 1 passed in one or more subjects.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The following gentlemen, having passed the necessary examination for registered practitioners, have been admitted Licentiates of the College: E. Barker-Barber, L.S.A. Lond., and H. E. Watts, L.S.A. Lond.

OBITUARY.

LAUNCELOT W. ANDREWS, M.D. LOND.

UPON the many students of St. Bartholomew's Hospital between 1882-92 the news of Launcelet Andrews's untimely death will fall as a sudden shock and as a grievous personal loss. Some of his friends had had the painful satisfaction of saying goodbye to him in the last two weeks, when it became evident that his life must shortly close, but to most of his old fellow students this announcement will be one of almost appalling suddenness. In the earlier part of the year one of his testicles was removed for what turned out to be carcinoma. He resumed his work with full vigour and enthusiasm, but after a summer holiday in Switzerland returned to town only to be struck down by a recurrence of the growth in the abdomen, which first showed itself by very obstinate vomiting. This disease rapidly progressed, and he died at 7 A.M. on Tuesday, October 20th, being devotedly nursed by his wife, who is thus left a widow with one son.

Launcelet Andrews, born on March 1st, 1864, was the eldest son of the Rev. W. R. Andrews, of Teffont Ewyas, Wiltshire. He was educated at Haileybury College, where he made many friends, and was a prominent member of the School XV. In 1882 he entered at St. Bartholomew's Hospital, and began working for the London M.B. degree, which he passed in 1889, proceeding to the M.D. in 1892. He was a Member of the Royal College of Surgeons, a Licentiate of the Royal College of Physicians (1889), and a D.P.H. of Cambridge (1893).

From the first Andrews was marked out by his single-hearted enthusiasm and energy; whatever he had in hand, whether work or play, was pursued with an earnest delight in its performance, and it would seem with no further end in view. In his first year he was a member of the Rugby football team, which won the cup (1893), and from that time he was a prominent figure in all the various activities of the schools, a fact that is shown by his long association in various official capacities with the Abernethian Society, of which he was at one time president.

After qualifying he was House-Surgeon to Sir W. Savory, House-Physician to Dr. Andrew, and Ophthalmic House-Surgeon to Mr. H. Power, besides being very frequently *locum tenens* in the only other appointment he did not officially hold—the midwifery assistantcy. After such a prolonged term he was naturally extremely loth to leave and to sever his ties with the hospital.

However, he started on general practice at Stamford, but soon returned to London and set up in Cheyne Gardens, Chelsea, where, happily married, he busied himself in practice and in attendance, first as an assistant at the clerical department at his old hospital, and then for a longer time as Clinical Assistant at the Royal South London Ophthalmic Hospital. The latter post, and the office of Surgeon to the Stone Square Dispensary, he held to the last. Active in body, pure in mind, and with wide sympathies, it is not too much to say that, short as it was, he lived to the full an active and blameless life, the characteristics of which were an intense interest in all things human and an unswerving rectitude of conduct.

NORMAN McLEOD CLERK, M.B., C.M., of Rothesay, who died in July last, was a son of the Rev. Dr. Clerk, Minister of the parish of Kilmallie. After a full course in arts in the University of Glasgow, with the view of settling as an agriculturalist he emigrated to Buenos Ayres, where he remained until, with other Englishmen, he was forced to leave in consequence of one of the revolutions so common in that country. On returning to Scotland he entered himself as a student in medicine in the University of Glasgow, and acquitted himself during his whole curriculum in such a manner as to gain first class certificates in almost all departments. After obtaining the degrees of M.B. and C.M. in 1882, he became one of the House-Surgeons in the Western Infirmary under his uncle, whom he assisted besides in his private practice. He then obtained the appointment of Assistant Medical Officer to Smithston Asylum and Poorhouse, Greenock. While there, however, he had an attack of rheumatic fever, which probably laid the foundation of that delicacy in health which attended him more or less afterwards. He afterwards settled in Rothesay as successor to the late Dr. Maddever. He there pursued his profession in a truly professional spirit, and gained the affection and esteem of all who came under his care. Since a bad attack of influenza in 1892 he gradually declined in health and strength. The end at last came suddenly.

MANY medical men who have studied in Vienna within the last ten years will hear with great regret of the death last week, at the early age of 32, of Mrs. Gordon, wife of the Rev. Francis Gordon, of that city. Not only did Mrs. Gordon assist her husband in his duties as Honorary Secretary of the Anglo-Wiener Medical Association, but she entertained, in a most hospitable manner, English and American doctors visiting Vienna. Numbers of young medical men look back with pleasure to the quiet Sunday evening suppers at her house in Landesgerichts Strasse, when for a few hours they were made to forget that they were "strangers" in a strange land.

MR. GEORGE REDFORD, F.R.C.S., died at Cricklewood, N.W., on October 26th, in his 80th year, after a lingering illness. He was the son of the Rev. Dr. Redford. Mr. Redford has been well known for many years in art circles as a cultivated and accomplished critic. He was an excellent judge of pictures, especially the old masters. In early life Mr. Redford practised as a medical man, and was for some years in the Army Medical Service, having volunteered at the time of the Crimean War. In later years he was officially associated with the Art Treasures Exhibition at Manchester, and also as one of the Commissioners of the Leeds Exhibition.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 4,111 births and 4,011 deaths were registered during the week ending Saturday, October 26th. The annual rate of mortality in these towns, which had been 21.0 and 20.1 per 1,000 in the two preceding weeks, rose again to 21.7 last week. Among these large towns the death rate ranged from 17.1 in Croydon, 13.1 in Huddersfield, and 10.5 in Brighton to 31.8 in Wolverhampton, 26.5 in Salford, and 23.5 in Blackburn. In the thirty-two provincial towns the mean death-rate was 21.4 per 1,000, and exceeded 25.0 by 2.9 the rate recorded in London, which was 17.1 per 1,000. The crude death-rate in the thirty-three towns was 21.7 per 1,000; in the London the rate was equal to 21.7, while it averaged 21.7 per 1,000 in the thirty-two provincial towns, and was highest in Swansea, 26.5, and thirty-two provincial towns, and was highest in Swansea, 26.5, and thirty-two provincial towns. Measles caused a death-rate of 1.3 in Collium, 2.7 in Swansea, and 2.4 in Blackburn; whooping-cough of 1.3 in Warrington, and 1.3 in Swansea, 2.2 in London, and 2.2 in Huddersfield; and diphtheria of 1.3 in Swansea, 2.2 in London, and 2.2 in Huddersfield. The mortality from scarlet fever showed no marked excess in any of the large towns. The 10 deaths from diphtheria in the thirty-three towns included 6 in London, 3 in West Ham, 4 in Birmingham, 1 in Cardiff, and 1 in Wolverhampton. One fatal case of small-pox was registered in London, but none in any of the thirty-two large provincial towns. There were 10 small-pox patients under treatment in the Metropolitan Asylum Hospitals and in the Highgate small-pox hospital on Saturday last, October 26th, against 100, 108, and 110 at the end of the three preceding weeks.

14 new cases were admitted during the week, against 17, 9, and 7 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last was 7,200, against 2,802, 2,837, and 2,430 at the end of the three preceding weeks; 209 new cases were admitted during the week, against 260, 302, and 221 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday last, October 30th, 670 births and 465 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 19.3 and 18.7 per 1,000 in the two preceding weeks, rose again to 18.9 last week, but was 0.6 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 15.6 in Edinburgh to 31.1 in Paisley. The symbolic death-rate in these towns averaged 2.5 per 1,000, the highest rates being recorded in Edinburgh and Dundee. The 251 deaths registered in Glasgow included 9 from "fever," 4 from scarlet fever, 3 from diphtheria, 3 from whooping cough, and 6 from diarrhoea. Four fatal cases of diphtheria were recorded in Edinburgh.

THE DIAGNOSIS OF DIPHTHERIA.

ON the recommendation of the Medical Officer of Health (Dr. Cameron) the Committee of the Leeds Town Council have entered into an arrangement with the Professor of Pathology of the Yorkshire College to investigate on their behalf such doubtful cases as may be reported to him from time to time by the practitioners in charge. It is intended to place at the disposal of any medical man a small "culture outfit," by which he will be enabled to inoculate from the secretions of the throat a small quantity of jelly contained in the sterilised test tube. This will be sent to the Medical Department of the Yorkshire College, cultivated under favourable conditions, examined microscopically, and the result will be reported to the practitioner. The general measures taken for the prevention of infectious diseases, including diarrhoea, have been pushed forward with energy, and year by year, as the city extends and the population grows, the work is necessitating an enlargement of the staff to the department of public health. During the whole of the municipal year the notification of infectious disease has been in operation with a minimum of friction and very considerable advantage to the community in checking the spread of disease.

TYPHOID FEVER AT WEST BROMWICH.

LOCAL reports as to the prevalence of typhoid fever in West Bromwich show that since April, 1894, the Board of Guardians have been called upon to deal with 35 cases of the disease in 25 families, with the result of 28 persons rendered chargeable to the union. The significance of these figures is the more apparent when it is further stated that in the case of 25 of the families the members became pauperised only on the occurrence of the disease. In other words, it would seem that in 30 of the 35 attacks it was only the breaking out of disease that led to the necessity for Poor-law relief applications. This being so, one is led to ask why the Board of Guardians have had to take charge of the cases, and not the local health body—namely, the town council. The reply appears to be that the cases would never have been received into the workhouse if the town council had had any isolation accommodation for the fever patients. The facts would then seem to point to the pauperisation of persons by reason of the neglect of a very apparent duty on the part of the health body in not providing beds for the treatment of fever attacks. And complaint is made that this neglect has added the union generally in the shape of rates for West Bromwich cases. The prevalence has been a fatal one, 3 heads of families having died, and 10 deaths in all having occurred. Nor is this a solitary experience of fever in the borough, as it is the third outbreak in the same locality of the borough within the last two years, and the health officer has strongly admonished on the "foul and open middens" so largely prevailing, giving it as his opinion that so long as the system is allowed to continue, so long will fever continue to recur. The circumstances seem such as to warrant much that has been said in the local press against the inactivity of the health body, and it is time that they bestirred themselves in the direction of additional hospital accommodation, and more especially in the adoption of such sanitary measures as will help to keep the needed isolation buildings empty of cases of a disease of a preventable nature. The iniquity of an open midden system is one that should not be tolerated in a town of the character of West Bromwich; and, if the present trouble only ends in the substitution of a water-carriage system of excrement removal for the prevailing middens, it will have at least accomplished something towards the extinction of typhoid in the place.

YARMOUTH BOARD OF GUARDIANS.

WE are very pleased to note that at a recent meeting of this Board a resolution moved by the chairman, "That the salary of Dr. Collier as district medical officer be increased by £20," was, after considerable opposition carried by 11 to 7. The salary has been hitherto £60 per annum. The increase decided upon by the board appears to us to be a very moderate one, when the amount of work done and responsibility incurred is taken into consideration.

BASINGSTOKE UNION INFIRMARY.

WE are compelled to refer to this subject again, though hardly with the hope of inducing better success in the future. The Inspector, Mr. Bullock, has laid the waste case for and against the new infirmary before the guardians in a most exhaustive speech, wherein he touched upon all points that related to the decision. We trust that the final word has not been spoken, and if that final word comes from the Local Government Board we are convinced that the sense of the country will be in favour of the department putting considerable pressure on the guardians to compel them to follow the only reasonable plan, one that is at the same time humane and economical, that is, to build a new infirmary. We cannot understand a Board who listened to the eloquent pleading of the inspector passing a resolution to patch up the old wards,

by using a chapel as a ward, placing the females in the present infectious hospital, and by thus scattering the patients over the building to increase the difficulty and mar the efficiency of the nurses' work. The report which we published of our Commissioner's visit to this house (September 21st) must convince our readers of the futility of the patch which the Board is trying to put on.

THE BLACKFRIARS SALVATION ARMY SHELTER.

THE hearing of the summons in this case was again resumed on October 24th at the Southwark Police-court before Mr. Stode. Further evidence was called for the defence, and the case was adjourned until November 14th.

A correspondent directs our attention to a note on the subject of this shelter in the *BRITISH MEDICAL JOURNAL* of October 19th, in which he says we were "somewhat inclined to doubt the accuracy" of a particular analysis. We of course intended simply to record the opinions expressed by a witness under examination. Any comment upon the questions at issue must for the present be reserved.

CISTERNS AND THE CONSTANT SERVICE.

DR. W. H. SYMONS, D.P.H., F.I.C. (MANCHESTER HILL, N.W.), writes: In an editorial paragraph in the *BRITISH MEDICAL JOURNAL* of October 10th you draw attention to a form of cistern which Dr. Talbot has provisionally patented. The mere fact of having an inverted cone-shaped cistern of from 1 to 100 gallons capacity would not preclude the accumulation of deposits of micro-organisms, nor would it insure a complete daily change of water, even if the draw-off tap were at the apex.

For many years, when I have been consulted as to the best means of obtaining a small pure supply of water for drinking purposes, I have recommended what I adopted myself in the absence of constant service, tapping the lowest portion of the pipe which leads up to the high service cistern. This pipe is usually 1 inch in diameter, and generally more than 30 feet in length, and therefore will contain over 1 gallon, and supply average wants for cold drinking water. The pipe serves as a cistern which is thoroughly flushed out by the hundreds of gallons of water which daily pass through it. The cost of the alteration need not be more than 5s.; but it is necessary to ascertain that the water has no appreciable action upon the large surface of metal pipe, and that foul air is not sucked in through the terminal tap to replace the water drawn off.

If a sufficient supply cannot be stored in this way, the capacity of the pipe may be increased by inserting in its course a larger earthenware pipe, terminating in a cone at either end where it joins the metal pipe; or, what is still better, a small glass-covered earthenware or glass cistern may be so placed as to intercept the water supply. The ball-cock should be in the main cistern, but the water from the tap, led first to the bottom of the small cistern and then by an overflow into the large cistern, in this way the small cistern is automatically flushed every day by a very large volume of water; of course a second pipe to the draw off tap is necessary. The cistern for drinking water should be so placed that it may be easily inspected, that it is in pure air, and if possible exposed to sunlight.

I have no further acquaintance with Dr. Talbot's proposal than is obtained from reading the *BRITISH MEDICAL JOURNAL*, but I very much question whether any patent would prevent the free adoption of either of the plans I suggest. I advocated this system in the *Standard* of November 10th, 1892, and have no doubt the same ideas have occurred to many others.

As long as interruptions are possible we must provide against the consequent deprivation of water by some reserve, but such that it shall be renewed daily. There is danger of contamination in the entrance of dust and vermin, and the accumulation of deposits in cisterns as commonly fixed in the most improper positions, covered, if at all, with loose boards cut away to admit the supply pipe, and with flat or uneven bottoms. A cistern such as that recommended in an article in the *Sanitary Record* of October 18th, in the form of a cylinder 5 feet in depth, ending below in an inverted cone 1 foot deep, would, if 2 feet in diameter, hold 100 gallons, or if 3 feet, 230 gallons, the cover fitting as close as the lid of a saucepan, and the supply pipe soldered into the side like the overflow, would preclude the entrance of dust, etc., and its conical bottom and outlet render deposits impossible. Even if the water were turned on for one hour only, the cistern would receive enough for the day's wants. There is, however, nothing to prevent the drinking water being drawn directly from the main, colder, though scarcely purer.

INDIA AND THE COLONIES.

INDIA.

CHOLERA IN BURMAH.—The Brahamputra and Irrawaddy valleys have (says the *Bombay Gazette*) sometimes been described as the true home of cholera, and if true home means permanent residence, the opinion is not without warrant. The annual Sanitary Administration Report for Burmah throws some light upon the subject. In 1891, in no month of the year was cholera absent from the province, and it caused the death of over 7,400 persons. The highest mortality always corresponds with the fall establishment of the rains, the minimum with the cold, dry weather. Thus, in July 1,450 people died; in January only 261. Looking back over the past decade we see how the death-rate from the disease varies. In 1883 it reached the high figure of about 16,000; in 1890 it declined to little more than 1,000; in 1892 it rose to over 8,000. In the ten years nearly 85,000 people have died, or an annual average of 8,500. As to the propagation of the disease the most local medical authorities can tell us is what we knew before—that it seems to spread along the lines of human communication.

MEDICAL NEWS.

DR. PHINIAS ABRAHAM has resigned the post of Physician at the Western Skin Hospital, Great Portland Street.

DURING the past week fourteen cases of rabies, all occurring in the west end of the county, have been reported to the Middlesex County Council.

THE first meeting for the session of the Epidemiological Society will be held on Friday, November 15th, at 8 P.M., in the rooms of the Medical Society of London, when Mr. T. W. Thompson will read a paper entitled "Considerations in respect of 'Return' Cases of Scarletina."

THE first lecture of the Royal British Nurses' Association for the present session will be given at 17, Old Cavendish Street, on Friday, November 22nd, by Dr. Louis Parkes, M.O.H. Chelsea, "On the Importance of Breathing Fresh Air."

PRESENTATION.—Mr. Alfred Power, medical officer of the Caylloma Silver Mining Co., Peru, was, on the termination of his period of office, presented by the staff of the mines with a handsome present, and an address expressing their sense of his kindly and skilful discharge of his medical duties.

CHARING CROSS HOSPITAL OLD STUDENTS DINNER.—The annual dinner of past and present students of the Charing Cross Medical School was held on Wednesday, October 23rd, at the Holborn Restaurant, Mr. C. J. Worlett, F.R.C.S., being in the chair. After the toast of "The Queen," the Chairman gave that of "The Medical Staff," which was responded to by Dr. Watt Black. Mr. Waterhouse proposed "The Past and Present Students," responded to by Dr. W. Travers and Mr. Lloyd. Dr. Routh proposed "The Visitors," for whom Mr. Shield replied; and Mr. Morgan gave the toast of "The Chairman." About 155 gentlemen were present, and the meeting was generally felt to have been as successful as any of its predecessors, the success being accentuated by the songs contributed by Dr. Mott and Messrs. A. E. Reade, Hudson, and Leake.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—On Monday, October 28th, in the theatre of the School, Dr. Howship Dickinson distributed the certificates of honour given to students who had gained scholarships, exhibitions, and prizes during the year. The recipients were: Mr. Walwyn Thomas, £100 Exhibitioner and Treasurer's Prizeman; Mr. Sidney Smith and Mr. Frank Morley, Brackenbury Prizemen in Medicine and Surgery respectively; Mr. E. T. Fison, Special Certificate of Honour in Medicine; Mr. R. A. Cooper, Brodie Prizeman; Mr. H. S. Barwell, Henry Charles Johnson and Proficiency Prizeman; Mr. R. E. Drake-Brockman, Brodie Prizeman; Mr. C. R. Keyser, Sir Charles Clarke's Prizeman; Mr. T. M. Neathy, Proficiency Prizeman; Messrs. H. S. Pendlebury, H. G. Deller, and Howell Evans, Entrance Scholars in Science; Messrs. T. C. English, H. A. Chaplin, L. F. Cope, and Lawrence Jones, Entrance Scholars in Arts. Addressing the students at the close of the ceremony, Dr. Dickinson warned them against the danger of becoming one-sided—a danger to be avoided by a legitimate degree of indulgence of an Englishman's natural taste for sport and by the cultivation of the great masters of English literature. For the works of Milton, Addison, and Gibbon the speaker claimed special attention.

MEDICAL VACANCIES.

The following vacancies are announced:

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer and Resident Surgical Officer, Salaries, £200 and £100 respectively, with board, washing, and attendance at the institution. Applications to the Secretary, Children's Hospital, Free-house Lane, Birmingham, by November 15th.

BRISTOL HOSPITAL FOR SICK WOMEN AND CHILDREN.—House-Surgeon; doubly qualified. Salary, £200 per annum, with rooms and attendance (not board). Applications and testimonials, endorsed "House-Surgeon," to H. Lawford Jones, Secretary, before November 6th.

BROWN ANIMAL SANATORY INSTITUTION.—Professor Superintendent, salary, £200 per annum. Applications to the Registrar of the University of London, Burlington Gardens, W., by November 15th.

CITY OF DUBLIN HOSPITAL.—Visiting Surgeon. Applications to Mr. Arthur Benson, F.R.C.S.I., Hon. Sec., Medical Board, City of Dublin Hospital, Upper Baginbun Street, Dublin, before November 15th.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon must be duly qualified to practice medicine and surgery, and be conversant with the Welsh language. Salary, £200 per annum, with board, residence, and washing. Applications and testimonials to W. Vaughan Jones, Secretary, by December 3rd.

GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 124, Buchanan Street, Glasgow, by November 15th.

ROYAL BERKS HOSPITAL.—Consulting Physician must be registered Licentiate in Dental Surgery. Applications to the Secretary ten days before the election on November 15th.

ROYAL PORTSMOUTH HOSPITAL.—Assistant House-Surgeon, appointment for six months. Honorarium of £15 15s., and board and residence, and is renewable for a further period of six months. Applications and testimonials to J. A. Byrley, Secretary, before November 15th.

STOKTON AND THORNABY HOSPITAL, Stockton-on-Tees.—House-Surgeon (non-resident), doubly qualified. Must reside near the hospital, and devote the whole of his time to the institution. Salary, £200 per annum. Applications and testimonials to H. G. Henderson, Secretary, by November 15th.

SUNDERLAND INFIRMARY.—House Physician. Salary, £200, rising £100 annually to £300, with board and residence. Applications to the Chairman of the Medical Board by November 15th.

TOWNSHIP OF TOTTEHAM PARK.—Junior Assistant Resident Medical Officer for the Workhouse Infirmary. Candidates must be registered and doubly qualified. Salary, £85 per annum, with board, washing, and apartments. No extra fee. Applications, endorsed "Junior Assistant Medical Officer," to James Moulding, Clerk to the Guardians, 15, High Park Street, Liverpool, by November 15th.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon; doubly qualified. Salary, £120 per annum, and £20 per annum for dispensing, with furnished apartments and attendance. Applications and testimonials to Tyson Kitchen, Secretary, by November 15th.

MEDICAL APPOINTMENTS.

BATEMAN, C. E. G., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer for the Workhouse and Walsingham District of the Walsingham Union, vice F. Bayes, M.R.C.S., resigned.

BOULTON, A., M.R.C.S. Eng., appointed Medical Officer of Health to the Horncastle Rural Sanitary District, vice H. George, M.D. and A.M.

CARMICHAEL, W. J., M.B., C.M. Aberd., appointed Surgeon and Agent to the Coalguard at Collieston, and Medical Officer for the parish of Slaith, vice Dr. Jameson, resigned.

EDWARDS, Norman Fox, M.B., Ch.B. Viet., appointed House Physician to the Swansea Hospital.

EVANS, Arthur Henry, appointed Resident Obstetric Assistant to the Westminster Hospital.

FLEMING, Dr. G. E., appointed Medical Officer for the Downham District of the Ely Union, vice H. Hulbert, B.A. Oxon., L.R.C.P. Lond., M.R.C.S., resigned.

GARTANG, Thos. W. H., M.R.C.S., Medical Officer of Health to the Kentford Urban District Council, appointed Medical Officer of Health to the Bucklow Rural District Council, late Antworth Rural Sanitary Authority.

GIBBS, F. R., M.R.C.S., L.R.C.P. Lond., appointed Medical Officer for the Eighth District of the Wycombe Union, vice W. G. Weaver, L.R.C.P. Lond., resigned.

GORDON, W., M.A., M.D., R.C. Cantab., M.R.C.P., appointed Physician to the West of England Eye Infirmary, Exeter.

HARDIE, John, M.B., F.R.C.S. E., appointed Examiner in Anatomy at the Royal College of Surgeons, Edinburgh, vice Macdonald Brown, F.R.C.S. Eng., retired.

JOLLY, R. W., M.R.C.S. Eng., appointed Medical Officer of Health for Peterborough, vice W. E. Pagley, M.B. Durh., F.R.C.S. Eng.

MORLEY, H. W., M.R.C.S., L.R.C.P., formerly Assistant House Surgeon, appointed House-Surgeon to the Royal Portsmouth Hospital, vice T. H. Bishop, M.B., resigned.

PATKINSON, H. A., M.R.C.S. Eng., L.R.C.P.I., reappointed Medical Officer of Health to the Seaton Urban Sanitary District.

POLLARD, C., M.D., F.R.C.S., appointed Medical Officer for the Hail District of the Martley Union, vice W. A. S. Walsh, M.R.C.S. Eng.

RANDELL, R. M. Henry, M.D. Lond., M.R.C.S. Eng., appointed Honorary Medical Officer to the Beckenham College Hospital.

STEVENS, F. J., B.A. Oxon., M.R.C.S., D.P.H., appointed Medical Officer of Health to the Camberwell Sanitary District.

TIMMETS, T. M., M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer of Health for the Quarry Bank Urban Sanitary District, vice Dr. W. H. Thompson, deceased.

WEST, Waldemar S., M.A., M.B., R.C. Cantab., appointed Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City Road, E.C.

DIARY FOR NEXT WEEK.

MONDAY.

LONDON POST-GRADUATE COURSE, Latham Throat Hospital, Great Portland Street, 8 P.M. Dr. W. H. Latham, President of the Faculty and Lecturer.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, at Leicester Square, W.C., 8 P.M.—(Inaugural Address by the President, Mr. David Hepburn.)—General communications by Mr. C. J. Boyd Wallace and Mr. J. Mann Stodd.

TUESDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 1 P.M.—Dr. Craig: Alcoholic Insanity.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M.

PATHOLOGICAL SOCIETY OF LONDON, 20, Hanover Square, W., 5.30 P.M.—Dr. Snow: The Non-existence of Round called Sarcoma as a Distinct Class of New Growth. Drs. Garrod and Hopkins: On the Occurrence of Large Amounts of Hematopoietin in the Urine after the Administration of Sulphonol. Mr. Needles: The Relation of Biliary Calculi to Malignant Disease of the Liver. Mr. Jackson Clarke: Dermoid Tumour of the Testis. Mr. Edmunds: Cystic Accessory Thyroid. Card Specimens.—Mr. Needles: Ureter Obstructed by Calculus. Dr. Willocks: Peritonitis and Thrombosis. Dr. Walsham: Pulmonary Metastasis. Mr. Edmunds: Myxoma of Breast.

WEDNESDAY.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Mr. R. J. Godlee: On the Surgical Anatomy of the Chest.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Papers:—Professor G. E. Curalulo (Introduced by Dr. Griffith): On the Influence of the Removal of the Ovaries on Metabolism in connection with Osteomalacia. Mr. J. Head Sutton: On a Case of Tubo-Uterine Pregnancy: Primary Inter-peritoneal Rupture; Recovery. Dr. A. E. Giles: A Case of Uterus Dendelophya, with remarks on the Clinical Importance of this Malformation. Special General Meeting for discussion of revision of Chapter VI of the 1900 Act.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 5 P.M.—Lecture by Dr. Beevor.

THURSDAY.

LONDON POST-GRADUATE COURSE, Hospital for the Paralyzed and Epileptic, Queen Square, 5 P.M.—Dr. Hastings: Cases in the Hospital for Sick Children, Great Ormond Street, W.C. 1. A Lecture on the Hospital for Sick Children, Great Ormond Street, W.C. 1.

HARTMAN SOCIETY OF LONDON, 8.20 P.M.—Dr. Goodhart will open a discussion on Spasmodic Asthma and its Treatment.

NEPHROLOGICAL SOCIETY OF LONDON, Mr. Jonathan Hutchinson's Museum, 1, Park Crescent, 8.20 P.M.—A Clinical Demonstration (Drawings and Photographs) of the Trophoblasts of the Skin, more especially of Papules and Morphæa.

FRIDAY.

LONDON POST-GRADUATE COURSE, Pathological Laboratory, King's College, 3 to 5 P.M.—Professor Crookshank: Lectures on Actinomycosis and Glanders. Practical Work: Staining Sections and Cultivations.

CLINICAL SOCIETY OF LONDON, 20, Hanover Square, W., 5.30 P.M.—Mr. Mansell Moullin: Suprapubic Cystotomy and Prostatectomy in Cases of Multiple Calculi. Mr. Golding-Bird: A Case of Intussusception through a Patent Nicker's Diverticulum. Mr. Langton: A Case of Osteosarcoma (Fragilis Ossium), in which after firm union of several fractures had taken place, disunion occurred in some, several years afterwards. Dr. Althaus: A Case of Brain Tumour successfully treated by Internal Medication.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Percy Smith: Insanity and Syphilis; Insanity with Organic Brain Disease.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

EDWARDS.—On October 27th, at 45, Harley Street, W., the wife of F. Swinford Edwards, F.R.C.S., of a daughter.

MOLSON.—On October 26th, at Springfield, Chelmsford, the wife of J. Molson, M.B., B.C. (Camb.), F.R.C.S., L.R.C.P., of a son.

MARRIAGES.

TUTTIN.—WATKIN-DAVIES.—On October 21st, at St. Michael's, Aberegele, by the Rev. P. P. Watkin-Davies, Rector of Llanvethoron, Denbigh, brother of the bride, assisted by the Rev. Canon Emson, Rector of the parish, Alfred Tuttin, M.B., of Upper Portland, Dorset, youngest son of the late Captain William Tuttin, King's Dragoon Guards, of Mayfield, Maynooth, to Catherine Grace, youngest daughter of the late Rev. David Watkin-Davies, Rector of Llanvethoron, Denbigh.

LEWIS.—LEWIS.—On October 23rd, at St. Catherine's Church, Pontypool, by the Rev. Frederick Lewis, R.D., Vicar of Ystradgynlais, assisted by the Rev. R. J. Williams, B.A., Vicar of Denas Powis, and the Rev. J. P. Griffith, M.A., Vicar of Pontypool, James Lewis Lytle, M.B., M.Ch., M.A.O., of Ystradgynlais, Pontypool, to Edith Mary, eldest and only surviving daughter of the late Rev. Moses Lewis, Vicar of Llanvethoron.

DEATH.

GORDON.—On October 2nd, at 15, Finsbury Avenue, London, N.W., Ethel Be Prior, wife of the Rev. Francis Gordon, of Vienna, aged 32.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MONDAY EVENING. THEIR REPLY CAN BE RECEIVED ON TUESDAY MORNING.

QUESTIONS respecting Editorial matters should be addressed to the Editor, 439, Strand, W.C.; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 439, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 439, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

E. H. F. writes: Is there any post-graduate course where one can have practical instruction in putting up fractures, reducing dislocation, etc.?

X. Y. Z. asks where he can purchase good second-hand surgical instruments.

A MEMBER asks to be advised as to the best plan of treatment in the case of a tall girl, about 13 years of age, becoming "round in the shoulders," and somewhat stooped.

MR. CHARLES ROBERTS (The Lodge, Eastbourne) would be glad to know where he can purchase a large outline diagram of the brain and nervous system—apart from all other structures—suitable for a school-room lecture on physical education.

J. F. F., who has a patient, aged 20, male, with very small chest which he is anxious to see developed, asks to be recommended a trustworthy and competent Swedish drill instructor and masseur, who would attend at a private house.

Q. asks for information as to the following points in connection with starting a parish or district nurse—trained, of course. What remuneration should she require? Is it advisable to make any charge on those who benefit by her services? Where should one apply to obtain a likely person for this position?

C. P. writes: A girl, who in youth suffered from caries of the spine, has slight dilatation of the stomach, and is troubled with a gurgling, churning noise at every inspiration and expiration. I have distended her, keeping down the liquids, and also used oil of rue, but with no marked effect. Can any readers recommend anything to remove the unpleasant noise in her stomach?

E. H. asks for advice in the treatment of a patient who has on the buccal mucous membrane about 100 small white ulcers about 2 lines in diameter. E. H. has given washes of boracic acid, alum, dilute nitrate of silver, and finally used the mitigated caustic stick; potassium chlorate has been given internally, also ferr. cit. ammon. citrat. The patient is in good health, but the ulcers increase rather than diminish in numbers; they are painless.

SALIVATION IN PREGNANCY.

P. is attending a primipara, aged 28, 34 months pregnant, who has been salivated since the end of the first month. The case has defied all the varied drugs he has tried, and the textbooks he has consulted give little or no information. He will therefore be glad of any suggestion for the cure or alleviation of the distressing symptom.

THE PRESENCE OF VISITORS IN THE OPERATING THEATRE.

MEMBER B.M.A. writes: Is it not in accordance with the traditions of the profession that medical men shall be made welcome to the operating theatre of a public free hospital by their brethren upon the staff of the same? An instance in which the presence of uninvited local medical men has been treated as an intrusion suggests the advisability of a clear understanding upon the question. Young men whose professional duties are light are unwilling to find themselves in a state of rust and incompetence, and appreciate the opportunities for observation afforded by a hospital.

"We agree with our correspondent that any member of the profession desiring to attend operations at a general hospital should be received as a visitor, not as an intruder. He should if necessary make himself known to the operating surgeon or to some other member of the surgical staff in the theatre, and should ask leave to watch the operations; and he should be careful neither to stand too near the sur-

geon nor to take a place that can impede those who have the care of the case or those students who are present at the operation. A good surgeon likes to have his skill seen and understood, and is glad that the lessons to be learned from the operation should not be lost for want of an audience. Such operations as ovariectomy, which may involve the use of a small theatre, and special precautions for the prevention of infection, can hardly be considered as free to the profession. But as regards the presence of members of the profession at the usual operations of a general hospital, we believe that the interests of the hospital and the advancement of surgery demand that visitors should be made welcome, and to treat them as intruders is neither good policy nor good manners. They on their part must be careful to remain outside the immediate circle of the surgeon and his assistants, and to stand or sit where they cannot obstruct the view of the students.

FOREIGN HOMES FOR INEBRIATES.

F.R.C.S. asks if there are any homes for inebriates abroad where dipsomaniacs can put themselves under restraint for a year or two, and be thoroughly and efficiently looked after; or if there are any practitioners abroad who will undertake the management of such cases. The great difficulty is to induce dipsomaniacs to put themselves under restraint in homes in England, and he thinks if it was a question of going abroad the difficulty would be much less, in the same way that men while at home will do any kind and any amount of menial work abroad.

"* We cannot recommend individual practitioners or special homes. To advise English patients to place themselves under restraint in other countries involves serious responsibility.

ANSWERS.

GALLICUS.—The conditions under which medical practice is permitted in France will be found briefly stated in the Educational Number of the *BRITISH MEDICAL JOURNAL*, September 7th, 1896, p. 626, and more fully in the Educational Number for 1894, September 1st, p. 584.

A MEMBER.—The fourth edition of Professor Lombroso's *L'Uomo Delinquente* was published, according to its title page, at Turin, in 1890. A French translation, however, which purports to be made from the fourth edition, bears date 1887. As far as we are aware the work has not been translated into English.

A-KTONE will find an account of recent work on the chemistry of the carbo-hydrates in *Wat's Dictionary of Chemistry*, or more briefly in *Halliburton's Essentials of Chemical Physiology* (London: Longmans, Green, and Co. &c.), and also in *v. Jaksch's Clinical Diagnosis*, translated by Dr. Cagnoy (London: Charles Griffin and Co. &c.). The paper on creatinine alluded to is not yet published.

I.R.C.P.—We may refer our correspondent to the article on Degrees for Practitioners published in the Educational Number of the *BRITISH MEDICAL JOURNAL* of September 7th, 1896, p. 610. We are not acquainted with any university in the United States or Canada which would grant the degree of M.D. "without other than a clinical examination." We believe that most of the "Diploma Mills," as they used to be called in United States, have ceased to operate, their products being now generally esteemed worthless.

M.R.M. Assoc.—1. There is a large number of medical practitioners in New Zealand in proportion to the population. 2. A Branch of the British Medical Association is in course of formation in New Zealand, and Mr. Murray-Aynley, of Christchurch, N.Z., is acting in the matter. 3. Our correspondent, being a member of the North Wales Branch, cannot communicate his departure to the Honorary Secretary, D. Jones Morris, of Portmadoc.

TREATMENT OF GOUT.

J.A.—Dr. A. H. Garrod, in his *Treatise on Gout and Rheumatic Gout*, writes of Laville's tincture as follows: "It is stated to be a peculiar preparation of colchicum and colchynth, and to be free from colchicum, but, unfortunately, no stress can be laid upon such statements in regard to secret medicines." He states that it resembles colchicum in its action, and adds: "I do not think the moderate use of Laville necessary very in chronic, but it is its reckless employment which is to be so much deprecated." (2) An article on Piperazine, by Dr. John Gooden, was published in the *BRITISH MEDICAL JOURNAL* of June 16th, 1896, p. 1001. Abstracts of foreign papers on its use will be found in the *Abstracts of the Journal* for 1895.

HOT SALT WATER BATHS.

PUTERMAN writes: In reply to "M.D.'s" query (in the *BRITISH MEDICAL JOURNAL* of October 16th) for the best substitute for hot salt water baths at home, I think he will find "Broad Salt," from Droitwich, a most satisfactory substitute. It can be obtained of local agents at 3s. per hundredweight, or of the manager of the Droitwich Salt Works by the ton. About 1 pint to 12 gallons of water makes a good bath, and if the salt is put in a loose calico bag impurities are kept back, and patient and bath are preserved from any accidental grit. It dissolves quickly in hot water. I have so employed it for years.

F.C.W. writes: In reply to "M.D.'s" query in the *BRITISH MEDICAL JOURNAL* of October 16th, the Great Eastern Railway Company deliver sea water from Lowestoft at 6d. per 3 gallons, or a good substitute is Tidman's sea salt dissolved in rain water.

STROPHANTHUS.

DR. C. H. FRANK (Banstead, Surrey) writes in answer to Dr. Sherrill's queries as to strophanthus, the following facts, culled from notes of Francesco T. R. Fraser's lectures, may be of service. The seeds contain a glucoside, which is the active principle, and which is very soluble in water.

The drug has a powerful effect on striped and voluntary muscles; it produces irregular twitchings in involuntary fibres. The muscle then becomes more and more tense, until a state of tetanus is attained, when it is then acid. The action upon the heart is much more rapid than on other muscles. Strophanthus is probably the most active local agent known, more than ten times so than aconitine, in the frog. It has only a trifling action upon the blood vessels. In small doses, besides increasing the contraction of the heart, the diameter of the ventricle is also increased; hence there is a larger amount of blood propelled into the aorta. The spinal cord is faintly affected; a little sensory part may be brought about, and anaesthesia of the cutaneous can be produced. As regards its therapeutic uses, strophanthus may be given in the same cases as one would give digitalis, with the exception of hæmorrhages. On account of its being almost devoid of action upon blood vessels, the drug may be useful in certain cases in which one would hesitate to give digitalis, because of the latter's power of producing cumulative effects, because of its great constancy, whereas digitalis there is the possibility of the formation of several toxicine bodies.

NAIL BITING.

DR. W. WILBERFORCE SMITH (London) writes in reply to a query in the *BRITISH MEDICAL JOURNAL* of October 16th: My experience is as follows: It is no mere habit, but belongs to a group of habitual purposeless, fidgety movements—such as contorting the facial muscles, grunting, picking off the skin above the roots of the nails, etc. Such movements are controlled by the will only so long as attention is fixed on preventing them. Nail biting and finger picking are continued by young ladies who are ashamed of the resulting disfigurement. It is chiefly noteworthy that such movements are mostly associated with marked general muscularity, often of a wiry kind. They belong to an important larger group which I classify for myself as muscularity with neurosis. To remedy a tendency to nail biting, a fuller daily exercise of the unsatisfied muscular system is essential. To stop the fidgety movement let some more adequate movement be immediately practised, such as going upstairs.

ANOTHER MEMBER writes: I myself was quickly, safely, and pleasantly cured of the habit. The remedy was very simple, namely, a bribe of half-a-crown from an old lady if I did not bite my nails for a month. I honestly won the money, and have never had the slightest inclination to bite my nails since. Perhaps a larger dose of silver or even one of gold might be required in some cases.

NOTES, LETTERS, Etc.

T. writes: In your obituary notice of Dr. Thomas Groom, of Whitechurch, that gentleman "is said to have been the oldest medical practitioner in Shropshire." This is not quite correct, as there is happily living at Much Wenlock Mr. William Penny Brookes, F.R.C.S., who in August last entered on his 87th year.

We have received some further copies of the circular from W. Coleman, Norwich, of Coleman and Co., Limited, suggesting to medical men that they should take up debentures in that company for the sale of various preparations of meat extract. We are authorised to state that the firm issuing these circulars is not in any way connected with J. and J. Colman, of Norwich.

"LENNOX"—A DISCLAIMER.

MR. LENNOX BROWNE (Mansfield Street, W.) writes: Will you be so good as to publish this disclaimer of any identity between myself and the individual who answers questions on diseases of the throat, nose, and ear in the pages of the *Echo*, for, in spite of a protest from me published in that paper, and of disclaimers kindly admitted in your medical contemporaries, there is hardly a week passes that I do not receive a letter indicating that the confusion still exists in the minds of both patients and of professional confrères.

"* We publish the above disclaimer with pleasure. No one could imagine that Mr. Lennox Browne would prescribe for patients gratuitously in the columns of a halfpenny newspaper. The use of the word "Lennox" is calculated to deceive an ignorant public, and to make them believe that they are being advised by a duly qualified surgeon, but there is, unfortunately, no copyright in a "personal" name.

"LENNOX."

We have received what purports to be an answer to the comments we made last week upon the practice of this person, but as the communication is unsigned it cannot, of course, be dealt with.

ARTIFICIAL FEEDING OF INFANTS.

DR. PERCY BOULTON, M.D., etc. (London, W.) writes with reference to a paragraph on p. 704 of the *BRITISH MEDICAL JOURNAL*, September 25th, 1896, that it is not known to him that in Germany Beckert's system of sterilising milk for artificial baby feeding is as simple and as near perfect as possible. The whole of the milk required for a baby during a long journey can be prepared beforehand by any intelligent person. Each bottle contains sufficient milk for one feed only. It is used by removing an India-rubber disc and placing a teat in its stead, and the baby sucks direct from the bottle. The paraphernalia consisting of bottles, discs, wire bottle frame, and a tin pan, can be got at any tin in North Germany.

"WHAT A FASHIONABLE DOCTOR MARKS."

UNDER this heading a paper bearing the credited name of F. H. has lately published some strange revelations. The F. H. man constituted a "prominent specialist on certain diseases." There were thirty patients in the waiting-room; the fee was five guineas; and the F. H. man was told (by the history that the prominent specialist saw fifty patients daily at home, besides visiting fifteen or twenty more. He also states—but this does not appear to be on the basis of authority—that "many patients pay ten, twenty, and fifty guineas for a consulta-

SOME CLINICAL OBSERVATIONS AND PROFESSIONAL REMINISCENCES,

*Being the Presidential Address to the North-West London
Clinical Society on Wednesday, October 30th.*

By SIR RICHARD QUAIN, BART., M.D., F.R.S.,
President of the General Medical Council.

My good friend Dr. Cagney has by some magnetic influence induced me to address you this evening, which, being my seventy-ninth birthday, I might have spent by my own fireside. I may tell you that to-night.

CHOLERA.

To begin, then, with a few words of a personal character, I should say that in the year 1831 I became the pupil of an Irish surgeon-apothecary in Limerick. It was the year of the invasion of cholera. I recall one incident which impressed me. When my master had gone out in the morning, an old gentleman, between 70 and 80 years of age, called. He said: "Mr. Quain, I think I am very bad. Can you give me something? my bowels are bad." I said: "I am afraid you have got this disease." I gave him the routine remedy of that day. This varied, but probably at that time it was what was called "Ponsonby's drops"—a solution of camphor in spirits of wine, introduced by Lord Ponsonby, then Ambassador at Vienna; and I believe that and cold water did as much good in cases of cholera as any of the remedies that had been tried for it. The leading physician of the day in Limerick was Dr. Lyons, and his invariable practice was to give half a drachm of calomel and a couple of grains of capsicum, followed by further doses of calomel. My master being unable to go and see the old gentleman to see how he was, I knocked at the door and inquired, and the answer was, "Sir, he died an hour ago." That was a shock for a pupil fresh from school, who had been talking to this old gentleman at noon, to find that he was dead at six in the evening. The disease was very violent in Limerick at the time. It was limited to a district. This brings me to a very interesting and remarkable point. Why is it that we are protected, and that cholera is prevented from invading us? It is very much owing to the researches of a man, probably hardly known to any of you—Dr. Snow. He it was who pointed out that cholera was propagated by polluted water. This conclusion was the result of close research, Snow's investigations being opposed by such eminent men as Dr. Baly and Dr. Gull. They did not believe that cholera was thus propagated. At last there occurred a very bad attack in the neighbourhood of Golden Square, and the Broad Street pump became historical. Snow found that the people who drank water from that pump suffered from cholera, but those who did not, and took other water, escaped. An old lady and her niece migrated to Hampstead from this district, and died of cholera. There was not a case of cholera at Hampstead, but Snow showed that these good people had the water sent to them daily from their favourite pump at Hampstead. Nothing could be more confirmatory of the fact that cholera was propagated by poisoned water. These researches were extended by Sir John Simon and his able lieutenants, Drs. Parkes and Netten Radcliffe. Yet to-day possibly nine-tenths of the people now living do not know of Dr. Snow. There is no memorial; no monument. His name is unknown; but I hope, before I leave this earth, I shall secure something in the shape of a memorial to him. Probably the best of all would be, on the Thames Embankment, a granite fountain with the inscription that Dr. Snow had saved millions of lives. He was a graduate of the University of London, a member of the College of Physicians, and lived in Savile Row. He died at 50 years of age. He was a most unobtrusive man, and is best known as having written on chloroform and anaesthetics. We found memorials to all classes of people, and he is forgotten. He has been instrumental in saving the lives of

millions. Had he been a successful general, responsible for the deaths of thousands, he would have received a peerage and a pension.

THE GROWTH OF MEDICAL SOCIETIES.

In my early days there were only four societies of this character in London—the Hunterian, the Medical and Chirurgical, the Westminster, and the Medical Society; now there are twenty. The extension of these societies is a proof of their value, otherwise they would not exist. It would be well if they could be more concentrated. It was suggested at one time that the Medical and Chirurgical Society should be a great centre for all other societies. I have in my possession a series of rules and regulations that were prepared to convert the Medical and Chirurgical Society into the Royal Medical Society of London. It did not succeed, and so we are now divided. The Pathological Society was the first branch from the Medical and Chirurgical Society. It was suggested that there should be pathological evenings at the latter, but the idea was abandoned. The Pathological Society was then founded, and it has had great success. I was one of the founders. The real founder was a man whose name probably you have never heard, Dr. Bentley. That is another name that I hope to rescue from oblivion. Dr. Bentley was a Guy's Hospital man in practice in the City, and having seen in the Dublin Pathological Society the advantage that would result from such a Society in London, he applied to a number of physicians and others connected with hospitals. They embraced the suggestion, and the result was the Pathological Society of London. Dr. Bentley did more, for he was the founder and originator of the Victoria Park Hospital.

Turning to the clinical societies and their work, I do not know anything more important than the application of knowledge to the relief or cure of disease in the wards of hospitals. I was reading the other day an observation of Mr. Thistleton-Dyer, of Kew, with reference to botany. He finds that the study of botany is now unhappily almost a thing of the past, that the modern university student of botany puts his elders to the blush by his minute knowledge of some small point in vegetable pathology, but he can tell little as to the contents of a country hedgerow, and if an unfamiliar plant is put in his hand he is very much at a loss how to recognise its family. Now these clinical wards of the hospitals very much resemble the hedgerow, and people who devote themselves exclusively to limited investigations would feel as much at a loss in the rows of beds in a hospital as the man did in the hedgerow of Mr. Thistleton-Dyer. I therefore urge above all things the study of all the phases of disease and its treatment. It is very well to borrow the ideas of those devoted men who work at special subjects, it may be in anatomy, physiology, or pathology, but we must seek to apply this valuable knowledge practically. It is our whole study, and our whole aim and object, to prevent or cure disease, and nothing contributes to this desirable end more than a clinical hospital, where you can study the phases of disease, and bring your remedies to bear upon their treatment. I therefore heartily wish success to your hospital and to your society.

ALBUMINURIA AND MERCURY.

Now, gentlemen, I have met very many remarkable cases in my lifetime, and I would like to bring some of them before you. I particularly refer to cases of albumin in the urine. It is unfortunate that the name of "Bright's disease" was given to the presence of albumin in the urine. It scares everybody. "It is Bright's disease," they say. That is a specific thing for which there can be little help. That is, as I say, a great mistake. I had a case brought before me of a gentleman, a very active literary man, whose whole life was work. He lived generously, he worked hard, and the malady for which he came to me was the presence of albumin in the urine. The urine contained a marked quantity of albumin; there was a specific gravity of about 1015, and there were a very few casts. I recommended him to get his liver unloaded by small doses of calomel. He found so much benefit from this, that he kept a little ivory box in his pocket with a certain number of half-grain calomel pills, and whenever he felt his digestion out of order or a headache,

he took one. That treatment went on for 25 or 26 years. During all this time he was in most active work, yet he had copious deposits of albumin in his urine. But now here is a very remarkable point. This patient at one time developed an indurated growth in the form of a ring round the corona glandis. There was no abrasion, no swollen glands.

Mr. Henry Lee saw the patient with me. Mr. Lee said, "Upon my word, I do not know what to make of it, but I think he had better be treated as if he had syphilis."

We agreed to administer blue pill every night, and this gentleman being a man of tremendous energy, very go-ahead in everything, we found that after two or three days he was taking 25 grains of blue pill a day. Not only that, but he also practised mercurial inunction. He was so eager to get rid of this filthy thing, as he called it, that he actually exposed his parts to mercurial vapour, and he did get rid of it. All this mercury did not affect the albumin in the slightest degree; it did neither good nor harm. Mr. Lee said he did not think it would do harm, because in a case of albuminuria, in which he gave a mercurial bath, the albumin was diminished. I want to impress this one point upon you: that there has been a morbid feeling as to the impropriety of giving mercury in albuminuria, dropay, and so on. It may sometimes do harm, but I am quite sure of this, that mercury is often invaluable. I believe it relieves the congestion of the abdominal organs, the liver and kidneys.

The case I have just related is not an exceptional case. I was consulted by the parents of a young lady, 18 years of age, who when menstruating bathed in the sea. The menses stopped and oedema set in. This happened in May. I saw her in the following November; she had albuminous urine and general oedema. I did not quite see my way to using mercury, and I recommended hot-air baths, salines, and so on, but they had no effect. At last I determined to try mercury, and I gave her 3 grains of Plummer's pills—which would be equivalent to nearly three-fifths of a grain of calomel three times a week; she took also some citrate of soda. By degrees all the oedema disappeared and the albumin got less. It never left her entirely. She got well, and was under my observation for eight years. I should say that she took 3 grains of Plummer's pill three times a week for a year, then twice a week for a long period, and then once a week. She went to the Cape of Good Hope, and when she came back she became engaged to be married. Unfortunately, after being married two years, she had congestion of the lungs following influenza, and died.

What I wish to impress on your mind is that under certain circumstances mercury is a most useful remedy in albuminuria, and it should not be avoided. In fact, the objection to it originated with Dr. Blackwall, of Exeter, who wrote in the year 1818 or 1820 on dropay connected with kidney disease. He very nearly anticipated Dr. Bright. If you read the two side by side there is very little difference. At any rate, Dr. Bright's name unfortunately was given to mere albuminuria; and it is very difficult to say what "Bright's disease" really means. On one occasion an Irish lady had heart disease, congestion of the kidneys, and a good deal of albumin in the urine. I saw her with Dr. Richard Wheeler, and he let drop the words "Bright's disease." "Oh! have I Bright's disease?" "Well," she says, "I shall see Sir William Gull, and I will ask him." Sir William Gull came. He saw the lady, and after a consultation she said: "Now Sir William, have I Bright's disease?" "Madam," he said, "what is Bright's disease?" It was an instance of his tact; he evaded the subject, and went away. After he had gone, she said: "But he never told me." "Oh," I said, "he asked you what was Bright's disease, and you did not tell him." "How should I know?" said she. "Well, you don't know, and neither does he."

Speaking of Bright's disease, I was sitting next to Dr. Bright in one of the early meetings of the Pathological Society, and I happened to have the drawing, now in my hands, which I have given to the College of Physicians. It represents two distinct forms of Bright's disease—the large white and the contracted. I said: "Dr. Bright, which of these is Bright's disease?" "Oh, well," he said, smiling, "I will take them both." It is very unfortunate that the name "Bright's disease" should be used indiscriminately as it is, because it is applied to many cases which have nothing of so-called Bright's

disease about them. I will mention an illustration of that. I had a patient, a lady, who asked me to look at her boy, the only son and heir to a very large fortune. He was quite a skeleton, a wretched little fellow, 6 or 7 years old. I examined his urine, and I was very much surprised to find both sugar and albumin. I told her so. In the course of the afternoon her husband came and said: "You have shocked me about my boy; you find sugar and albumin in his urine; could that have arisen from eating sugar?" I said: "What does he eat sugar for?" He said: "His uncle consulted Sir William Gull about him, and Sir William Gull said as the boy was constipated, that he should eat plenty of bread and brown sugar." The boy liked the prescription, and indulged immensely in bread and brown sugar—any quantity. Of course this diet was stopped, and the boy got well. I lost sight of him for five or six years, and then he was brought to me from Eton. The servant who brought him said: "Eton is broken up, there is some scarlet fever there and floods, and the master desired me to bring the boy to see you. He has a sore throat and is not very well." I examined the boy, and found he had a great quantity of albumin in his urine. His throat was sore, but he had no rash; his figure was like a pouter pigeon, the abdomen marvellously distended. I said, "What have you been doing?" "Oh," he said, "I have been eating too much." It turned out that he had two hampers a week. Two other boys in the same house with him had two more containing pies and tarts, and all sorts of things, and this poor fellow had an enormous liver. I was very shocked, but his father telegraphed from Ireland, "Send him home: I have a very good doctor here." He went to Ireland, but the doctor there said, "Take him back again; I can have nothing to do with him." So the father and mother came over and brought him here, and I looked after him for a few days. The next thing I heard was that he had fallen from his horse when riding in Rotten Row, and was taken to St. George's, and there he was under the care of Mr. W. Rivers Pollock, the house-surgeon, and Mr. Dent. Of course the father and mother were very much alarmed. They asked me to go and see him. Mr. Dent and Mr. Pollock said: "We are sorry to tell you, but he has fracture of the orbital plate, and hemorrhage all round the eyes, with albuminous urine. We thought it a very serious case." The boy was treated with simple diluents, and the albumin gradually disappeared. After a while he got better, and was taken to the hotel where his parents were staying; then when he returned to a diet of ordinary fare the albumin returned. The parents were so anxious about it that I had a specimen of the urine three times a day sent to me to be analysed, and each time with a bill of the fare of what he had eaten before. I tried to discover what suited him and what did not. I found that after a luncheon of cold chicken and tongue there was a great quantity of albumin. However, he got better. He went to Ireland, and the next thing I heard of him was that he was at Cambridge, and very fortunately he came under the care again of Mr. Rivers Pollock, who was then at Addenbrooke's Hospital. The boy was quite well, and was the master of the harriers. He grew into a healthy young man and is now married, so that you see albuminous urine does not mean a serious Bright's disease that cannot be cured.

DISORDERS OF THE LIVER.

This case, gentlemen, brings me to the subject of disorders of the liver. Now, when we remember that every animal in creation from the highest to the lowest has a liver, or something equivalent to it, it must be an organ of very great importance, and I believe sufficient notice is not taken of it. I have seen myself a sequence of sugar and albumin and urica appearing alternately in the urine. I wish I were skilled enough in organic chemistry to explain this, but it is not within my power to do so. I will give you an illustration. It was formerly said that the proportion of urica you may find in the urine depends entirely on the quantity of urine that is passed. On one occasion I was consulted by a gentleman living in the Temple. He was a young man under 40 years of age, with large means. I saw him with Mr. Savory—afterwards Sir William. He said: "This man is dying; I do not know what is the matter with him. All his family die in this way." The patient was a good-looking fellow, whose complaint was: "I cannot do anything,

doctor; the fact is I am no use." "Are you very weak?" "Yes, I am very weak; I do not care to walk or to do anything." I said: "What do you eat?" He said: "I like vegetables. I take little but vegetables and very little stimulant." I said to Savory: "How about his urine?" He said: "His urine is all right." I said: "I should like to have some of it." It came to me, and I found that it had a specific gravity of about 1035, and was loaded with urea. The next meeting I had with Savory I said: "I think I have a clue to it." When asked if he passed much urine, he said he was weary of performing the act of micturition, passing from six to eight pints daily.

Now that single case upset the whole theory that when there is excessive urea it is owing to the diminished secretion of urine. In his case the secretion was enormous. He was well purged with colocynth and blue pill, and got well, this treatment being pursued for years. That case led me to think how much the liver had to do with the excretion of urea. A French writer, Dr. A. Martin (Paris, 1877) has pointed out that the amount of urea in the urine is very often a test of diseased or congested condition of the liver. I have found that information very useful in like cases. People come to you and say: "I am so depressed; I am so languid, I can do nothing." Examine the urine, and in nine cases out of ten in that condition you will find excessive urea. Put the liver right, and you will generally cure the patient.

The late Mr. Carlyle was a patient of mine. As all the world knows, he was a man of great judgment and great power of observation. With regard to himself, the only remedy I could ever get him to take was grey powder. He lived to 82 or 83. Grey powder was his favourite remedy when he had that wretched dyspepsia to which he was subject, and which was fully accounted for by the fact that he was particularly fond of very nasty gingerbread. Many times I have seen him sitting in the chimney corner smoking a clay pipe and eating this gingerbread. He overcame the difficulties incident to this habit by his grey powder, which did him much good.

A very interesting and remarkable case was that of a nobleman 63 years of age, a man of great intelligence, of very amiable character, and clever. He had been a patient of Dr. Lombard, of Geneva, the physician who first indicated a difference between typhoid and typhus fever. Lord A., as a boy at College, had acute rheumatism and endocarditis, and it was many years after that that he first came under my notice. I found him in the month of November suffering from a mild form of influenza. It was on one of those foggy days by which we are so much afflicted, and he said, "I won't stop here; I am going to the South of France, but I should very much like to see Bence Jones and Dr. Watson before I go." When they met, Bence Jones said, "Well, that man ought to have died long ago; I told him so." True enough, this gentleman always met Bence Jones afterwards by shaking hands with him and saying, "Jones, you may shake hands; I am not a ghost." However, Drs. Watson and Bence Jones agreed that he should go to Paris, and he went. He was under the charge of Dr. David Christison, the son of Sir Robert. He arrived at Paris in the evening, and the next day but one I got a telegram: "Lord A. is very ill; pray come to-night." I went over and arrived in the morning, and met Dr. David Christison. He said, "He is very ill; he has congestion of the base of his left lung." I knew at that time he had albuminous urine; he was suffering from mitral valve disease with some enlargement of the heart. Nothing could be more unfavourable than his aspect, for he was very ill. Sir Joseph Olliffe had called in Baron Louis and M. Trousseau; they prescribed a mild dose of grey powder and antimonial powder. Trousseau said that he should take nothing beyond "urine."

As this was contrary to the suggestion I had made to Dr. Christison as to the importance of maintaining his lordship's strength I was sent for. Seeing how low the patient was I immediately prescribed for him the *mistura spiritus vini Galii*. I believe this to be a valuable remedy in many cases. In the first edition of the *Pharmacopœia* published by the General Medical Council it was left out, but it has since been restored. I also applied a blister. When Trousseau arrived, between 10 and 11, with Baron Louis and Sir J. Olliffe, I said: "Following his lordship, I felt it neces-

sary to give him brandy." "What?" said Trousseau. "do you cure Bright's disease in London with brandy?" "No, we do not," I replied; "but I should like to keep his lordship alive while your remedies are doing him good." As the result of the treatment Lord A. got much better, and I went away after eight days leaving him better. Baron Louis then came to see me, and was rejoiced to find how well he was. He, however, said: "I know at the Hôtel Bristol there is some magnificent burgundy. He must be tired of the brandy; give him some burgundy." The patient took it for three days, and then his kidneys stopped secreting and there was more albumin than ever in the urine. I was recalled, went on again with blue pill and squills and so on, and Baron Louis was sent for. I said: "M. Louis, this is the effect of the burgundy." "No," he said; "it is the over-feeding; you have given him so much to eat. What will you do?" I said: "We will give him blue pill." He said: "Do you cure Bright's disease in England with blue pill?" I said: "I do not know that anything will cure his lordship now." Fortunately, the blue pill did good; the dropsy went and he got very much better, though he remained extremely low and had aphthæ of the mouth. He had a very sore back; though he lay on a water bed, a portion of the sacrum was exposed; but, notwithstanding that, he got better, was moved, and finally came home to his country house in England, and went on extremely well for the remainder of the summer. But in November he went out for a drive on the Downs; he got cold and had pleurisy. He got through it, but eventually he died suddenly at the end of March from heart disease. However, he might have been well now if it had not been for this undue exposure on a cold winter's night. M. Trousseau introduced this case into one of his clinical lectures, winding up with the sentence, "Had he been a Frenchman he must have died."

SOME REMARKABLE CASES.

Passing now to one or two rather remarkable cases, I was asked to see a gentleman in Harrington Square, aged about 40, with Mr. Claremont, of Hampstead Road. He said, "This is a very curious case. The man has a morbid impression that his bodily smell is most offensive. He is engaged in business as a solicitor. He meets his partners, and conducts business with them, but he has tact to hide it from them." The patient was in his bedroom, dressed exquisitely cleanly. He said, "Well, sir, I am very sorry to bring you here. My smell must be most offensive to you; in fact," he said, "I am afraid your horses will feel it at the door." That was his strong impression, and even the pictures in the dining room were covered up to keep them from this offensive master. I examined his abdomen, and found a swelling in the iliac region. I said to Mr. Claremont, "He has a fecal accumulation there." He said, "All my smell comes from there." Mr. Claremont subsequently had to open a very foetid fecal abscess. We know that there is nothing more intolerable than the stench of such an abscess. But how will you account for his impression? There, however, is the fact: Mr. Claremont and I witnessed it. He was perfectly cured by the discharge of this abscess.

There was a second case of another kind. I was asked by Dr. Walsh, who afterwards left London, to see a patient with him, a man of rather eccentric habits. It was said that he had been shut up for three or four days, and that when the door was opened he was found lying on the bed quite insensible. No food was to be seen beyond the remains of a mutton chop which he had provided for his parrot. We were told that he was always talking about "a block," and the fear of this block prevented him from eating. We brought him to, but he died in the night. A post-mortem examination revealed that he had a lump of faeces in the rectum as hard as iron—there is no knowing how long it had been there. It was as big as a man's fist. It was perfectly true that the poor man had a block, and he had starved himself to death in consequence.

I will now mention a case or two of another kind. I was required by Mr. Wakley, the coroner, to make a post-mortem examination of a man whose story was this: He was a woman.

He came in to his dinner, went to the scullery, washed his

I had more than 100 telegrams from him during the illness, and went 4 times to Paris.

hands, and when he came out he said to his wife, "It is all over, I have taken poison." "What have you taken?" "Arsenic." She carried him off to the Western General Dispensary, where my excellent old friend, Dr. Humby, at that time was resident medical officer. He was out, but there were two young pupils of his there, very good fellows, who thought it was a very important case, and they would treat it pretty actively. They gave him tartar emetic, pumped out the stomach, and pumped oxide of iron into it, and a good many other operations they performed. The poor man was extremely ill, had vomiting, with profuse painful diarrhoea, and died in twenty-four hours. The beadle of the coroner went to the chemist, and said, "How did you come to sell this man poison?" He said, "I sold him no poison; I thought he was off his head when he came." "What did you give him?" "Oh, I gave him some alum and cream of tartar, and labelled it 'poison.'" He swallowed this. When I made the *post-mortem* examination, to my amazement I found a very great deal of arsenic in the stomach. That was rather puzzling. I said, "If it is in the stomach it ought to go further down." So I searched the intestines, but there was no trace of arsenic anywhere. The simple explanation of it was this: These two young fellows, horrified to find the man had died without taking arsenic, pumped some into the stomach. Mr. Wakley was a very stern man, but of most amiable and excellent disposition. He said, "Now, Quain, this is a dreadful thing. These people might be declared guilty of manslaughter; at any rate, it is a great contempt of court. I will commit them." I begged him not to do so, saying, "You will ruin them. I am sure it was all well intended." Finally the coroner was persuaded to let the matter drop. But it was a very remarkable case. I might have had some hesitation at first about it had not the quantity of arsenic been so enormous. I should mention that there were two intussusceptions in the ileum.

THE GENERAL MEDICAL COUNCIL.

I have occupied a great deal of your time, but will you excuse me, as President of the General Medical Council, saying to you a few words on that much abused body? I have been a member of the General Medical Council more than thirty years, and I feel assured that body will have an enormous influence for good on the medical profession hereafter. I remember that when general political reform was in the air there was also a question about medical reform, and the great cries of that day were, "Let the profession govern itself, with uniformity of qualification and reciprocity of practice." At that time, as you may know, people educated in Ireland were not qualified to practise in England and Scotland, and *vice versa*. Uniformity of qualification has hardly yet been reached, but reciprocity of practice has been fully established. That was asked for, and very many appeals were made to Government and Parliament for medical reform. Some people wanted very much, some wanted very little, and between the extremes what one Government proposed was that the Government should appoint the General Medical Council, and to have a Government stamp of registration—that is to say, to take the control of the medical profession entirely out of its own hands, and to give the fees that were paid altogether to the State as a tax. That was very much opposed, and was never carried, but the Government saw their way to a change, and the beginning of it was that a Board was constituted in 1832, called the Board of Health. At that time Sir Benjamin Hall, a very radical man in his tendencies and a homoeopath, was President. We went to him to ask him to give us a medical Bill. He said, "What do you want?" He said, "Do you mean to tell me I am not to go and consult anybody I like?" We answered him: "Yes, consult whom you like. You may go to the greengrocer; we have no doubt he is accomplished in simples, but we won't allow him to be called Dr. Green." He assented to that, and said: "Let me remind you how it was when Lord Althorpe was Chancellor of the Exchequer" and he told us this story: There was a suggestion before the House that nobody should be allowed to prescribe unless qualified, and Lord Althorpe said: "The last financial statement I had to make, I was coming down to the House. I was suffering intensely from gout, so that I thought of turning back and postponing it, but," he said, "I went into a chemist's in Parliament Street, and he gave me

some medicine that relieved me immediately. Am I not to get such a thing as that?" he said, "the thing would never be tolerated." Well you know that tradition exists in the House of Commons, and I believe nobody would ever there say: "You must prevent people from prescribing." You may prevent them from calling themselves or pretending to be doctors, and I believe in our Act we have enough to prevent that, and I trust whether we get further legislation or not we shall be able to prevent people calling themselves doctors and imposing on the public. That is quite as much as we shall get.

But with regard to the Council itself, if you have before you the names of the very distinguished men, from first to last, who have taken a share in it—Brodie, Green, Watson, Burrows; and men from Edinburgh—Christison, Syme; and from Dublin—Stokes and Corrigan—men of the very highest type, and those equally great men, their successors—I believe these men have always worked for the advantage of the medical profession; but they have been prevented by jealousy, one body of another—rivalries—what Sir Dominic Corrigan called the "battle of the shops," and have never had free scope. By degrees a better feeling has come about, not by legislation or by prosecutions, but by what Mr. Syme called "moral suasion." I believe that the bodies are coming round to see that it is most desirable for their own interests, and for the interests of the profession, that they should have honest and sufficient examinations, and that in a little time you will see, under the guidance of the General Medical Council, by their visitations of examinations and by not proceeding harshly or quarrelling, a very great advance will be made in the education of the medical profession. When I first joined it I remember the examination of the College of Surgeons extended over one hour—half anatomy and half surgery; now the conjoint examination is spread over more than thirty-two hours, so great is the advance; and this examination must of course lead to improved education. The period of study was at one time two and a-half to three years; now it is five. I believe very much of this change is due to the General Medical Council. They have had great difficulties to meet—the "battle of the shops" and so on; but I believe you will all live to have the government of the profession in your own hands. We are compared sometimes with the lawyers, but if you look at the solicitors they have no power. However infamous a man's conduct may be, they must bring him before a court of law. We need not do that. The highest court has pronounced that if we declare a man's conduct "infamous," there is no appeal. It is so, and therefore it makes us extremely careful in coming to a decision on that point. But there are degrees of disgrace less than infamy which ought to be corrected. This should be done by the medical authorities in their by-law. At this moment I have before me the case of a grocer in Liverpool who gives with a quarter of a pound of tea a ticket to three doctors, and any one of them can be called in. These doctors are the hirelings of this man, and he says to his customer: "If you buy a quarter of a pound of tea a week, or for two or three weeks, you will be entitled to receive medical assistance." Can greater prostitution of an honourable profession be? Again, with regard to the fee of £5 paid for registration, it compares favourably with the stamp tax of £80, and £25 paid by a solicitor on admission, besides the annual tax of £9 for the certificate.

There are many other things I might have said, but I will not detain you longer, and I thank you very much for the attention you have given me.

PROFESSOR RIEDEL, of Jena, has been called to the Chair of Surgery at Göttingen in succession to Professor König.

We are pleased to note that Dr. Urbano Orad, the medical officer of the Spanish army whose death in Cuba was recently announced in the BRITISH MEDICAL JOURNAL, is still alive and has nearly recovered from his wounds.

On Monday, November 4th, the President of Council of the British Medical Temperance Association gave a breakfast to a number of medical students in the Throne Room of Crosby Hall, Bishopsgate Street, London. Speeches were delivered after breakfast showing the advantages of total abstinence from alcohol, especially to medical students.

A DISCUSSION ON ACUTE LOBAR OR CROUPOUS PNEUMONIA; ITS ETIOLOGY, PATHOLOGY, AND TREATMENT.¹

I.—E. DOUGLAS POWELL, M.D., F.R.C.P.

Physician Extraordinary to the Queen; Physician to the Middlesex Hospital; Consulting Physician to the Hospital for Consumption, Brompton.

I much wish that, in response to the flattering invitation of the Council that I should introduce the subject of pneumonia for discussion, I could have reported some notable diminution in its mortality, some more strenuous measures adopted for its prevention and treatment. With our better defined knowledge of the disease, we are perhaps on the borderland of new methods, but to-day I must regard myself rather as commissioned to elicit evidence and information from many here well able to give both, and, by formulating the subject, to endeavour to bring out those points which most require elucidation.

TABLE I.

TABLE COMPARING DEATH RATE FROM PNEUMONIA AND TOTAL DEATH RATE 20 YEARS
MEAN ZYMOTIC DEATH RATE 3400 PER MILLION MEAN ZYMOTIC DEATH RATE 2800 PER MILLION

A glance at this table (Table I) will show that whilst in the last as compared with the preceding decade the death-rate from zymotic diseases has very greatly declined, that from pneumonia still holds its own at 24,000 and upwards; the mortality from phthisis has also been shown by the statistics of Longstaff in the same time to have diminished by about 18 per cent.,² yet pneumonia, the claims of which to classification amongst zymotic diseases have become much stronger of late, still frustrates our preventive and therapeutic measures.

Pneumonia stands out too with appalling conspicuousness in the frequency with which it attacks the maturely useful members of the community (Table II), one-third of its death-rate occurring at that period of life when the individual is in the zenith of working power for the family and the community, and apparently in the fulness of health and vigour, thus causing many an almost sudden bereavement in the midst of apparently unclouded happiness and prosperity. Pneumonia then is a disease which the Council has well selected for special consideration at this Congress.

Now, Sir, to describe the clinical features of pneumonia,

¹ In the Section of Medicine at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

² Longstaff's *Statistical Enquiries*, p. 233, taking the mean diminution at all ages.

its symptomatology, and rough pathology to an informed audience such as this, would indeed be impertinent waste of time. The striking incidence and stormy course of the disease have marked it out for observation from the earliest days of medicine; but neither will I spend time in alluding to matters of historical interest, for we have to deal with the disease of to-day in that light which the present phase of our knowledge reflects upon it.

TABLE II.

The etiology of pneumonia has always exercised the minds of thoughtful physicians, and many of the following statements regarding it are in accordance with current opinions:

1. The prevalence of the disease has long been observed to bear no direct relationship to severity of climate. Unlike bronchitis, its distribution has but little connection with mere latitude.

2. Nevertheless, taking a given climate such as our own, the pneumonia rate, contrary to our experience in its latitudinal distribution, shows a distinct and close relationship to seasonal periods of depressed temperature. A glance at Longstaff's statistical tables for the years 1873-82 will at once show this (see Table III).

TABLE III.

Weekly Deaths from Bronchitis and Pneumonia in London.

The grey shaded areas indicate mean weekly temperatures below 50°F. The black indicate mean temperatures below 40°F. Longstaff.

3. Changeableness of temperature, such as prevails at certain seasons of the year in our climate and in many other localities, has a marked influence in increasing the prevalence of pneumonia. We may safely accept the conclusions arrived at by Dr. Coupland and the late Dr. Sturges that "It is in the regions that are called temperate and in their exposed places that pneumonia is especially prevalent. When north and north-east winds prevail, when the configuration of a country is favourable to currents of cold air, in such places as Madrid, Genoa, Florence, Naples, Gibraltar (different in other respects, but alike in this), in the high plateaux of countries whose lowlands are strangers to the disease, as in Africa and Mexico, pneumonia finds its chief victims."

4. It is difficult, indeed impossible, to estimate in any statistical manner the important element of *personal imprudence* in the etiology of pneumonia; but it is an element that must necessarily tell with increasing force in those places (a) where the vicissitudes of natural climate are greatest, and (b) where, as in our crowded communities, exposure to frequent changes of temperature is a consequence of our social life and manufacturing and office labours. A better knowledge of hygienic laws may lessen this cause. He is a contemptible man who is always thinking of his own skin, but he is imperfectly educated and thoughtless of the purposes of life who refuses to take note of his health surroundings. My experience would lead me to affirm that at least one third of the cases of pneumonia as we meet with them arise from foolish and thoughtless disregard, especially by elderly people, who should be wiser, of simple precautions against chill. And it is in this regard that the fatalistic and, I believe, entirely inadequate view that we at all frequently acquire pneumonia as we acquire typhoid fever or scarlet fever or diphtheria by the reception of an organism is unfortunate, as tending to enhance carelessness. It is probable, as I shall presently point out, that we are always—no doubt more particularly so in epidemic seasons—in the presence and possession of pneumonic organisms; but it rests much with us whether we shall bring about the conditions favourable for their aggressive germination.

5. Apart from the evidence furnished by its prevalence at periods of seasonal lowness and variability of temperature, there is the experience of the fact that in a certain number of cases, estimated by Griseolle and Ziemssen at about 20 per cent., chill—that is, suddenly or rapidly depressed surface temperature—is an important element in the etiology of pneumonia.

6. The pathology of chill, the exact phenomena as regards temperature of surface and internal parts, vasomotor reactions and other nervous phenomena with which it is attended, and especially the relationship, encouraging or otherwise, which these phenomena bear to the viability and multiplication of certain microbic organisms, such as those of pneumonia, malaria, influenza, and possibly rheumatism and tubercle, is a subject upon which little has been done, and which would be admirably suited for experimental inquiry. Whilst an even body temperature can be maintained by warm-blooded animals under general conditions of extreme cold and warmth, it is very probable, perhaps clinically almost certain, that the compensatory powers of the organism can be surprised and defeated by sudden local exposure to change of temperature, and especially under conditions of depressed vital force. It is a common and very instructive experience how such exposure will produce severe nasal catarrhs, which, when thus acquired, are very readily transmitted to others by contagion.

7. As a complication of acute febrile disease, except in the hypostatic form, or from embolic causes, pneumonia most commonly arises at the period of low or subnormal temperature. This chart (Table IV) is of a kind with which we are all very familiar. I have elsewhere commented upon this incidence of specific diseases at low temperatures, pointing out that the most favourable temperature for the cultivation of most specific organisms is that at or rather below the normal temperature of man. (See Table V.) I shall again allude to this point presently.

TABLE IV.—Chart showing the Onset of Pneumonia Complication during Period of Depressed Temperature.

(a) The many synonyms that have been accorded to Fraenkel's pneumococcus since its recognition by himself and by Sternberg as a factor in pneumonia, and the many conditions under which it has been found are suggestive of a wider range of activity than can be accorded to any other organism of specific rank, although in this respect the bacillus of tubercle and the poison of syphilis may be regarded as coming near to it. For synonyms we have amongst others micrococcus Pasteuri (Sternberg, 1890), found in the blood of rabbits inoculated from his own saliva, micrococcus sputum septicæmiæ (Fraenkel, 1883), diplococcus pneumoniae (Weichselbaum, 1886), bacillus salivarius septicus (Biondi), lancet-shaped micrococcus (Salaman), streptococcus lanceolatus Pasteuri (Gamaleia).

(b) Originally found in the saliva the pneumococcus of Fraenkel, besides being almost constantly (about 80 per cent.) present in pneumonic exudation and sputum, has been found in 60 per cent. of cases of purulent meningitis,⁴ in about 20 per cent. of cases of ulcerative endocarditis,⁵ in about 25 per cent. of cases of otitis media,⁶ besides, as is to be expected, it is prevalent in joint, ear, meningeal and pyæmic complications of pneumonia. These several diseases have no clinical or pathological relationship to pneumonia. True, they are inflammations, but whereas pneumonia is *par excellence* a fibrino-corpuseular and non-suppurative inflammation, these have the common character of being all suppurative.

(c) The above-named inflammatory lesions are, however, rare as complications of pneumonia, although the pneumococcus is known to prevail in the blood, tissues and air passages during the attack. On the other hand, pneumonia has not been a frequent complication of them, with the exception of an unusual prevalence in Osler's cases of ulcerative endocarditis.⁷

(d) Fraenkel's pneumococcus is almost equally to be found in all cases of pneumonia, whether typically croupous or pythogenic, or influenzal.

(e) There appears to be a minority of cases in which Fraenkel's pneumococcus is not to be found, but in place of it Friedländer's bacillus, and in a still smaller number of cases neither of them, but another bacillus differing in character from both of them yet considered responsible for, and capable of reproducing by inoculation of pure cultivations, pneumonia with great certainty, namely, Klein's bacillus pneumoniae, found in the cases of the Middlesbrough epidemic.⁸ It would appear from Ballard's report that sewer gas emanations were responsible for this outbreak.

(f) Cultivations of these various cocci do not, when inoculated into animals, produce pneumonia with a certainty at all comparable to that with which tubercle bacilli produce tuberculosis, but more commonly cause some form of septicaemia, which has, perhaps, too easily been accepted as valid evidence of the specific properties of the organism.

(g) The frequent discovery—first by himself and Sternberg—of Fraenkel's pneumococcus in healthy saliva, nasal mucus, ophthalmic secretions, and the like is a very remarkable fact showing that even supposing this organism to be specific of pneumonia its presence is harmless unless the conditions be brought about under which its active and aggressive germination is promoted. I have long held the belief already expressed that we have in and about us samples of many sorts of diseases only waiting that opportunity for active onslaught which our imprudence or misfortune will sooner or later give to some one or other of them.

10. How far is pneumonia a disease brought about by condi-

tions favourable to the aggressive germination of an organism ever more or less present.

It seems then to me that Fraenkel's pneumococcus is only one amongst several micro-organisms presenting claims to be the specific cause of pneumonia, that it is inadequate as a sole cause to produce pneumonia, being found in other diseases and in healthy secretions, and that even if we can establish by further inquiry more firmly its specific character, or replace it by another microbe better equipped, pneumonia will still resemble such diseases as tuberculosis, erysipelas, acute rheumatism, tonsillitis, perhaps influenza, in requiring for its efficient etiology certain conditions of impaired vitality, local or general, to enable the poison to become aggressive. It is by ascertaining and avoiding these conditions that we may do much to prevent and to combat the disease.

Leucocytosis has attracted much attention of late. This table of six cases taken consecutively briefly records the present position of facts. We observe that the white cells are invariably increased in pneumonia—as in all pyrexias—during the fever stage, whilst the red cells are unaltered; that they are diminished below the normal with the critical fall of temperature, to increase again with relapses.

TABLE VI.

LEUCOCYTOSIS IN PNEUMONIA (Middlesbrough cases)

Cases	Date	Temp.	Red corpuscles	White	Result
Male at 22	Feb 7	104 °	4 900 000	12 120 red	Death
Right apex	" 8	99 °	4 900 000	1 - 300	Recovery
Left base	" 11	104 °	3 200 000	1 - 300	"
Male at 23	Feb 4	103 °	3 200 000	1 - 100	"
Right apex	" 16	98 °	4 550 000	1 - 450	"
Female at 24	Mar 30	102 °	3 200 000	1 - 280	"
Left base	Apr 3	98 °	"	1 - 450	"
Male at 26	Apr 27	102 °	"	1 - 250	"
Left apex	May 2	98 °	"	1 - 450	"
Male at 23	May 13	"	"	"	"
Double	"	101 °	"	1 - 70	Death
Male at 19	May 21	103 °	4 550 000	1 - 740	"
Right apex	" 27	98 °	5 000 000	1 - 450	"

In 23 cases sputum examined. Pneumococcus was found in all but no relation could be found between the number of cocci and the height of the temperature or the severity of the case. After the crisis the organisms were always few in number.

11. With regard to septic or pathogenic pneumonia, I have only one or two remarks to make:

In the first place, the disease in its essential minute anatomy is the same as croupous pneumonia, but the distribution is in smaller areas, more scattered, more limited to one side or lobe, more liable to metastatic changes of site.

Secondly, the temperature is from the first more fluctuating in character, and subsides, as a rule, with no critical fall.

Thirdly, the organism found in pathogenic pneumonia is still the same—Fraenkel's bacillus—and the onset of the attack is generally attributed to the same obvious cause as in ordinary cases; but there is, in addition, some history of exposure to foul drains or sewer gas odours. It is very probable that some other organisms obtain an effectual lodgment besides the pneumococcus under conditions favourable to cultivation. I am reminded of cases which I have seen in which the patient, whilst engaged in some unhealthy pursuit—for example, in the dissection of an animal far advanced in decomposition—has been exposed to severe chill—for example, by walking without an overcoat against a bitter wind at Brighton, the result being an acute pleurisy with purulent effusion. Similarly, a rheumatic endocarditis, by exposure to drain emanations, is very apt to become an ulcerative endocarditis.

12. It must not be omitted in the etiology of pneumonia to observe that certain diseases favour its occurrence—that is, are concerned in its etiology; tuberculous predisposition favours susceptibility to pneumonia; pneumonia occurs frequently

⁴ Netter, 1889, 70 cases, mostly complicated with other inflammations of a septic kind.

⁵ Weichselbaum, 1888, 29 cases quoted.

⁶ Levy, Seifrieder, Netter, 1890, 11 cases.

⁷ Professor Osler's experience (Pneumoniae Lectures, BRITISH MEDICAL JOURNAL, 1888, vol. 1, p. 380) would seem to be quite exceptional, namely, of his post-mortem observations at the Montreal General Hospital, 16 cases of acute endocarditis, of which 11 were ulcerative. I cannot myself recall a single case of ulcerative endocarditis as originating in pneumonia. There must have been some peculiarity in the sanitary surroundings of the cases of Osler to account for the prevalence of ulcerative endocarditis amongst them rather than the presence of the pneumoniae microbe, and it is to be noted that in 5 of the 11 cases purulent meningitis was also present.

⁸ Bacteriological inquiry by Klein, supplementary to Dr. Ballard's Report on the Pneumonia Epidemic at Middlesbrough, Medical Officers' Reports, 1888.

amongst the precursory diseases of the phthisical; influenza is still more directly a predisposing cause.

Influenzal pneumonia is commonly regarded as an inflammatory neuritis, and there is very much in its clinical characteristics to justify this view; nevertheless, the pneumococcus is as rampant a concomitant of influenzal as of other pneumonias, and there can be no doubt that the two poisons are at work in congenial co-operation.

13. Infection as a cause of pneumonia, as in tuberculosis, is a possibility, and some striking instances are forthcoming in regard to both diseases, but, nevertheless, when the etiological conditions common to members of the same family, or closely associated persons, are duly recognised and accounted for, but small need remains for direct infection in the etiology of the disease.

I have no personal knowledge of such, although as a matter of logical inference there can be little doubt of the possibility of its occurrence; but when we consider the small number of cases in which the question of infection arises; and bear in mind that epidemic influence (which may be a subtle change in atmospheric or other conditions favourable to the aggressive germination of micro-organisms which seem to be always more or less at hand) accounts for those cases amongst them in which the disease clusters in large groups; and that the apparently contagious spread in households is often accounted for by sewer-gas emanations common to the inmates; and further that such predisposing diseases as influenza are highly epidemic, there remains in truth not much etiological ground left for the contagionists to occupy.

PATHOLOGY.

I do not propose to touch upon the minute pathology of pneumonia further than I have been obliged incidentally to do in discussing the etiology of the disease.

TREATMENT.

In discussing the treatment of pneumonia, my time being very short, I shall not deal *seriatim* with drugs or methods, but shall discuss a few of the essential points only, points, however, which appear to me to dominate the whole line of treatment of the disease.

Attendant upon the pyrexial state pneumonia has, in common with other acute inflammatory fevers, certain conditions—as dry skin, loaded excreta, coated tongue, disordered intestinal secretions, and tension of pulse—which justify and call for what may be termed the routine treatment of pneumonia of the present day, namely, the saline treatment and the administration of occasional mercurial laxatives, and a liquid (unstimulating) dietary, with complete rest in an airy room, at a temperature of above 60° F., with a proper degree of moisture.

With regard to this treatment I have only two or three remarks to make:

1. It has a distinct value in materially depleting the vascular system from the venous side by means of increased functions of skin, kidneys, and bowels.
2. It is unnecessary and therefore harmful, to give the routine mixture oftener than four times in the twenty-four hours, leaving the intervening periods free, if necessary, for the administration of more concentrated remedies for special indications.
3. Indifferent doses of quinine or salicine may be given with the mixture to fulfil indications as regards general tone, rheumatic symptoms, etc.
4. In pathogenic cases the routine saline treatment would be replaced by quinine or salicine, in effervescence or otherwise, and in doses amounting to 20 or 30 grains of quinine, or 60 grains salicine in 24 hours.
5. My own observations, taking me back to a time twenty-five years ago, when, bleeding having been abandoned, antimony was still employed in pneumonia, and to more recent times when aconite was much in favour, impress me with the belief that both drugs are to be condemned for routine treatment, and that in uncomplicated cases of pneumonia the saline is the best routine treatment, and in the majority of cases the only treatment that is necessary to promote the favourable issue expected. Drugs of the aconite and antimony type often the pulse, and cause the skin to act by directly depressing the heart's action. I would give a

distinct preference for the citrates of ammonia and potash with some excess of ammonia if necessary, rather than the acetates, inasmuch as the latter seem to me, when given in considerable doses, to irritate the pulmonary and bronchial membrane, and to increase cough. In cases of distinctly low type, such as apex pneumonias of adults (apex pneumonia in children counts for nothing) and in drunkards free doses of tincture of perchloride of iron may be usefully given with the saline.

Pyrexia.—With regard to the fever of pneumonia, I would observe that it is a brief fever, lasting from five to ten days, that up to 104° F. it is symptomatic of, and normal to, the disease, those cases being, as a rule, most favourable in which it is most marked. If we accept, and we can little doubt, the view that pyrexia is a result of microbic activity, and admit (Table V) that that microbic activity commences and is most active at the lower ranges of the human temperature, and is inhibited at the higher ranges; secondly, as was so acutely suggested by Sir W. Broadbent in his address, that the products of microbic action, accumulating like those of the yeast ferment, tend in time to check further fermentation; thirdly, that the increased leucocytosis of fever is a provision for the phagocytic removal of torpid or inert coccus elements (see Table VI), we perceive the unwisdom of materially reducing the temperature normal to pneumonia, and that to do so by remedies which do not lend themselves to restrain microbic activity is distinctly harmful.

Cantani⁹ observes that "fever is the general reaction of the organism against the disease; it is a reaction phenomenon, the measure of the intensity of the infection on one side and of the power of reaction of the body on the other. Fever can be of use to the patient by injuring the vitality, multiplication, and perhaps also the virulence, of the living disease-producer in the body, through the high temperature of the blood and tissues; by raising the resisting power of the tissue elements in their phagocytic importance. Further, the tissue changes resulting from the fever can so change the food for many microbes that their virulence is lessened, their further multiplication in the body made impossible; they are biologically sterilised, and chemically their ptomaine production made innocuous."

With regard to antipyretics, he contrasts the action of quinine in malaria with antipyretics such as antipyrin, etc., in febrile processes, and points out that in all such affections it is a remedy like quinine that we want to discover which will affect the cause of the fever just as quinine reduces the fever of malaria by influencing the cause. Remedies like antipyrin, etc., cut short the fever by increasing the giving off of heat from the body, or by diminishing the heat production, and this can only do harm in that the cause of the fever is in no way affected, but the reaction weapon of the organism weakened.

In cases, then, of pneumonia, with what may be regarded, as the temperature normal to the disease, ranging between 103° and 104°, no special antipyretic measures are indicated unless such symptoms as delirium, restlessness, brown tongue, should indicate that the patient's nervous system is peculiarly sensitive to pyrexial conditions, in which case 5-grain doses of quinine and tepid sponging, especially with the addition of some stimulating evaporant such as eau de cologne, will reduce the temperature within the degree of comfort, that is, to between 102° and 103°.

When the temperature ranges above 104° it is *per se* an element of danger, tending, in addition to the unusual severity of the disease which it indicates, to damage the viability of tissue and to paralyse innervation, and most importantly that of the pneumogastric which controls heart and respiratory action.

In distinct hyperpyrexia the cold bath, the cold pack, or cold slucings, and the cold cradle¹⁰ are the only measures of any use, large doses of quinine aiding to maintain the reduction of temperature, but the bath should be very short,

⁹ Transactions of the International Medical Congress of Berlin, 1890. Compare also ROY, BRITISH MEDICAL JOURNAL 1893, vol. ii, p. 312. ¹⁰ Used both at the London and Middlesex Hospitals with distinct advantage in maintaining a moderate temperature.

TABLE VII.—*Elements of Danger in Pneumonia.*

Symptomatic.	Pathological.	Effects.	Treatment.
High fever, above 104°	Microbic activity Exhausted nerve centres	Shock	Bathing; quinine. Morphine preceded by accumulative stimulants and food. Leeches; ice applications.
Pain	(1) Over distension of capsule of lung from exudation and hyperemic swelling (2) Pleurisy	Sleeplessness Nervous exhaustion	— —
Rapid pulse (120) and breathing (40)	(1) Impaired pneumogastric innervation (2) Impaired nutrition of heart from insufficient and badly-aerated blood supply (3) Over distended right cavities Depleted left cavities	Cardiac failure	Blister-hot poultices (except very young and very old persons). strychnine, caffeine, atropine. Oxygen inhalations (earlier employment).
Extending physical signs	Extending exudation	— — —	Stimulants. Digitals and strychnine; blood letting, local or general, portal depletion. Acid tonics, perchloride of iron, after fifth day; oxygen inhalations (later employment).

N.B.—The above table is designed to show in brief the elements of danger in severe cases of pneumonia, and to indicate the lines of action to meet or anticipate them.

probably at most ten minutes, so that the temperature be not reduced below 102°. On this account the pack and cold slushing are more manageable than the bath for adults.

Too much must not be expected from this treatment of hyperpyrexia, as such temperatures as 106° are of themselves often of fatal augury on other grounds. In children the temperature can be easily held in sufficient control by frequent use of a bath at from 90° to 100°, and cold affusion to the head and neck, if necessary.

I have frequently observed that in small doses—2½ to 5 grains—in combination with quinine, antipyretics of the phenacetin class will usefully help to lower the temperature by a degree or so, and increase the action of the skin without depressing the patient. Pure willow salicin sometimes has a better effect than quinine.

The treatment of pain brings forward the still vexed question as to the use of poultices, and whether they should be hot or ice cold. Fully admitting the difficulty of weighing evidence, when the conditions of the problem are naturally so varied as those of pneumonia, I cannot say that I have any evidence that either hot or ice applications have any influence upon either the intensity, extension, or resolution of pneumonia.

The treatment of pneumonia by ice applications, which has been so strenuously and ably advocated by Dr. Lees, and has been advocated with more or less enthusiasm by many other physicians, is still a vexed question.

An inquiry made at all the great London hospitals, which has been most courteously responded to by the registrars, to whom my best thanks are due, elicits the fact that icebags are not largely used; that no special benefit upon the pneumonia has followed their use, their employment having been chiefly for the relief of pain and to lower pyrexia.

It seems, if I may venture to say so, that the icebag treatment of pneumonia has at once suffered and profited by its strenuous and perhaps too enthusiastic advocacy, and that what reputation it has gained has been more in the treatment of pneumonia of children than in adults, and its efficacy must therefore be rather gauged by the average mortality of children from pneumonia.

The tendency is in hospital practice, and is becoming so in private practice, to discard local applications in pneumonia, except for special reasons; and one strong argument in favour of their disuse is that their application involves more or less restraint and fatigue of the respiratory movements by the wrappings necessary to keep them in place. This especially applies to moist applications. Practical experience seems to go with theoretical knowledge in refusing any notable effect of ice applications upon the course of pneumonia; and my own prejudice is against them in ordinary cases, on the ground that I have observed increased inflammatory lung infiltration follow their use for hemoptysis, and that they are harmful in bronchitis. The following points are, however, distinctly in favour of their use in certain cases—namely, in cases in which there is great local discomfort with restlessness and a high temperature:

1. In the presence of high temperature they produce no

harmful effects, whilst they have the good effect in many cases of reducing the temperature some one to two degrees.

2. In the presence of pain, especially of the less acute kind, presumably due to general tumidity of a lung stretching its capsule, they give comfort and relief.

3. The icebag of Lees can be applied without impeding chest movements.

The pain of pneumonia is due to one of two causes, either the overdistension of the capsule of the lung from excessive swelling of the organ analogous to the pain of hepatitis, or pleurisy analogous to perihepatitis. Icebags will relieve the first of them. I should myself, however, generally prefer the free application of leeches.

The second is, in my experience, best relieved by the application of a blister for six or eight hours, with five or six hot linseed poultices applied over it in quick succession, so as to make it rise quickly and fully. In children, however, care should be taken with the use of blisters, and poultices alone, or the icebag should replace them. Leeches are sometimes valuable, and a small subcutaneous injection of morphine may be used to relieve the immediate suffering after the cause has been allayed by the local remedy.

The nerve shock and agitation of the early hours of pneumonia bears a very close relationship to the pain present, and to the rapidity with which the respiratory surface is being cut off by the extending exudation, in both respects being closely analogous to the effect of extensive pleurisy and rapid effusion.

To meet both the indications the addition of small doses of morphine to the routine mixture is very valuable in sustaining the patient during the first forty-eight hours. After this time the use of morphine requires the most careful consideration; on the one hand, it tends to check secretions and to increase cyanosis, and to enervate the patient in the struggle that is before him; on the other hand, in the overwrought nervous systems with which we have often to deal, intolerant of suffering or discomfort, disturbed and fretted by thoughts and surroundings, exhausted by want of sleep, the skillful use of morphine is of the greatest value.

In the presence of active delirium, with prolonged sleeplessness, I am convinced that the proper treatment is a full or rapidly accumulating dose of alcohol with food, followed at the right moment by a sufficient dose of morphine with atropine subcutaneously. If cyanosis be a marked feature, and if there be a tendency to break out into sweating (an almost invariable accompaniment of cyanosis) oxygen must be administered freely whilst the patient is under the narcotic.

Coming now to cardiac failure, there seem to me to be three conditions which we have especially to bear in mind as leading up to it:

1. Impaired nerve power on the part of the pneumogastric branches of the cardiac plexus.
2. Impaired nutrition of the hard-working heart muscle from insufficient and badly aerated blood supply.
3. A mechanical tendency to over-distension of the right heart cavities, and to depletion of the left cavities of blood.

With these three factors contributing to heart failure clearly before us, and with clinical evidences of rapid compressibility, smallness, and vacillation of the pulse and of enlarging and labouring right ventricle indicating them, we have at hand remedies of great power to do what may be done in any given case.

I have spoken of morphine with atropine as, cautiously and properly used, being very valuable in saving from nervous and cardiac exhaustion. The addition of atropine would be especially suitable in the later periods of pneumonia.

Strychnine and caffeine are, however, the two drugs which are of the highest value in maintaining the innervation of the heart in many cases of pneumonia; perhaps in all cases of any severity, a moderate dose of 2 to 5 minims of liquor strychninae may be given four or six times in the day from the fourth to the fifth day onwards through the crisis.

Let me here point out that it is perhaps best in all cases, but most important when carbonate of ammonia or any other alkali is being given, to place the strychnine in a separate bottle, and either mix it with the dose of saline at the time of taking, or give it separately with the stimulant or food at some separate time, since the strychnine, thrown down in the presence of an alkaline carbonate, tends to accumulate at the bottom of the bottle.

In very severe cases of pneumonia, too, the stomach sometimes becomes paralysed and acutely dilated, and ceases to absorb, so that no immediate effect, but considerable ultimate danger, would result from introducing dose after dose of strychnine under such circumstances. In all severe cases it is indeed safest and best to administer such drugs subcutaneously.

The effect of strychnine in increasing power and lessening frequency of heart's action is undoubted. I have used caffeine much less; it appears to me to have the same effect as strychnine, being perhaps on the one hand less reliable, and on the other, there being less danger from an incautious dose.

The value of oxygen in the treatment of pneumonia has, I think, been somewhat misinterpreted. It is twofold: (1) No doubt, in the first place, it will help to keep the patient alive in a small respiratory surface, which would otherwise be inadequate for that purpose, and a very few cases may thus be saved. (2) But the second action of oxygen is a more important one, and applies to many diseases besides pneumonia—namely, the direct effect of its inhalation upon the heart by sending more richly oxygenated blood to its left cavities and to its muscular walls.

The general practice of the London hospitals is only to use oxygen in desperate cases for the treatment of cyanosis, with the effect of maintaining life a little longer, but with no other good result. I would venture to urge its use also, and indeed, rather as a cardiac tonic, to anticipate, and if possible avert, heart failure by helping cardiac nutrition. Oxygen also lessens that restlessness which is attendant upon defective aeration and hurried breathing. Its effect is to lower the pulse-rate and to diminish the number of respirations.

Overloading of the right ventricle and depletion of the left is the cause of death in many cases of pneumonia. The right ventricle becomes overtaxed from obstruction to circulation through the lungs in consequence of excessive exudation. With its increasing distension and failing power to empty itself during systole, engorgement of the whole venous circulation increases, whilst the left cavities of the heart become starved of blood. In a few plethoric people this may come on acutely in the very early stage of the illness, but we more often see it in the later period, its occurrence being characterised by increasing epigastric pulsation, and smallness and emptiness, with increasing rapidity, of the radial pulse. The question of blood letting in pneumonia is rarely raised now, but these are the two conditions which warrant its use, either by the free application of leeches or a moderate venesection. I have only myself hitherto used venesection in acute distension of the heart with bronchitis and pulmonary engorgement, but I have seen very marked benefit, even from the free application of leeches in pneumonia, and in some cases a moderate blood letting is certainly indicated. These are the cases also in which digitalis becomes valuable in addition to strychnine; and I am confident that I have seen this danger warded off by its timely use, although digitalis has little effect in diminishing pulse frequency in pneu-

monia. A dry diet and the judicious use of mercurial and saline purgatives help further to lessen the burden on the right ventricle.

Can we do nothing to check the extension of exudation and oedema of the working lung? It has seemed to me important in this regard to throw aside the saline treatment at about the fifth day of the disease. Carbonate of ammonia, valuable at a pinch for two or three days, loses its useful effect and appears to me to impair the blood condition after that time; at least I have often observed benefit arise from replacing it by dilute phosphoric acid or other mineral and bark and strychnine. The late Sir Andrew Clark had, during the last few years, come to the opinion that perchloride of iron was of value in checking excessive exudation. I am much inclined to the same view, and have long been convinced of its value in adynamic cases.

These cases raise again the question of the value of ice applications in checking the local extension of pneumonia. Dr. Lees eloquently and confidently advocates their use, and points out that increased resonance and subcrepitant râles may be heard over the part to which the ice is applied, whilst the fever temperature is maintained, showing the general disease to be active whilst its local effects are restrained and reduced by the application. I cannot accept this argument as at all conclusive, for it is a very common experience, if it be not universal, to observe that *radix crepitation* generally appears after the fourth or fifth day of consolidation over a given area of lung quite apart from the activity of the disease, which may be manifesting itself by extending consolidation above or in the other lung.

My task now draws near its close, for I wish to limit this discussion to pneumonia, and time does not permit me to touch upon other than its immediate complications.

It will be asked, What about the microbes and their treatment? And one of the very kindly critics of my work on *Diseases of the Lungs* rather severely fell upon me for not speaking at greater length and with greater emphasis upon the subcutaneous antitoxin treatment of pneumonia advocated by Klempner. But, Sir, that book was designed as a practical work, and I cannot say that even yet the antitoxin treatment of pneumonia has come within the range of practical medicine. It is adopted in no London hospital, and we are not even yet quite sure of our microbes, nor do we know that we have yet a safe antitoxin.

My colleague, Dr. Coupland, the other day had a desperate case of pneumonia in his ward, whilst I had a severe case which had just reached the crisis. I thought it right to raise a blister in my case with a view to injecting some of the serum into his, but before the blister rose my patient had a severe relapse, so that the treatment did not come off.

The practical difficulties of carrying into effect antitoxin treatment of pneumonia are great. It is difficult to find a convalescent patient ready and willing to supply the blood. The period of immunity is of very short duration, so that even immunised serum from animals will be difficult to obtain in constant and efficient supply.

I cannot say that I should feel justified in any but a desperate case, with our present imperfect knowledge, in injecting a patient; and that is frankly how I find the case to stand at present. With such crude ideas as we have on this subject, it would be quite unjustifiable to let loose upon the medical public a method of treatment that is fraught with its own dangers. I am hopeful, however, that we may hear to-day some hint at least of progress on the lines that have proved valuable in some other acute specific diseases.

II.—J. W. WASHBURN, M.D., F.R.C.P.,

Physician to the London Fever Hospital; Assistant Physician to Guy's Hospital; Demonstrator of Bacteriology, etc.

In discussing the paper to which we have been listening, I will confine my remarks to the opinions I have derived from a fairly extensive experimental experience of the disease.

At the outset I will say that I look upon acute croupous pneumonia as a specific disease produced by the invasion of the lung with the pneumococcus of Talamon, Fraenkel, and Weichselbaum. The microscopical changes in the affected lung are those of a simple fibrinous inflammation possessing no specific character which distinguished it from an inflammation caused by other micro-organisms.

The formation of fibrin in the alveoli is in excess of that found in other inflammatory conditions of the lungs, but this is only a question of degree. The most characteristic point in the morbid anatomy of acute croupous pneumonia is the way in which the inflammation spreads so as to involve the whole of one or several lobes. Nevertheless, the inflammation may remain localised to a small portion of the lung, as in the so-called "deep-seated" pneumonias.

In broncho-pneumonia fresh portions of the lung become infected by the conveyance of micro-organisms from one bronchiole to another; but in croupous pneumonia contiguous portions of the lung become infected by the passage of the micro-organisms through the alveolar walls. It is this mode of invasion which distinguishes a lobar from a lobular pneumonia.

In spite of these distinctions we must consider the growth of the pneumococcus, and not the anatomical changes produced, as the essential factor in the disease. There appear to be rare cases of acute lobar pneumonia which are not caused by the pneumococcus, and which I would exclude from the category of acute croupous pneumonia. That such cases should occur is in accord with what we should expect from analogy with other diseases. For example, other micro-organisms than the diphtheria bacillus are capable of producing a membranous inflammation of the fauces, and other micro-organisms than the tubercle bacillus will produce chronic infective granulomata.

Should further experience confirm the occurrence of these non-pneumococcal pneumonias, I believe that careful clinical observation will enable us to distinguish them from the ordinary pneumococcal forms. As far as we can judge, they appear to be more infectious than ordinary pneumonias, as, for instance, in the Middlesbrough epidemic, investigated by Professor Klein.

I have never met with such infective pneumonias, and have never failed to demonstrate the presence of the pneumococcus in any of the many cases of acute croupous pneumonia I have examined *post mortem*.

The demonstration of the pneumococcus requires some care, for the micro-organism is not easy to cultivate, and in the later stages of the disease it dies out and is replaced by other micro-organisms which have secondarily invaded the lung. In the recently-affected parts the pneumococcus is present in large numbers and to the exclusion of other bacteria. The inoculation of animals is the most reliable method of demonstrating the pneumococcus.

Different animals vary in their susceptibility, the mouse and the rabbit being exceedingly susceptible; the guinea-pig is less susceptible, and the fowl quite immune.

Septicæmia is the usual result of inoculation, but under certain circumstances pneumonia is produced.

Intratracheal inoculation in dogs frequently causes pneumonia, and it is stated that inhalation with certain varieties of the pneumococcus invariably produces pneumonia in rabbits. Sometimes we meet with pneumonia in rabbits after subcutaneous or intraperitoneal inoculation, especially with attenuated cultivations.

The pathological changes produced in animals depend upon the susceptibility of the animal, the virulence of the pneumococcus, and the mode of infection. Subcutaneous inoculation in rabbits may produce no local reaction, or an oedematous, fibrinous, or purulent inflammation. After death the blood may be found crowded with or may be quite free from cocci. Recovery usually ensues when an abscess forms at the spot of inoculation. After intraperitoneal inoculation peritonitis is almost always observed. In some cases the animals die at a late period with marked emaciation, and no cocci can be found in the blood or organs.

Several varieties of the pneumococcus have been described differing from one another in the symptoms they produce in animals. The most marked of these varieties is the one met with in cases of meningitis. I believe that these varieties only differ from one another in virulence, and that by suitable means they can be converted into one type. It is, however, an important point to remember that the pneumococcus in the human subject does vary enormously in virulence, for it will partially explain the severity of the symptoms in different cases.

I have already stated that the pneumococcus may rarely

produce in the human subject a lobular and not a lobar pneumonia. But this by no means exhausts its rôle in human pathology. It may cause fibrinous pleurisy, empyema, meningitis, acute otitis media, peritonitis, ulcerative endocarditis, arthritis, and suppurative lesions in other parts of the body. These conditions may be primary or may be secondary to an attack of pneumonia. I believe that in all these cases the pneumococcus gives a peculiar type to the disease, but this may be masked by the local inflammation. When, for instance, the meninges of the brain are attacked, the usual toxic effects of the pneumococcus are overshadowed by the cerebral symptoms caused by the interference with the functions of the brain.

I am quite satisfied that when the pneumococcus invades the pleura, producing either a fibrinous pleurisy or an empyema, the constitutional symptoms are precisely similar to those of pneumonia. It is only by a careful physical examination that such cases can be distinguished, and even this may at times fail. I believe that many of the cases considered to be empyemata, following upon pneumonia, are really cases of primary empyemata, without any previous affection of the lung.

Now, the fact that the pneumococcus is found in so many diverse conditions has been urged as an argument against the view that it is the cause of pneumonia. I cannot consider this argument valid. It is a general law in pathology that the same micro-organism may produce a different train of symptoms according to the part attacked. The tubercle bacillus causes a different type of disease when it attacks the joints, lungs, peritoneum, or brain. I think we ought to speak of a pneumococcal otitis or a pneumococcal pleurisy just as we speak of a tuberculous otitis or a tuberculous pleurisy.

Although the pneumococcus is the cause of croupous pneumonia, yet for the disease to develop there must be other factors than the mere presence of the micro-organism. There must be some predisposing cause, for the pneumococcus is widely distributed, and is often present in the mouths of healthy individuals without producing any ill effects.

Under ordinary circumstances the protective mechanism of the body prevents invasion; but should the cocci be introduced in very large numbers, or should the natural resistance of the body be lowered, invasion occurs and the disease develops. In many cases both these factors operate. The introduction of a large number of germs perhaps determines the seasonal prevalence of the disease.

As to predisposing causes influenza is the one best known. It is quite common for patients convalescent from influenza to fall victims to a lobar pneumonia caused by the pneumococcus. The attack of influenza has so lowered the resistance of the body that it yields to the invasion by the pneumococcus. We must distinguish an acute lobar pneumonia occurring during convalescence from influenza from a pneumonic consolidation of the lungs occurring during the attack. The former is caused by the pneumococcus, and only differs from a primary attack of lobar pneumonia in increased severity; the latter is due to the influenza bacillus, and presents a different clinical aspect. Sometimes a pneumonia, caused by the pneumococcus, does occur during the acute stage of influenza, but this is uncommon. In scarlet fever we meet with an analogous condition. During convalescence from this disease patients are liable to be attacked with a membranous inflammation of the throat caused by the diphtheria bacillus, differing from ordinary diphtheria only in increased severity. During the acute stage of scarlet fever a membranous inflammation of the throat is common, but is not caused by the diphtheria bacillus. In rare cases, however, a true diphtheria complicates the acute stage of scarlet fever.

The other predisposing causes of pneumonia, such as cold and fatigue, are not capable of direct proof. Experimental evidence tells us that exposure to cold and fatigue renders animals susceptible to bacterial infections which in the normal condition they were able to resist. It is interesting to note in this connection that the growth of the pneumococcus outside the body is greatly influenced by very slight changes in the composition of the medium. By analogy we might suppose that slight changes in the composition of the body fluids would be favourable or unfavourable to the

growth of the cocci; but this analogy must not be strained, for it would be incorrect to compare too closely the conditions within the body with those occurring in test-tube experiments.

With regard to the manner in which the symptoms of pneumonia are produced, I have no doubt they are caused by the formation of toxins which act deleteriously on the various tissues of the body. The rapid breathing may in part be explained by the physical interference with respiration, but only in part, for with the crisis the respirations slow down, although the consolidation of the lung remains. When the lung is extensively involved the mechanical effect upon the respiration is of serious import. At the same time, with a larger area involved more toxins are produced and more danger arises from this cause.

Our knowledge of the toxins of the pneumococcus is still very defective. In artificial cultivations only feeble toxins are produced, and it is thus difficult to study their action carefully. There is, however, sufficient evidence to show that the toxins produce similar constitutional symptoms to those caused by infection with the pneumococcus.

Compared with such animals as the mouse or rabbit, the human subject must be looked upon as resistant to infection with the pneumococcus. As a rule the cocci remain localised to the lung, and are prevented by the natural resistance of the body from spreading to the other organs, and from multiplying in the blood. In fatal cases the cocci may be found in small numbers in the various organs.

The inflammatory changes in the lung are of a beneficial nature, having for an object the localisation and destruction of the cocci. The natural reaction of the body to the infection is shown by a leucocytosis of the blood. It would appear that when this occurs the case is favourable, but should it be absent a fatal termination is to be apprehended.

The crisis in pneumonia is of great interest. Often quite suddenly the temperature falls, and the constitutional symptoms subside. This is not due to a sudden destruction of the cocci; for living cocci can be demonstrated in the sputum for some time afterwards. There is good reason for supposing that it is due to the formation within the blood of a substance, perhaps improperly called an antitoxin, which protects the body against the injurious effects of the pneumococcus. Such a substance has been found in the blood of patients after the crisis. Injection of the blood serum of patients convalescent from pneumonia is capable of protecting animals against infection with the pneumococcus. My own experiments, as far as they go, confirm these results.

There are doubtless other factors concerned in recovery, such as phagocytosis and a destruction of the cocci by the fluids of the body. The question is of the greatest importance, for its solution will place us in a position to successfully treat the disease.

Various observers have shown that the blood serum of animals rendered artificially immune possesses the power of protecting other animals against infection, and of curing the disease in an early stage. My own experiments confirm this statement.

Attempts have been made to apply this principle to the treatment of pneumonia in the human subject, but at present only with partial success. The difficulty is to obtain a powerful serum in sufficient quantities. I believe this will only be a question of time, and that ultimately the same success will be attained in the treatment of pneumonia as has already been obtained in the treatment of diphtheria.

The last point I will touch upon is in reference to certain sequelae that possibly may follow upon an attack of pneumonia. In a few cases after inoculation of the pneumococcus in rabbits the animals have died at a late period without any living cocci being present in the body after death. In two cases I found a chronic parenchymatous nephritis. Now the observations of Fraenkel and Reiche have shown that epithelial changes are frequently to be found in the kidneys of the human being after death from pneumonia. In view of these facts I think it probable that some cases of chronic nephritis are due to an antecedent attack of pneumonia.

Still more interesting are the observations of Professor Welch, who has shown that after injection of the pneumococcus

or its toxins, necrotic foci frequently occur in the liver. Inflammatory changes take place around these foci and ultimately lead to the formation of fibrous tissue. Rarely a degeneration of the liver cells occurs. In a private communication Professor Welch informs me that he has found similar foci in the human liver after pneumonia. These observations are of great importance in connection with the etiology of cirrhosis of the liver. It is usual to attribute this disease to the abuse of alcohol, and no doubt this view is correct in the majority of cases. Nevertheless, cases do occur in which no connection with alcohol can be obtained. I think it quite likely that some of these cases may be due to an antecedent attack of pneumonia.

III.—A. G. AULD, M.D.,

Assistant Physician to the Royal Infirmary, Glasgow.

LIKE Dr. Douglas Powell and Dr. Washbourn, I regard the disease termed pneumonia as a specific fever, but a fever which has almost invariably a marked local manifestation in the lung. It is not necessary, in my opinion, that the lesion of this fever should be situated in the lungs, for it may be found in the meninges of the brain, and very possibly also in the peritoneum. With respect to the local process in the lung, it has been regarded by some, and in particular by the late Sir Andrew Clark, as not a real or genuine inflammation, but a spurious or abortive one.

Without entering into the arguments for this view, I may say that the processes of leucocytosis and phagocytosis which we find in pneumonia seem to me to warrant the view that the lung in pneumonia is really inflamed in accordance with the notion of inflammation which the great work of Metchnikoff has given us. Granting that the pneumococcus of Fraenkel is, in the great majority of cases, the cause of the disease, we have an abundant production of these cocci in the lungs, and in addition to this there is, no doubt, the elaboration of a toxin by these bacteria, which gains admission to the general mass of the blood. The result of the bacterial infection is the production of a leucocytosis, which is most marked at the height of the fever. The leucocytosis diminishes with the temperature, and in cases terminating by lysis the leucocytosis likewise displays correspondingly gradual declension. In regard to the local lesion, we have an exudation which differs considerably in different cases. These varieties indicate the degree of virulence of the inflammation. When the exudation is chiefly fibrinous, we have usually rapid resolution, but when there is much effusion of leucocytes, there is a condition of greater gravity. The severity of the disease, and this is usually found in debilitated constitutions, calls forth this marked emigration of leucocytes, which, though a bad sign as far as the patient is concerned, is, nevertheless, a good thing in itself, and must be regarded as a defensive process. Just as the fever is a constitutional means of defence, so the corporeal exudation is a local means of defence. The occurrence of consolidation I regard as a salutary event, for by it we have the imprisonment of an enormous number of microbes whose powers for evils are thus checked. Now what occurred at the crisis? I believe we have in this the production of an antitoxin in the blood which directly meets the toxin. This is also usually the signal for a change in the consolidated condition of the lung, but this is not always so. Sometimes the consolidation remains, at least for a time, and this is an important point in connection with the pathology of the disease, which, however, I cannot enter into. Dr. Douglas Powell has indicated a doubt whether we can ascribe pneumonia to any one microbe in opposition to the opinion expressed by Dr. Washbourn. It seems to me that Dr. Powell's contention cannot afford to be set aside, and further investigation is required. I may mention that in a case of acute pleurisy with slight pneumonia, I injected some sputum into a rabbit with the result that an intense membranous pleurisy resulted. Now in this case the pneumococcus was found and was supposed to be the cause of the disease, yet how was it that the organism when injected preferred to attack the pleura? There must have been some attraction to the pleura which was not fully explained by the theory which Dr. Washbourn has propounded, or else there must have been a different organism.

IV.—J. DARSCHFELD, M.D., F.R.C.P.,

Professor of Medicine in the Victoria University, and Physician to the Manchester Royal Infirmary.

Few pathologists doubt that Fraenkel's diplococcus is the exciting cause of croupous pneumonia, but other micro-organisms may give rise to an inflammatory infection of the lung which produces symptoms like those of croupous pneumonia. Thus Friedländer's bacillus was found in some cases of wandering pneumonia. Several members of the same family were affected, and the naked-eye and microscopic investigation discovered appearances of croupous or lobar pneumonia. I want to draw attention to influenza pneumonia (1) which at the time of an epidemic croupous pneumonia, due to Fraenkel's coccus, is usually very prevalent; (2) patients with influenza are very much predisposed to take croupous or lobar pneumonia; and (3) there is a pneumonia due to the influenza bacillus, and which pathologically is in most cases, but not in all, lobular or pseudo-lobar pneumonia. Clinically we have here various types—a wandering pneumonia is the commonest type, apex pneumonia is another type, and central pneumonia with few physical signs (slight dulness, distant bronchial breathing, a few crepitations) is a third type. A common feature of these types is that there is a more or less remittent pyrexia, that the disease ends in lysis and not in crisis, and that the sputum is purulent but not rusty. Microscopic examination of the sputum shows, as has first been demonstrated by Pfeiffer, masses of very small and slender bacilli—the influenza bacilli. Influenza pneumonia is highly infective, and is often complicated with empyema, which however, as a rule, subsides without surgical interference. Occasionally acute influenza pneumonia leads to a subacute form, with the physical signs and general symptoms of acute tuberculous phthisis. The examination of the sputum assists us in the true recognition of this form, the prognosis of which is fairly good, recovery frequently occurring after an illness of several months' duration.

V.—J. E. POLLOCK, M.D., F.R.C.P.,

Consulting Physician to the Hospital for Consumption, Brompton.

I WOULD more gladly add some fragment of additional knowledge to this discussion rather than criticise modern views from the standpoint of clinical experience, but I feel that all modern experiment from the laboratory must be brought down to the level of clinical experience to become practical. We cannot but admire the elaborate researches which have brought to our knowledge the fact that many diseases are found to be connected with microbes peculiar to them. These facts are undeniable, and secured to us by evidence, but the deductions from them which are now so universally received are themselves subject to the errors of evidence. These deductions as advocated are (1) that the microbe found in the organ locally affected is the cause and not the consequence of the disease. (2) That such disease is communicable by inoculation, and even by contact of the healthy with the diseased person, and from this results the therapeutic necessity for isolation of such persons. (3) That the disease can only be generated by such means, that is, contact or inoculation. (4) As all persons so exposed do not get the disease, it is necessary to argue that there is a previous receptivity in certain individuals, receptivity due to heredity or general weakness lowering resisting power. The evidence obtained in the laboratory must be received subject to the test of clinical experience. Regarding the direct causation of pneumonia, in the vast majority of cases it is due to chill, as, for instance, in a case of death on the fourth day from double pneumonia in a person previously in robust health, and with no antecedents of disease, personal or hereditary. Such cases are within the experience of all of us, and occur without the possibility of contagion. Further, the evil social consequences of the contagious theory as regards tubercle and pneumonia, the subjects of which are according to it to be marked "dangerous," and deprived of the attention of wife, or husband, or parent. Finally, while acknowledging the great and important discoveries of the laboratory, I would still plead for the necessity of such conclusions being tested by clinical experience.

VI.—A. FOXWELL, M.D., F.R.C.P.,

Physician to the Queen's Hospital, Birmingham.

NINE years ago, in a paper in the *Practitioner*, I endeavoured to show that this was a specific constitutional disorder. My reasons were briefly three (1) Nearly always other portions of the body are involved in the disease. Generally these are certainly of subsidiary importance but not invariably. Sometimes the other tissues bear the brunt of the attack; for example, a case is diagnosed as one of acute peritonitis, but later pneumonia is discovered and our nomenclature is altered. (2) The inflammation of the lung is of very various anatomical form. (3) There may be no lung inflammation, and yet all the clinical symptoms of "pneumonia" are present. (4) The *Symptom-complex* of the disease remains one and the same through all these vicissitudes. Like tubercle, so may "pneumonia" not always be constitutional. We may have a purely local inflammation of the lung without pyrexia or other constitutional symptoms, just as we may have tuberculosis of the cervical glands; so, too, I believe pneumonia is sometimes represented by a local inflammation which does not involve the lung, for example simple acute meningitis, pleurisy, or peritonitis. Our routine treatment at the Queen's Hospital, Birmingham, for failing heart is the subcutaneous injection of strychnine in doses of $\frac{1}{4}$, or 5 minims given every eight, six, or four hours. Packing with ice-cold water I consider most valuable in all cases of restlessness and insomnia in children; it is also the best method in my opinion for the reduction of excessive temperature.

VII.—W. J. TYSON, M.D., M.R.C.P.,

Folkestone.

IT WOULD be difficult to say anything new in connection with the everyday subject of pneumonia, and our task has been rendered even more difficult by the admirable, full, and lucid description which we have just heard. I wish to say a few words in respect to the classification of pneumonia. It seems to me that before long the word pneumonia must be accompanied with a foregoing adjective stating what form of the disease we are dealing with. There are so many types of pneumonia, widely differing from one another, which are now classed under the common term of pneumonia: for instance, there is alcoholic pneumonia, influenza pneumonia, septic pneumonia, symptomatic pneumonia, and many others, differing from one another anatomically, pathologically, and therapeutically, yet all are more or less classed under the head of pneumonia. The words meningitis and peritonitis are almost anachronisms without adjectives stating the course of the meningitis and peritonitis, for without the qualifying word the disease is not diagnosed, and therefore cannot be treated. I have no doubt that in time our friends, studying the laboratory aspect of pneumonia, will be able to explain more fully than they have yet done the various clinical types which we who are in the active practice of clinical medicine are in the habit of meeting with, recognising, and treating according to type.

VIII.—GEO. W. BALFOUR, M.D., LL.D.,

Consulting Physician to the Edinburgh Royal Infirmary.

MR. CHAIRMAN AND GENTLEMEN,—The history of medicine teaches us that there is probably no disease which has been claimed to be cured by so many divers forms of treatment as pneumonia. Cullen, Gregory, and their followers imagined that they could cure this disease with large bloodlettings, and that this was the only rational treatment; Ross and Laennec supposed they had been equally successful with contra-stimulant doses of tartar emetic; while Hahnemann and Fleischmann with infinitesimal doses of phosphorus, and Bennett with his restorative system, claimed to have almost annihilated the mortality of pneumonia. And Kiska with his extractum graminis, and Dietl with his aqua colorata were not so presuming, they at least plumed themselves on being quite as successful as their competitors. Even in our more modern days the case is not different, for we can scarcely take up a medical periodical in which some one does not proclaim the discovery of some new specific for the treatment of pneumonia. And yet the mortality from pneumonia bulks as largely as hitherto. The success claimed to be

attained by treatments so various, and so antagonistic in their mode of action, seems to indicate that in pneumonia treatment has but little influence in promoting recovery. It may be that in the near future the discovery of a new antitoxin may place in our hands a specific for the cure of pneumonia, but at present we must be content to relieve suffering and to obviate the tendency to death.

Death in pneumonia, whether it arises from sudden syncope, pulmonary oedema, or gradual sinking, is invariably connected with cardiac failure as its beginning and its end, and whatever impairs cardiac energy increases the danger to life.¹ Hence advanced age, pre-existing disease, or preceding bodily or mental exhaustion, however induced, are all serious complications, and if we delete from the death-roll of pneumonia all those cases in which one or other of those conditions has been present, we practically eliminate all the fatal cases. Unfortunately we have no treatment that can nullify the ill-effects of age, of pre-existing disease, or of exhaustion, but at least we can avoid any treatment likely to produce or increase any of these ill-effects. Indeed, there is a pretty general consensus of medical opinion that when any of the conditions mentioned are present, depressing or perturbative treatment is specially to be avoided. But if depressing and perturbative treatment is to be shunned when elements of danger already predominate, it is difficult to see why they should ever be employed, as in themselves they are fraught with menace to the cardiac energy.

There are two circumstances liable to happen in the course of a pneumonia which are supposed to be specially detrimental to the heart; the one is excessive consolidation of the lung, and the other an excessive rise of temperature. Excessive exudation in any situation impoverishes the blood and enfeebles the vigour of the heart, but in this respect it is not more injurious within the pulmonary tissue than it would be anywhere else, while as a possible cause of strain to the right heart it is of small moment, as the instant the temperature falls convalescence proceeds uninterruptedly, the heart making no account of the apparent obstacle. This, moreover, is a matter over which treatment has but little influence, as limitation of the exudation depends upon arrest of the disease, and as yet we possess no certain means of attaining this result.

A high temperature undoubtedly exhausts nervous energy and enfeebles muscular power, and must therefore impair cardiac vigour; but the pyrexia in pneumonia is usually moderate, and an exceptional or dangerously high temperature may be accepted as an indication of some serious and probably fatal complication. Antipyretic treatment is, therefore, much less applicable to the treatment of pneumonia than to that of other diseases, where the local lesion is of less ominous import.² Moreover, powerful antipyretics possess a distinct danger of their own, which is probably not less than that they are employed to avert.

There is, however, one antipyretic, formerly much used as an antiphlogistic, as the equivalent of blood-letting,³ which skillfully used has distinct advantages of its own. It is true that when the full antipyretic action of digitalis happens to coincide with the natural crisis of a pneumonia, the rapid and often considerable fall of temperature, sometimes amounting to four or more degrees within a few hours, occasionally gives rise to some anxiety, an anxiety apt to be accentuated by the coexistence of a feeble and irregular pulse. This feeble irregular pulse has been accepted as an indication that digitalis enfeebles the heart, and ought to be shunned in the treatment of pneumonia, or only employed exceptionally when the heart is strong and vigorous, but the case is quite otherwise; the feeble and irregular pulse of critical or precritical cardiac collapse, that occasionally occurs when no digitalis has been given, is best treated by free stimulation along with large doses of digitalis, and I have occasionally employed with success as much as a whole drachm of the tincture of digitalis every hour or every two hours, and repeated from six to twelve times. The feeble and irregular pulse accompanying a pneumonic crisis where digitalis has been freely employed is quite another story;

it is not an indication of cardiac debility but of digitalis poisoning, such as might happen under any circumstances when digitalis has been equally freely employed. This condition is alarming and not free from danger; when it accompanies pneumonia the recumbent posture must be strictly enforced and stimulants administered. We gather from Withering⁴ that the presence of inflammation inhibits the action of digitalis, so that very large doses indeed are required to lower the pulse or depress the temperature in pneumonia, as much as from 100 to 120 grains being often required for this purpose. Even when such large doses of digitalis have proved successful in lowering the temperature the disease is not always arrested, and the rusty sputa may continue for some days along with a slow pulse and a low temperature.⁵ There seems, therefore, some risk to be run, and no certainty of any important gain, from pushing digitalis in this extreme manner. On the other hand, if we use this drug in moderation throughout the disease, we gain two advantages: in the first place, the antipyretic virtues of the drug probably aid in bringing about an early crisis, and in making it more complete; and in the second place, the tonic action of digitalis on the heart enables us to keep that organ well in hand; this may in some cases avert cardiac collapse, it certainly enables us to rouse a failing heart with less loss of time than when digitalis had not been given from the commencement.

In order to secure all the advantages obtainable from the use of digitalis, without any of its disadvantages, I am in the habit of prescribing half an ounce of the ordinary infusion of the *Pharmacopoeia*, to be given every four hours till the crisis occurs. Afterwards this drug is either stopped, or given for a short time at longer intervals, appropriate tonics being subsequently substituted.

Apart from those conditions already referred to as likely to determine the early occurrence of general and specially of cardiac exhaustion, there are several accessories of the disease which have a similar tendency, and which must be combated if we desire to conduct our patient safely and comfortably through his illness. These accessories are sleeplessness, pain, and cough; the two latter are often a cause of the insomnia; but sleeplessness itself is frequently only a symptom of nervous exhaustion; or it may initiate this condition, as it will most certainly aggravate it. Opium has long been employed for the relief of these symptoms, but certain untoward effects, apt to follow its use have prevented opium being so much trusted in pneumonia as it is in some other inflammatory affections. Many years ago the inhalation of chloroform was employed by some German physicians in the treatment of pneumonia with very considerable success, a success that was all the more remarkable from having been pretty equally distributed amongst all the physicians concerned.⁶ Under this treatment pain vanished; insomnia was replaced by a childlike slumber; the cough ceased, and the rusty glutinous expectoration was speedily changed to a scanty mucous phlegm; the temperature dropped, the pulse-rate fell, and the patient speedily convalesced. But the employment of chloroform by inhalation was wasteful, troublesome to manage, and not devoid of danger, some of the few deaths that occurred having been credited to the treatment rather than to the disease. The difficulties, dangers, and expense attendant on giving chloroform by inhalation were greatly overcome by giving it by the mouth, one drachm so given producing safely results only to be attained at some risk by the inhalation of an ounce.⁷ The giving of chloroform by the mouth in such cases had only one drawback: it did not relieve pain so quickly as when it was inhaled. In every other respect it acted quite as beneficially. Probably the relief of pain was only a question of dose, but this matter did not require to be further investigated, as just at this time Liebreich's fortunate discovery of chloral presented us with a drug which seems to possess all the advantages of chloroform, coupled with greater facility of administration.

In lethal doses chloral causes a fatal depression of temperature; it is therefore an antipyretic. Chloral slows the heart, and dilates the arterioles. It is an excellent hypnotic; it is

¹ The danger in pneumonia is pneumonia threatens principally the heart of the patient. Death results from insufficiency of the heart."—Jervenson, *Elements of Medicine*, vol. v, p. 100.

⁶ *Lancet*, 1849, April 10th, p. 408.

⁷ *Lancet*, loc. cit.

also an analgesic, and it diminishes and ultimately abolishes all the reflexes. It would be difficult to find another drug with so many virtues likely to be useful in the treatment of pneumonia, and withal so manageable in its administration. It is not strange that it has been found extremely serviceable.

If we hold to the old-fashioned view that pneumonia is a reaction to an injury received, then by its action on the reflexes chloral must modify this reaction, checking wholly or in part the series of organic changes through which unmodified diseased action must run. This action is specially valuable in those exhausted and irritable constitutions in which reaction is apt to be both excessive and dangerous. In this theory of inflammation dilatation of the arterioles is not without its use; the free circulation sweeps away in its torrent all the stasic elements, and the influence of the morbid stimulus gradually dies away as the normal nutrition of the part becomes fully restored.

On the other hand, if we regard pneumonia as due to the action of a coccus, a bacillus, or any other form of microbe, the flushing of the part affected by a free circulation of healthy blood cannot be a matter of indifference, as by flooding the part with phagocytes it must tend to cut short the disease by destroying its cause.

Whether, therefore, we hold old or new views as to the causation of pneumonia, the treatment of it with chloral would seem to be perfectly appropriate from a physician's point of view, while a patient cannot but be pleased with a remedy which soothes pain, stops cough, and prevents insomnia. Chloral does all this, and it does more—it really seems to cut short the disease, or, as it may be put, it favours an early crisis.

Having seen pneumonia treated in almost every conceivable manner, from large blood-lettings to coloured water, I have no hesitation in saying that, so far as I am capable of judging, the treatment of pneumonia by chloral is that which gives the patient most relief from his sufferings, which more than any other favours an early crisis, which so far as I know has no drawback, and, if it does not diminish the mortality, has assuredly no tendency to increase it—a negative virtue which cannot be affirmed of every other form of treatment.

I always prescribe Liebreich's chloral as the only safe form of the drug, and in pneumonia I give it dissolved in the infusion of digitalis, for its antipyretic virtues partly, but mainly to have the heart well in hand. The dose of both drugs must vary with the age of the patient: for an adult I give half an ounce of the infusion of digitalis every four hours; of the chloral I give 20 grains for the first dose and 10 grains every four hours subsequently; and these doses must be continued till the temperature falls to normal, when they are stopped and an appropriate tonic administered. A jacket poultice is a useful adjuvant, though this may be very conveniently replaced by a jacket of Gamgee tissue. An appropriate diet cannot of course be dispensed with.

I have employed this treatment for over twenty years with the greatest satisfaction, and all who have used it on my recommendation have been well pleased with its results. It does not cure all cases—nothing can do this—but it relieves the suffering of all, and many appear to have to have the disease cut short. If we get the patient within twenty-four hours of its onset, and begin with 20 grains of chloral, the first dose often suffices to remove both pain and cough; the patient dozes all day and sleeps sound at night; the rusty glutinous sputa either cease entirely or become changed to a scanty mucous phlegm, easily expectorated; the pulse drops; the temperature falls; the disease is arrested, and the patient gradually convalesces. If the disease is farther advanced before treatment is commenced a longer time may be required to produce an equally satisfactory result. In all but the most serious cases the chloral treatment is successful, and even in them it confers a relief obtainable under no other form of treatment, and in fatal cases this amounts to a veritable euthanasia.

IX.—CHRISTIAN BAUMLER, M.D.,

Professor of Pathology and Therapeutics in the University of Freiburg. PROFESSOR BAUMLER said he would confine his remarks to the question of using cooling measures—the cold bath, cold

wet packing, etc.—in the treatment of pneumonia, and more especially to the question whether these measures were merely symptomatic or curative ones—meaning by the latter term such measures as were likely to assist the organism in its endeavours to get rid of an infectious disease. Roughly speaking, the means the body avails itself of for that purpose were phagocytosis, the casting out of the products of the disease and of the microbes, and the generating of anti-toxic substances. The speaker passed rapidly in review the various changes that are produced by cooling measures on the circulation (increase of blood pressure, slowing of the heart's action, increase of secretions, especially of the kidneys, liver, and other excretories), on the respiration (deepening and slowing it), on the nervous system (causing sleep, quieting restlessness, creating desire for food and drink), and from these effects he came to the conclusion that cooling measures were not merely antipyretic and symptomatic measures, but that they fell in with the natural processes which led to the spontaneous cure of the disease. Statistics also conclusively proved the good results of such treatment, another very important effect of which was, considerably shortening convalescence.

X.—T. CLIFFORD ALBUTT, M.D., F.R.S.,

Regius Professor of Physic, University of Cambridge.

PROFESSOR CLIFFORD ALBUTT considered that the disease was not due to a single cause, but to the combined effect of the micro-organism and the antecedent cause. He then referred to the question of leucocytosis as a diagnostic sign. In his opinion leucocytosis was more marked in the pure than in the mixed forms of pneumonia. He then referred to the use of oxygen, but did not consider that it was of very much value. With regard to drugs, in his opinion perchloride of iron in large doses was a valuable remedy. Finally, he alluded to the importance of bearing in mind the fact that after the crisis had occurred the conditions were still unaltered with regard to the lung, and hence the patient required still to be treated with the utmost care.

XI.—G. A. GIBSON, M.D., F.R.C.P.Ed.,

Assistant Physician, Royal Infirmary, Edinburgh.

DR. GIBSON stated that he had intended to confine himself in the few remarks which he proposed to make to the question of leucocytosis in pneumonia, but that he could not allow the expression of opinion made by Dr. Pollock to pass without, like Professor Clifford Albutt, recording his dissent. Although speaking purely from the clinical point of view, he felt impelled to state frankly that he was one of those who regarded the work of the bacteriologists as of the highest value, and he might as a simple illustration of his meaning merely mention that although clinicians had for well nigh a century been observing cholera, they had to await the work of the bacteriologists before knowing the cause of that disease. He thought it his duty, therefore, to deprecate the line of argument adopted by Dr. Pollock. In regard to leucocytosis as seen in pneumonia, it appeared to him to be only part of a wide subject. Leucocytosis was seen as a physiological occurrence during healthy digestion, and also during pregnancy. It was found in acute and chronic suppurations, in carcinoma and sarcoma, as well as in rickets; it was, therefore, of variable causation, and it was a most interesting fact that in such acute cases as scarlet fever it was not present. Experimentally it could be induced by the injection of staphylococci and streptococci, or their toxic products. Now, believing that the leucocytes had their origin in lymph tissues, and that some of them when entangled in the bone marrow, and even possibly to a certain extent in the spleen under certain conditions, received an endowment of haemoglobin so as to become haemocytes, it was evident that leucocytosis might be brought about by over-production or under conversion—which of these predominated it was difficult to say. From the practical standpoint he was inclined to think that those cases of simple lobar pneumonia in which leucocytosis was most pronounced were those in which recovery was most common, and he cited one instance out of many under his care in the Royal Infirmary of Edinburgh, that of a feeble woman, who, in spite of a double aortic lesion, made an excellent recovery from a severe attack. In her case the ratio

of white to red blood corpuscles was 1 to 70. Holding this opinion he could not but have a leaning towards the view that the leucocytes might have conservative functions; and, without committing himself to the fascinating doctrine of phagocytosis, he thought it likely that the white corpuscles might have the function of destroying the toxins circulating in the blood.

XII.—J. SINCLAIR COGHILL, M.D.,

Senior Physician to the Royal National Hospital for Consumption, Ventnor.

Dr. COGHILL considered that the time had come to revise the terminology of the various morbid processes grouped under the generic name of pneumonia. They were at present unscientific and misleading. This was especially the case with the terms "lobar" and "lobular" pneumonia, applied to two diseases differing essentially in course, gravity, and histological elements. The terms "lobar" and "lobular" merely indicated the extent to which the lung was affected in two markedly differentiated diseases. The term "pneumonia" should be confined strictly to the "croupous form." The designation "croupous" should certainly be discarded, as it was entirely inappropriate. What is now called "catarrhal pneumonia" would be much more correctly described as "pulmonary catarrh," while "septic pneumonia" would be better named "secondary pneumonia" or "infective pneumonia." With reference to the etiology of the disease he did not think the relation of the chill to the subsequent morbid process was sufficiently investigated. The important rôle it plays in the inception of pneumonia is very far from being satisfactorily explained in this and other diseases, such as the malarial group. The rapidity with which the symptoms develop and extend after the rigor is very remarkable, whether or not due to the rapid extension of microbial invasion, as discussed by Dr. Pollock. As regards treatment the indications were afforded by the general constitutional state, and by the interrelation of the cardiac and pulmonary circulations. We had the heart pumping blood under increased pressure into the lung already congested; it was therefore necessary up to a certain point to reduce the force of the heart, with a view to limit further congestion. In what were called the "good old times" this was done by free blood letting; we could now accomplish the same purpose by lowering the cardiac energy with the judicious employment of drugs, especially aconite, and, as the expression went, "to bleed the patient into his tissues." But a point is reached when reaction sets in, and the fatigued heart tends to fail. Then comes the necessity for reversing the treatment, and restoring the cardiac energy with digitalis and other appropriate tonics. And this is further indicated as a means of helping to remove the exudatory products. It is to be remembered that heart failure is by far the most common mode of death in pneumonia. He briefly related his personal experience of two grave attacks of pneumonia in illustration of these views. The sequelæ of the so-called "croupous and septic pneumonias," whether in the form of abscess, excavation, or limited empyema, present favourable opportunities for successful surgical interference in the form of "costal resection." He had found them singularly tolerant of manipulation and amenable to treatment.

XIII.—FRANCIS HAWKINS, M.B. Edin.,

Physician to the Royal Berkshire Hospital, Reading.

Dr. HAWKINS said: Some few years ago, when writing on pneumonia, I defined it as "an acute infective disease consisting of an inflammation of the pulmonary tissue in which, from the presence of fibrin and leucocytes within the alveoli and smaller bronchi, the whole or the greater part of one or more lobes is rendered solid." A more extended clinical study of this disease has led me to become still more convinced that pneumonia is an infective disease, but whether the cause is due to the direct influence of any active organism or whether it be due to some injurious product or both I am not able to say. My reasons for regarding this disease as infective were based upon two clinical facts: first, because we find that many varying physiological functions become disturbed, or I may say that there are many indications of the approaching pathological changes which we term croupous pneumonia long before any actual change in the lung manifests itself by recognised physical signs; even one of the

earliest physical signs—I mean a dull tympanitic note—is not present, or I should say may not be present till some time after many general physiological disturbances have been present; more especially is this noticed in children, where sometimes not even until the crisis is passed are any definite physical signs discoverable, and yet for days the child may suffer from vomiting, drowsiness, and even diarrhoea. Then, again, one case recently under my care had a temperature two nights following of 107.4° before any definite sign of pneumonia could be discovered. Secondly, we have evidence of the pulmonary consolidation existing for—I think if my memory serves me, the longest period of time has been forty days when all evidence of fever has left. That chill is intimately associated with the onset of pneumonia there is in the records of clinical cases abundant evidence, but I have myself often wondered if the chill felt, and often thought to be due to change of temperature, has not really been due to the poison—the parasite. In fact, the chill is the early evidence of its onset. In the notices of this discussion no mention was made as to external violence or injury in reference to etiology. The fact that injury has in many instances preceded pneumonia is to my mind of some interest, not only as being a cause in the same sense as chill, but because the association of an injury as preceding pneumonia may be analogous to what we meet with as surgical scarlet fever—another disease which is certainly infectious and more than probably infective. In the paper to which I alluded some few minutes ago I made mention of six cases where injury was the antecedent of pneumonia. In the *Lancet* of January 20th, 1894, Dr. Paterson, of Cardiff, records five cases, and the late Dr. Hadden, assisted by Dr. Hector Mackenzie, in an analysis of 708 cases, found 17 instances where accidents preceded the pneumonia, and were considered to be causal rather than accidental. The lung change is, I think, due to, if not caused directly by, the infective process. As to the communicability of pneumonia I myself have no data. The *Analysis* by the late Dr. Hadden contains notes of cases in which two or more persons in the same house were attacked, and in current literature one is familiar with examples of probable infection. It may be so in some cases, but certainly not in all; neither does it, I think, necessarily follow that an infective disease must be infectious.

XIV.—D. B. LEES, M.D., F.R.C.P.,

Physician to St. Mary's Hospital and Lecturer on Medicine to the Medical School.

Dr. LEES said he would confine his remarks to the question of treatment. Two points seemed to him of special importance. The first was the necessity for obtaining sleep during the first three or four nights of the disease, and of obtaining it by means of drugs which should not depress the heart. The second was the great value of venesection in the later days of the disease when a small pulse, a congested or pale face, and great dyspnoea indicated approaching paralytic distension of the right heart. With regard to the use of the ice-bag, he claimed that: (1) It relieves pain very quickly and is pleasant to the patient. The cold is anæsthetic, and is hardly ever objected to, after the first few minutes. The constrained position is sometimes complained of, but this can easily be obviated by the nurse. (2) It dilates the superficial vessels. (3) It improves the physical signs locally. Very evident improvement in resonance over the area where the ice-bag has been applied may often be observed even after twenty-four hours; this he had often found. He had also observed the vanishing of bronchial breathing, and the replacement of sharp crepitation by moist double râles. He had also seen scanty viscid sputum become more watery and more copious. (4) It reduces temperature, and (what is of greater importance) it often reduces the frequency of the pulse. (5) By its sedative action it often enables the patient to obtain sleep without hypnotics, and by the improvement which it causes in the inflamed lung it obviates the necessity for venesection. (6) It secures a more rapid convalescence. Failure to obtain improvement by the use of ice is usually the result of too great timidity on the part of the physician. There is a question of dose involved, just as in the case of drugs. No one would expect to cure malaria by a single grain of quinine, or tertiary syphilis by two grains of iodide, and in the discussion on the treatment of diph-

theria, great stress was laid on the necessity of a sufficient dose of antitoxin. Similarly with regard to the external use of ice. The lung is a large organ; an ice-bag covers only a small area. Even in babies two ice-bags are often necessary, in adults three or four, if the treatment is to be fairly tested. Further proof of the local influence of ice in repressing visceral inflammation may be easily obtained by observing the rapid cure which it effects in acute sciatica, and the quick disappearance of a pericardial or pleural rub in cases treated with it. And the microbic nature of pneumonia offers no difficulty in the acceptance of the local action of ice, for Dr. Burdon Sanderson has pointed out that the pneumococcus is specially susceptible to changes in its environment. In the use of this treatment for young children certain precautions are advisable. Two hot water bottles should first be placed in the bed, to keep the lower limbs and abdomen thoroughly warm. The temperature should be taken every half-hour for the first three hours, then hourly. If any blueness of the hands or lips is noticed, the ice should be removed for an hour, and afterwards it should be applied for two- or three-hour periods with one- or two-hour intervals.

He briefly referred to three cases in illustration. The first was an infant, aged 16 months, now under his care in the Hospital for Sick Children, Great Ormond Street. Three hours after the application of an icebag over the inflamed lung the pulse-rate had fallen from 180 to 140, and the temperature from 103° to 98.4° ; the ice was then used for two-hour periods with intervals of the same length. During each application the pulse fell by twenty beats or more, and the temperature about two degrees. During each interval the pulse-rate became increased by twenty beats, and the temperature again rose. This occurred five or six times in succession, and afforded striking evidence of the effect of the ice. Along with this there was very slight spread of the inflammation and speedy arrest of it.

The second case was that of a girl, aged 9, under his care in St. Mary's Hospital. On admission she had a greatly dilated heart, probably due to previous pericarditis and fresh pyrexia. In a few days a loud pericardial rub was heard at the base of the heart. Under the use of salicylates, leeches, and an ice-bag, rapid improvement was obtained, but some hours later she was worse, a loud rub was audible over the whole heart, and in addition there was pneumonia at the left base, with dulness and bronchial breathing. The temperature was subnormal, and it was an anxious question whether the further use of ice was possible. But two similar cases in young children, in which the ice had been omitted on the addition of pneumonia to pericarditis had both died, and he therefore determined cautiously to push the treatment. This was made possible by the zeal of the house-physician, Dr. Gordon, who watched the case all the night. He was able to keep the ice-bags on for three-hour periods, with one-hour intervals, four more leeches having been first applied. When Dr. Lees saw her next morning, the bronchial breathing had vanished and the pericardial rub was much softer. She improved rapidly and steadily from that time.

The third case was one which he had published some years ago, in which pneumonia attacked the only working lung of a boy in whom the other lung was collapsed from old emphysema, as was proved on *post mortem* examination three months later. Dulness, bronchial breathing, high temperature, and rapid cyanosis proved the advent of pneumonia. Yet by early and persistent application of an ice-bag the spread of the pneumonia was arrested, and the child recovered from what, apart from the ice, must have been a fatal attack.

Dr. Lees concluded by urging the members of the Association to give a careful, patient, and sufficient trial to this plan of treatment.

XV.—F. M. POPE, M.D.,

Physician, Leicester Infirmary and Fever House.

Dr. Pope had seen that, in a ward containing several typhoid patients free from pneumonia, if a case of pneumonia was introduced, in a few days other cases would arise. He thought that these were undoubted cases of infection, and considered that under such circumstances the cases having pneumonia should be isolated. He also referred to the benefit he believed he had observed to follow the use of

spiritus etheris nitrosi, and stated that he had endeavoured to substitute a more stable nitrite for the ethyl nitrite of this preparation, but found that a similar benefit did not follow the use of sodium nitrite in 1- to 3-grain doses, owing, he supposed, to its less diffusibility.

XVI.—R. SHINGLETON SMITH, M.D., F.R.C.P.,

Senior Physician, Bristol Royal Infirmary; Lecturer in Medicine, University College, Bristol.

DR. SHINGLETON SMITH called attention to the statistics of Pétresco, of Bucharest, whose mortality in a series of 1,300 cases has amounted to only 2 per cent., and urged that in a disease of which the usual mortality is 1 in 5, it is quite justifiable to push an active drug like digitalis to even toxic doses rather than to leave the patient to the natural history of such a fatal disease.

XVII.—WILLIAM SQUIRE, M.D., F.R.C.P.,

Physician, St. George's, Hanover Square, Dispensary.

DR. WILLIAM SQUIRE said he could wish the discussion had been more restricted to acute lobar pneumonia. He showed at Manchester years ago how frequently this form of pneumonia occurred in children. Since then he had seen convalescence as rapid, complete, and surprising as any recorded in books or described by Dr. Lees as resulting from ice treatment. The name of croupous ought not to be longer applied to this form of pneumonia. It was used at first abroad under a mistake. It is misleading, and confuses our views of pneumonia. Clinically neither croup, diphtheria, measles, or influenza are ever followed by what has been so inaptly called croupous pneumonia.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

DISLOCATION OF PERONEUS LONGUS TENDON.

As attention has recently been drawn to this accident by Mr. Walsham (BRITISH MEDICAL JOURNAL, November 2nd), and as it is of very rare occurrence, the report of a case in point may prove interesting.

Mr. A. B., aged 26, out with a party of friends in September, 1894, was playing a game which consisted in "hopping" a considerable distance, when suddenly he felt something give way in his ankle with a very audible snap, and it seemed as though, to use his own words, he had been struck violently on the ankle with a stone. He was unable either to walk or stand, and had to be removed to his home in a conveyance.

On examining the ankle twenty-four hours afterwards, there was slight swelling and discoloration behind the external malleolus of the right foot but no fracture was found, and to all appearance only signs of a slight sprain. On forcibly extending the foot, the tendon of the peroneus longus was felt to leave its groove behind the malleolus and to lie on its external surface; it could be easily replaced, but not so easily retained in its proper position, if the foot was extended. The external malleolus was very prominent, owing partially to there being a slight condition of talipes valgus present, which latter, no doubt, partially conduced to the dislocation. The tendon was replaced and kept in its position by firmly strapping the ankle; the strapping was allowed to remain on for three weeks, the patient going about on crutches. After that time an elastic ankle was worn, and the patient allowed to use the foot a little; since then the tendon has remained in position, and the patient can walk and run without any inconvenience.

WM. ALLEN, M.B. and C.M. Glasg.,
Late House Surgeon, South Leithdale Hospital.

Barrow-in-Furness.

ASEPTIC CATHETERS.

DR. WARD COUSINS, in the BRITISH MEDICAL JOURNAL of January 19th for this year, called attention to the difficulty of cleansing and deodorising catheters, and advocated steaming them by means of a boiler capable of bearing a pressure

of 80 lbs. to the square inch, and then polishing the interior with a steel stilet. This method is effectual, but it is only suited to metal instruments, and cannot be carried out by an old man with enlargement of the prostate, who has, perhaps, to pass a catheter many times during the twenty-four hours and often at night, and who is always on the borderland of septic cystitis. To meet this difficulty, Messrs. Maw, Son, and Thompson have at my suggestion made some flexible instruments which can be cleansed and kept aseptic and ready for use with much greater ease. I have had the inner surface made as smooth and finished as highly as the outer. The urine does not wet it or soak into it. There are no roughnesses or irregularities to which it can cling and form a bed for septic organisms. Anyone who will split open an old catheter, one that has been in use for some time, and inspect the interior will see at once what I mean. If one of these new instruments after being withdrawn from the bladder is dropped at once, end upwards, into a deep bottle filled with a solution of boracic acid every trace of urine is washed out from it and replaced by the antiseptic, and the catheter is fit for immediate use again. The method is so simple that it can be carried out even in the dark, and so effectual that it is almost impossible for the most ignorant and careless to make a mistake.

Wimpole Street, W.

C. MANRELL MOULLIN,
Surgeon to the London Hospital.

SIMULTANEOUS DISLOCATION OF BOTH SHOULDERS.

C. B., aged 64, fell from a ladder in April last whilst thatching a cottage, dislocating both shoulders (the subglenoid variety), and fracturing his left thigh in the lower third. The dislocations had to be reduced under an anæsthetic, as the man was very muscular.

The progress of the case has been quite satisfactory, especially as regards the fracture, the patient having already walked with crutches six miles in one day. But the shoulders required much passive movement, which it was not easy to apply at first, as the least movement caused much pain in the fractured thigh, besides which the patient had to be kept extremely quiet to combat the shock of the accident, the effects of which lasted a long time, and he had also suffered much previously from rheumatism.

I have not met with anyone who has seen a case of dislocation of both shoulders.

CHAS. E. OLDACRES, M.R.C.S., L.R.C.P. Edin.

Doverbury.

CERVICAL RIBS.

With reference to the remarks on cervical ribs in the *EPTOMER* of October 19th, I should like to mention that I saw a lad lately with a cervical rib on each side, that on the right side being more prominent than the one on the left. The symptoms on each side consisted of a bulging prominence at the outer margin of the sterno-mastoid, just above the clavicle, with supraclavicular pulsation; while on palpation a bony tumour could be felt traceable to the spine. There were no symptoms of interference with the functions of adjacent structures, and both extremities were freely movable.

S. F. CLARK,
Surgeon-Captain A.M.S.

Canterbury.

TREATMENT OF SALIVARY FISTULA.

THE great difficulties attending the satisfactory treatment of salivary fistula are universally recognised; it has, therefore, occurred to me that the few following remarks may be of interest respecting a case lately under my care which was brought to a successful issue:

On August 9th a gentleman consulted me respecting an abscess which had opened externally on the left cheek, and from which there was a copious flow of saliva. The abscess I found was due to the presence of two decayed teeth, which I advised should at once be extracted. That a very considerable communication into the duct had been established was made evident from the facility with which fluids could be injected through the external opening into the mouth.

Having treated the abscess antiseptically until a healthy condition was established, I pared the edges of the wound and scraped the interior, on the chance of getting primary

union, which, however, I scarcely expected. I then brought the edges together by means of two barbed pins introduced at right angles one eighth of an inch from the margin, over which a figure-of-8 was made with carbolic silk, exercising at the same time as much pressure as possible, and finally sealing up the opening with gauze and flexile collodion. This dressing was allowed to remain undisturbed for forty-eight hours, during which time the patient was directed to lie on the opposite side and not to move the jaws either by speaking or eating, the food given being of the most nourishing description, but in a semifluid state.

At the expiration of this time the dressing was carefully removed. The pins were found to have set up some irritation, so they were taken out and reintroduced in a similar manner but in fresh places; they were allowed to remain for another forty-eight hours, when they were removed finally. Unfortunately union had not taken place, but the flow of saliva was stopped and the parts looked healthy. The strictest quiet was enjoined, and the cavity was lightly plugged with gauze steeped in a solution of zinc sulphate gr. ij to ʒj, with the addition of a small quantity of compound tincture of lavender. A pad of lint steeped in boracic solution was applied over all and kept in position by means of elastic suitably fitted. This was continued till October 30th, when the cavity had filled by granulation; skin was forming, and he was now practically well.

Of course this treatment is only applicable when satisfactory evidence exists as to the parotid duct being unobstructed. Had it failed I should have been obliged to establish a fistulous opening through the cheek into the mouth in the usual way, and endeavour to direct the flow of saliva from the outside opening into it—a very troublesome proceeding if it can be avoided.

Harlesden Road, N.W.

W. T. EAMES,
Inspector-General R.N. (Retired).

A FATAL CASE OF COCAINE POISONING.

ABOUT 7.40 A.M. on October 7th I was asked to see M. C., who was said to have swallowed some cocaine. On arriving a few minutes after I found a doctor in attendance and the patient dead. Her parents made the following statement: M. C., aged 16 years, arose about 6.30; after dressing she went into her father's bedroom, and swallowed some cocaine from a vial on the dressing table to allay the toothache. She then went downstairs. She had just taken two mouthfuls of hot tea when she felt faint, and in trying to go upstairs fell. She was then assisted upstairs, and sat down on a chair; she then had a convulsion and fell on the floor. Her father coming in asked her what she had been taking, and she said that she had taken cocaine for the toothache. Immediately thereafter she had a series of six convulsive fits in succession, the arms and legs being most affected, the face least; there was frothing from the mouth, towards the end blood-stained. She never regained consciousness, and at 7.30 when the first medical man arrived, he found no signs of life.

It was about 6.50 A.M. when she swallowed the drug, so that death took place in forty minutes. The quantity she had taken was about ʒij of a 10 per cent. solution, equal to gr. 12 of the salt. The large dose, the fact of its being taken the first thing in the morning on an empty stomach, and the hot tea taken immediately after, would all tend to quicken the effect. The medicine was contained in an ordinary clear glass vial, and the patient's father had procured it without any prescription. There was no post-mortem examination.

Leith.

G. M. JOHNSTON.

THE Medical Guild, Manchester, held its quarterly meeting on October 31st, under the chairmanship of Mr. Alderman Walmesley, J.P. An interim report on provident medical aid was presented by the Council. The report dealt with friendly societies' sick clubs, provident dispensaries, and medical aid associations. After some discussion it was directed to be completed and forwarded to every member a month before the next quarterly meeting. It was resolved, also, on the motion of Dr. Brierley: "That the Council be instructed to draw up a scheme of provident medical aid on the basis of a wage limit constructed on a sliding scale."

SOUTHPORT CONVALESCENT HOSPITAL AND SEABATHING INFIRMARY.

CASE OF ADDISON'S DISEASE WITH PYREXIA.

(By F. W. FISH, M.B., Ch.B. Vict., Resident Medical Officer.)

History of the Case.—H. G., aged 30, a married woman, was admitted on May 24th, 1895. She dated her illness from September, 1894, when she was confined. Up to that time she had enjoyed fairly good health. Directly after her confinement she had an attack of influenza. From this time she began to feel "weak" and "out of sorts," and had gradually got weaker. In September last she noticed that her skin was assuming a yellow hue, which never disappeared. Vomiting also began last September, and continued "on and off." There was no history of phthisis in the family nor was the patient herself phthisical.

When admitted she was thin and complained of languor and weakness. For some little time she was able to get about slowly, but soon had to take to bed.

The bronzing of the skin was well marked. The conjunctivae were not "jaundiced." Small black spots (so-called "freckles") were very evident about the body, but especially so on the back of both hands. Palpation over the right hypochondrium elicited pain, but the liver was not enlarged, nor were there any signs of malignancy. The pulse was small, feeble, and regular. She suffered persistently from chilliness, vertigo, headache, dyspnoea, and palpitation on the least exertion. Nausea and vomiting were present, especially towards the end. There was also some diarrhoea. She had lost a considerable amount of flesh during the last few months.

Microscopic examination of the blood (to exclude pernicious anaemia) showed it to be normal. The course of the temperature is shown in the accompanying chart.

Towards the end she complained of a good deal of dimness of vision. The breath and skin yielded the "cadaveric odour."

which has been described in this disease. Consciousness remained till the last. She gradually sank to a comatose condition, and died on June 14th, 1895, three weeks after admission.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

HENRY TRENTHAM BUTLIN, D.C.L., F.R.C.S., President, in the Chair.

Tuesday, November 5th, 1895.

THE NON-EXISTENCE OF "ROUND-CELLED SARCOMA" AS A DISTINCT CLASS OF NEW GROWTHS.

DR. HERBERT SNOW, in reading a communication on the above subject, made the following observations: A generation since, the term "soft cancer" was loosely applied to any malignant tumour of soft consistence, no matter from what tissue it had sprung. At the present day, the word "sarcoma" is frequently used in a similarly vague sense; and in particular "round-celled sarcoma" may denote almost any rapidly-growing mass of round or oval cells, whose origin is often doubtful. The lesions thus designated fall into 3 groups, and are either (a) carcinomata, (b) lympho-carcinomata, or (c) blastomata. Of the first, the huge encephaloid cancers of the female breast are the type. There is only slight concurrent enlargement of the axillary glands. Examined at the core, they consist of a loose mass of cells and cell debris, with little acinar structure. A thin section, however, from the growing margin will display the familiar acini of mammary carcinoma. True sarcoma is rather rare in the breast, except in association with cysts. The second group, lympho-carcinoma, springs from adenoid tissue in some form or other, to which appertains the bone marrow. As well as in the more external lymph glands, the growth may develop in those of the abdominal cavity and mediastina, in the tonsils, spleen, omentum, etc.; this variety also comprises the central tumours of bone. The third, blastoma, springs from unfixed embryonic vestiges; it may very largely consist of round-celled parenchyma, but this is most commonly mingled with other structures—tubules, cysts, acini, etc., its favoured sites are the kidney, ovary, and other derivatives of the Wolffian body. After careful study for many years past of all the specimens which presented themselves, the author had been forced to the conclusion that no tumour solely composed of round cells originates in the connective tissues. That every sarcoma properly so called contains abundant spindle-celled tissue, or spindle cells ranged in bands; and that none can be held genuine without this pathognomic badge.

MR. BOWLEY criticised the speaker's position by saying that the question was one of the use attaching to terms; what Dr. Snow had exhibited as round-celled sarcoma, he should name carcinoma, and what was exhibited as sarcoma he should call sarcoma. He did not for a moment allow that the only form of true sarcoma was spindle-celled; and he denied that connective tissue was always present in round-celled sarcomata. That melanotic carcinomata at times arose in the skin was proved, but this did not show that none of the melanotic tumours arising in this situation were sarcomata.

MR. W. G. SPENCER remarked that melanotic carcinomata was not uncommon in pug dogs, arising in the skin. In regard to the unique position Dr. Snow claimed for spindle-celled carcinomata, the round-celled forms were transitional towards such. The term "blastoma" he thought of no real value; a growth was epithelial or it was of connective tissue origin, or it was of both, and it could be named accordingly, without adopting so ambiguous a word as "blastoma."

MR. JACKSON CLARKE agreed with Mr. Bowley that Dr. Snow's specimens had been named in an inverted order, and that the growths called sarcomata were carcinomata, and vice versa.

THE PRESIDENT remarked that he could have followed the author had he exposed the difficulties connected with the histological diagnosis of round-celled sarcomata, and that was the subject he expected to have heard discussed.

DR. SNOW, in reply, maintained that every melanotic

tumour arising in the skin must be an epithelial growth, since only the normal epithelial cells were pigmented, and so every pigmented tumour of the eye must be a sarcoma, since there was no pigmented epithelium in this situation. The term blastoma he held to be a useful one to cover the very complex forms of new growths met with in infancy and childhood.

NOTES ON THE OCCURRENCE OF LARGE QUANTITIES OF HÆMATOPORPHYRIN IN THE URINE OF PATIENTS TAKING SULPHONAL.

Dr. ARCHIBALD E. GARROD and Mr. F. GOWLAND HOPKINS, after pointing out that hæmatoporphyrin was present in traces in normal urine, and in larger amounts in many morbid conditions, proceeded to discuss its occurrence in much larger quantities still in the dark red urine of some patients who have, as a rule, taken sulphonal for some time. The evidence connecting this with sulphonal was discussed, and an epitome was given of the associated clinical symptoms and *post-mortem* appearances in the published cases. The patients are nearly always women who have taken the drug without ill-effects for weeks, months, or even years previously. Abdominal pain and vomiting are prominent symptoms, and death in collapse frequently follows shortly upon the onset of the symptoms, which may only develop after the drug has been discontinued. Alkaline treatment appears to have been useful in some cases. Clinical histories of three cases (of women taking sulphonal), supplied by Drs. J. Delpratt Harris, W. M. Abbot Anderson, and M. J. Nolan were then given. All the cases ended fatally, but no *post-mortem* examinations were made. In one instance sulphonal had been taken for four years, and in another the symptoms only commenced ten days after the drug was stopped. The authors then gave a detailed account of the general and spectroscopic characters of the dark red urines of these patients. Tube casts were present in each instance. Even the trace of iron found in normal urine could not be detected. Various methods were employed for the extraction of the hæmatoporphyrin, and it was found that the soda and ammonium chloride methods, which work so satisfactorily in ordinary cases, were quite unable to cope with the amount of the pigment present in these specimens. Repeated extraction with acetic ether was found very useful for the partial separation of the abnormal pigments present. In each instance the colour of the urine was only in part due to ordinary hæmatoporphyrin. In one case there was present much of a pigment derived from hæmatoporphyrin, which yielded two absorption bands like those of oxyhæmoglobin. In a second case another derivative of hæmatoporphyrin was found, and in all the dark tint of the urine was largely derived from a reddish-brown pigment, such as was observed by Hammarsten, which yielded no spectroscopic absorption bands. The views of Stokvis as to the origin of urinary hæmatoporphyrin were referred to.

THE RELATION OF BILIARY CALCULI TO MALIGNANT DISEASE OF THE LIVER.

Mr. CECIL BRADLES observed that the origin of gall stones was still wrapped in mystery. By some it was held that the predisposing cause was inspissation of the bile, due to obstruction. This question, however, he did not intend to discuss, but to speak of the relation between biliary calculi and malignant disease of the liver. There were two chief views held upon the subject: one, that the carcinoma was caused by the calculi—the irritative theory; the other, that the new growth, by leading to obstruction, produced inspissation of the bile, and so the formation of the calculi—the concentration theory he might call it. It was of paramount importance to distinguish between primary and secondary carcinoma. Secondary growths were widely scattered; primary arose in the neighbourhood of the gall bladder. The secondary carcinomata were not associated with gall stones in any notable proportion, and the coexistence of the two might be held as a coincidence merely. On the contrary, in most cases of primary carcinoma there was an association with calculi. The author held the view that the irritation set up by the calculi was an exciting cause of the new growth, though these were probably not the only sources of irritation. Nevertheless, a great number of instances in which biliary

calculi were associated with carcinoma could be cited, and the proportion in which malignant disease arose was perhaps not greater than that in which carcinoma of the lip followed upon smoking. Especially in aged females were gall stones found after death, and this where there was no history of any such disease during life; the percentage in males was considerably less. He then proceeded to give details of the instances of association as collected by himself.

Mr. S. G. SHATTOCK, in commenting on the paucity of histological details, recalled the fact that carcinomata of the liver were of two kinds: columnar-celled, arising in the ducts and gall bladder and polyhedral celled, arising in the secreting tissue. Did the disease arise in the gall bladder evidence of this would be afforded by the histological characters of the new growth.

Mr. W. G. SPENCER likewise pointed out that the author had confused carcinoma of the gall bladder and carcinoma of the liver, the two not being synonymous.

Dr. VOELCKER also maintained the importance of this distinction. In all the cases of primary carcinoma of the gall bladder he had seen, there were biliary calculi. The growths themselves were columnar-celled in kind. In no instance of primary carcinoma of the liver itself, however, had he seen gall stones. In his judgment the great commonness of gall stones and rarity of carcinoma of the gall bladder militated against there being a causal relationship between the two.

Mr. BRADLES, in reply, stated that in his detailed report he had given the histological details of the cases; in the thirteen examples he recounted the origin of the growth appeared to be in the neighbourhood of the gall bladder.

Mr. BRADLES: Ureter Obstructed by Calculus.—Dr. WILLCOCKS: Perihepatitis and Thrombosis.—Dr. WALSHAM: Pulmonary Stenosis.—Mr. EDMUNDS: Myxoma of Breast.

LIVERPOOL MEDICAL INSTITUTION.

CHAUNCEY PUZEY, F.R.C.S., President, in the Chair.

Thursday, October 31st, 1895.

A METHOD OF PRODUCING RAPID DELIVERY IN PUERPERAL ECLAMPSIA.

Dr. T. B. GRIMSDALE related a case in which delivery was effected by deep incisions made into the cervix. Before the operation the os would just admit the finger; as soon as the incisions were made the forceps could be applied, and a living child was extracted in three or four minutes. The incisions were four in number, radiating from the centre of the os and at right angles to each other, and extended from the os through the cervix to the vaginal reflection.

Dr. BRIGGS thought that in many cases so rapid a withdrawal of the uterine contents would not be desirable.

Drs. IMLACH and DAVIES also made remarks.

VILLOUS TUMOUR OF THE BLADDER.

Mr. NEWBOLT showed a young man, aged 21, who had been under his care at the Stanley Hospital since June, 1894. For three years he had great pain on micturition, with sudden stoppage of the flow and frequent passage of blood. A sound detected a soft substance in the bladder which easily bled. On several occasions the bladder was opened above the pubes, and a quantity of villous growth could be seen surrounding the orifice of the urethra, and covering the whole surface of the mucous membrane except at the summit. Removal of considerable portions of the tumour was made from time to time with a Volkmann's flushing spoon, the hæmorrhage being controlled by very hot water. The last operation was performed in April, 1895, and the patient had now much improved in every respect, but still had occasional sharp pain in the left loin. Mr. Newbolt thought this was probably due to contraction of the orifice of the ureter, or blocking of the orifice by growth causing hydronephrosis. There was now no pain on micturition and no bleeding, but a small deposit of pus.

Mr. PAUL believed that when the growth was very extensive it was impossible to eradicate it; and that in Mr. Newbolt's case the spooning operation would probably have to be repeated.

Drs. BRIGGS and ROSS also made remarks on this case.

PROFESSOR FRASER'S ANTIVENENE.

Dr. LOGAN showed the antivenene as a liquid serum and in the crystalline form.

Mr. NICHOLSON said that in Rangoon, twenty-five years ago, he came across a man who had been slowly inoculating himself with cobra poison by means of tattooing. He appeared to be quite immune against the bite of the cobra, but not from other poisonous snakes. There was no doubt as to the scientific value of Professor Fraser's work, but he doubted whether the antidote would have any practical value in India. It must be remembered that considering the enormous population of the country, death from snake bite was very infrequent, and that every case of snake bite was not necessarily fatal; on the contrary, numbers of persons recovered, and many antidotes gained great credit in consequence.

TWENTY-THREE CASES OF TYPHLITIS WITH THEIR SUBSEQUENT HISTORY.

Mr. MURRAY said that these cases were collected from the records of the Children's Infirmary since 1886. Though the numbers by no means included all the children suffering from typhlitis and under treatment during that period, they represented all the cases of which he had notes, and whose subsequent history he had been able to trace; with one exception, no case was more recent than two years ago: (a) There were 9 patients in whom there was inflammation of the vermiform appendix, with most probably a slight and strictly localised peritonitis; these all recovered under medical treatment, and remain well, though 3 of them were relapsing cases. The period that has elapsed since their admission varied from three to seven years. (b) Ten cases where there was a localised peritoneal abscess due to inflammation of the appendix, the abscess was simply opened and drained. Nine of the children remain well, the time that has elapsed since operation varying from three to six years. One died from suppurative peritonitis owing to an accident during the syringing of the wound. (c) Three cases where the appendix rapidly became gangrenous or perforated; all of them died.

Dr. GLYNN referred to the difficulty sometimes experienced in distinguishing between inflammatory induration in the region of the caecum and malignant disease.

Mr. RUSHTON PARKER said that he had seen several cases of typhlitis in adults where it became a question of abdominal section, but recovery took place under rest and opium. He was convinced that promiscuous operation was not indicated in these cases whether attended by intestinal obstruction or not.

Mr. PAUL said that in recurring appendicitis the inflammatory changes in his cases were almost entirely limited to the lymphoid structures. In his experience faecal concretions were so constantly found in the most acute and fatal cases that he thought they must be directly related to the cause of mischief. There was a class of cases in adults which could not be freed from recurring danger without operation, and the operation itself, if undertaken at the right time, was almost always successful and devoid of risk.

Mr. RAWDON referred to the difficulty sometimes experienced in children and young adults in differentiating typhlitis from morbus coxae.

Mr. LARKIN believed that there was a relation between typhlitis and enlargement of the tonsils, both being similar lymphoid affections. The recurrent cases of appendicitis were a distinct clinical group, and could only be cured by removal of the appendix.

Mr. A. DAVIS said that a high temperature and extensive induration did not necessarily call for operative interference, and he related a case where, under the influence of rest and opium, the patient made a rapid and complete recovery.

The President and Drs. and Messrs. BANKS, P. DAVIDSON, BOYCK, and ABRAHAM also took part in the discussion.

EDINBURGH ROYAL INFIRMARY.—At a meeting of the managers of the Edinburgh Royal Infirmary on Monday, November 4th, it was determined by a majority of nine to eight to use the legacies which have recently been left to the infirmary, amounting to £75,000, to pay off the debts on the institution. These debts amount to nearly £41,000. The remaining sum of £34,000 it was agreed to use towards the extension of the infirmary.

REVIEWS.

DISEASES OF THE JOINTS AND SPINE. By HOWARD MARSH, F.R.C.S. New and Revised Edition. London: Cassell and Co. 1895. (Cr. 8vo, pp. 548; 79 illustrations. 12s. 6d.)

A second edition of this book was a matter of course; and until the time comes for a third edition it is hard to see how the book could be made much better than it is now. It is clear, well arranged, full of practical work, and excellent alike for reading and for reference. The chapters on Charcot's Disease, on Bone-setters, and on the different forms of Epiphysitis, are models of good clinical teaching; and the chapters on Diseases of the Spine, now first published, are admirable. The illustrations are well chosen; the whole book is the outcome of wide experience, careful observation, and what is called "surgical instinct." It is clinical from beginning to end, and is not greatly concerned with questions of pathology. Mr. Marsh is a master of the art of telling the history of a case; one can almost see the patients and watch the treatment; and the cases are so numerous that each chapter is a perfect clinical lecture, pleasant to read, and hard wholly to forget. He has learned how to write as he would speak; and thus the book is dedicated to Sir James Paget not only in the letter but also in the spirit; it has the same purity of style, the same wealth of experience, that are so welcome in *Paget's Clinical Lectures and Essays*—which Mr. Marsh "had the good fortune to edit"—and in the writings of Watson, Hilton, and Gowers.

It is not a book made out of books, but a book out of which other books will be to some extent made. Almost all that is published by physicians and surgeons is soon forgotten and out of date; but those writings live long which are the clear records of good clinical work, properly arranged and simply written.

The rules in Mr. Marsh's book as to the duration of treatment in each disease are excellent. He is still the leader of those who oppose early excision in hip disease; and his defence of non-excision is the best that can be made of a cause that is not unlikely to fail. He is not in favour of the treatment of congenital displacement of the hip-joint by prolonged extension; but the chief reason against this treatment is not that it is useless, but that it may impede the development of the chest, or may set up a lateral curvature of the spine. The displacement of muscles or tendons by injury or disease he is prevented by want of space from considering; nor does he enter the field of orthopaedic surgery. These suggestions may find an answer in the next edition; for the present, we are only concerned to welcome his work as a most valuable and acceptable contribution to the advancement of the art of surgery.

THE SURGICAL DISEASES OF CHILDREN AND THEIR TREATMENT BY MODERN METHODS. By D'ARCY POWER, F.R.C.S. London: H. K. Lewis. 1895. (Cr. 8vo, pp. 548, with 60 illustrations. 10s. 6d.)

We have here a most careful and complete account of the surgical diseases of children and their treatment. Mr. D'ARCY POWER was already known as a good surgeon, well versed in pathology, and an excellent teacher and examiner. He now has the further distinction of being the author of a book in which surgery, pathology, sound teaching, and hard work all meet together. As surgeon to the Victoria Hospital for Children he has gained a wide experience of the treatment of their surgical diseases. He seems to have noted all his work as he did it, and has thus been able to turn it all to good account in a book full of practical rules, valuable cases, and those small hints and suggestions that are of more worth than the repetition of the great facts of all the textbooks.

Among the chapters which are especially useful come those on intracranial disease and its surgical treatment, on hernia, and on tuberculous disease of bones; this last disease being especially associated with his name. Mr. Power will never take any credit to himself that does not rightly belong to him, for he is almost too scrupulous to mention everybody whose least remark or theory he is quoting, with the result that his index (from A to C only) gives more than fifty

references to other writers. And since he is much given to the classics and to the study of history—as in his excellent account of the illnesses of Samuel Pepys and his wife—we find mention of many other notable names; he has even diagnosed the case of Philoctetes as “infective osteo-myelitis terminating in sclerosis;” though we would suggest that this diagnosis does not cover all the symptoms. But the love of Greek is the root of much evil; and we hope that in a second edition Mr. Power will avoid such words as colapsoxy, orchidopsoxy, arthrodosis, hypertrichosis, and, worst of all, osteopsothyrosis. It is certain that he must then also correct the large type and the waste space on some pages (for example, on pages 264 and 509), which somewhat confuse the reader and spoil the look of the page.

But these are very trivial defects; and he has given us a well-written, complete, thoughtful survey of the vast field of children's surgery. The book is full of good practical teaching, conveyed in a clear and pleasant style. We would quote as especially good the paragraphs on psoas abscess, and those on intubation of the larynx. We hope that in a second edition he will reconsider the term “typhoidal osteo-myelitis;” and that he will weigh again his words regarding Sayre's jackets, Lannelongue's “sclerogeny,” and the unduly elaborate treatment of burns.

The illustrations are admirable; there is a full index and an admirable list of references. We congratulate Mr. Power on a very fine piece of work, which every surgeon ought carefully to study.

DIPHTHERIA AND ITS ASSOCIATES. By LENNOX BROWNE, F.R.C.S. Ed. Illustrated by the Author. London: Baillière, Tindall, and Cox. Philadelphia: J. B. Lippincott Company. 1895.

As was to be expected, we have in the book before us a good summary of what, up to the time of the publication of this work, was known of diphtheria as regards etiology, pathology, and treatment. After giving a “definition and synopsis,” from which it may be gathered that Mr. LENNOX BROWNE is thoroughly convinced that diphtheria pure and simple has for its specific pathological factor the Klebs-Loeffler diphtheria bacillus, he gives an interesting though very brief chapter on the history of diphtheria, in which he points out that, although the disease has been known from a very early period of medical history, it had not been thoroughly studied until Bretonneau took up the consideration of the question, and published his work on *Special Inflammations of the Mucous Membranes* in 1828. From that time to the present most important contributions have been made to the pathology of the disease until 1884, when Loeffler described so fully the Klebs-Loeffler bacillus, out of which has arisen most of our present knowledge.

In the chapter on Etiology are given the various predisposing causes of the disease. This is followed by an account of what is at present known of the methods of contagion and dissemination, and also the possibility of inoculating the disease, along with which, of course, he considers the question of the relation of the diphtheria bacillus to true diphtheria. In connection with the organisms found in cases of diphtheria Mr. Lennox Browne gives a number of photographs, some of which appear to be very well reproduced. He then goes into the question of the poisons formed by the Klebs-Loeffler bacillus, and the action of these toxins on the heart and the nerves, giving in this section what has been done by Vincent P. Meyer, and Sidney Martin. As regards the morbid anatomy and the changes that take place in the mucous membrane, the author follows the general descriptions of recent observers. He describes the ordinary methods of bacteriological diagnosis, and then gives an account of the clinical diagnosis of “diphtheria and its associates.” This part of the work is rendered additionally valuable by a number of very beautiful coloured drawings made by the author from cases followed by him under Dr. Gayton's supervision at one of the fever hospitals in London. This constitutes the only really original part of the work. There are also a number of photographs of diphtheria bacilli and of the other organisms found in these cases, which cannot but be valuable as records of appearances presented by the cases described. As regards the elements of

prognosis, those dealing with the general statistics of diphtheria are interesting from many points of view, especially those in which large numbers of cases are analysed, where such method of analysis is permissible. Where, however, the data are derived from a comparatively small number of cases, they do not appear to be so entirely satisfactory. As regards treatment, Mr. Lennox Browne apparently lays most stress on local and constitutional measures directed to keeping up the strength of the patient, in which he will be followed by most of those who have to treat these cases, but we imagine that his deductions concerning the serum treatment of diphtheria will not be so generally accepted as much of the other part in this section.

In cases of laryngeal stenosis, intubation is preferred to tracheotomy, though it is pointed out that it may become necessary to perform tracheotomy in certain cases. The chapter on Intubation and Tracheotomy is one of the best in the book.

The book is well printed, the illustrations are excellent, and for the reader who wishes to have at command a good summary of what has been written on this subject, we recommend this essay with its appendix on the serum treatment of diphtheria. In the case of such a controversial question no one can expect to read what Mr. Lennox Browne has written without finding some, or perhaps even many, points with which he cannot agree, but the hundred cases which the author tells us he has studied in the North-Western Fever Hospital under Dr. Gayton, form an admirable text for the essay that Mr. Lennox Browne presents for the consideration of his medical brethren.

MYXŒDEMA AND THE THYROID GLAND. By JOHN G. GIMLETTE, M.R.C.S., L.R.C.P. London: J. and A. Churchill. 1895. (Cr. 8vo, pp. 128. 5s.)

This work first appeared as a thesis in Portuguese, and was composed to obtain the necessary qualification to practise in that country. Since then it has been amplified and written in English. The subject matter is dealt with under the heads of (1) the history, etiology, symptoms, and complication of the disease; (2) the anatomy, histology, and physiology of the thyroid gland; and (3) pathology and treatment of myxœdema. This disease is a subject of paramount interest at the present moment, as it illustrates a new departure in therapeutics which has been applied, although with less success, to other diseases. This small work furnishes a good summary of the subject; due credit is given to the various authorities quoted in it.

DIE ZUCKERKRANKHEIT UND IHRE BEHANDLUNG [Diabetes and its Treatment]. Von Professor C. VON NOORDEN. Berlin: A. Hirschwald. 1895. (Royal 8vo, pp. 212. M.5.)

The author has already obtained so wide a reputation by his investigations on diseased metabolic processes that a book from his pen on such a subject as diabetes is sure of a favourable reception. This work has already appeared in English in the *Twentieth Century of Practice*, vol. ii. It contains eight chapters arranged as follows: 1. The physiology and general pathology of sugar in the body. 2. The theory of diabetes. 3. The etiology. 4. The pathological chemistry. 5. The complications. 6. The general clinical picture, course, and progress. 7. The treatment. 8. The examination of diabetic urine for sugar, acetone, aceto-acetic acid, and oxybutyric acid.

In a book so full of investigation it is only possible in a short review to deal with a few points of more special interest. The relation of the pancreas to diabetes is discussed under experimental diabetes as well as under the etiology and treatment of the disease. It is only too obvious how imperfect our knowledge is of what has been termed pancreatic diabetes in the human subject. The author observes that by bringing all cases of diabetes into relation with the pancreas the development of our knowledge of diabetes is in danger of being restricted. Treatment of diabetes by pancreatic preparations has hitherto been but slightly encouraging.

Under the pathological chemistry the dependence of glycosuria on the kind of carbo-hydrate given, on the use of fat and

alcohol on muscular exertion, on the condition of the nervous system and digestive organs, and on complicating diseases (fever, etc.), is a matter of practical interest. The author observes that acetoneuria and diaceturia appear when for any reason the diabetic obtains insufficient nourishment. It is a pressing indication to revise the diet sheet. The excretion of oxybutyric acid of more than a few grammes and extending over a few days is of the worst significance. The treatment is given at much length, and nothing can be more important than the stress laid on the different dietetic treatment required for the different varieties of the disease.

This book simply abounds in information and is a most important contribution to a scientific and accurate study of diabetes.

NOTES ON BOOKS.

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M.D., F.R.C.P., Physician to and Lecturer on Medicine at Guy's Hospital. Fourth Edition. (London: J. and A. Churchill, 1895. Cr. 8vo, pp. 974. 15s.)—The popularity which this excellent *Manual* has obtained in early editions has been so considerable that we need do little more than announce the appearance of a fourth. The chief changes have been in the articles on the specific infectious diseases, and in the discussion of immunity and related subjects. In treating of malarial fevers, a description of the plasmodia has been introduced, and elsewhere additions have been made to the descriptions of tropical diseases. The section dealing with appendicitis has been recast, and descriptions of acromegaly and mycosis fungoides have been introduced. The work thus maintains its character as a textbook at once comprehensive and concise.

Elements of Practical Medicine. By ALFRED H. CARTER, M.D., F.R.C.P., Senior Physician to Queen's Hospital, Birmingham. Seventh Edition. (London: H. K. Lewis, 1895. Cr. 8vo, pp. 568. 10s.)—Dr. Carter tells us in the preface to this—the seventh—edition of his textbook that his object has been to provide broad truthful sketches of the various types of disease, as distinguished from a mere epitome or compendium of exhaustive treatises. The author has hit the happy mean, and has his reward in a multitude of readers. The present edition contains a section on diseases of the skin, by Mr. Malcolm Morris, who has succeeded in a few pages of clear exposition in giving the student a clue to what he too often regards as the bewildering maze of dermatology. The article will distinctly add to the value of an already popular textbook.

The Student's Practical Materia Medica. By GRACE HAXTON GIFFENS, L.R.C.P. and S.E., Senior Demonstrator of Anatomy, Ladies' School of Medicine, Chambers Street, Edinburgh. (Edinburgh: E. and S. Livingstone, 1895. Crown 8vo, pp. 88. 2s.)—This little work is a classification of the facts relating to drugs, which the student is advised to commit to memory before going in for examination in materia medica. The seven chapters into which the book is divided form an outline of materia medica, readily scanned, and which will assist the memory in retaining doses, preparations, compositions, strengths, etc., which the student often vainly endeavours to learn whilst wading through the ordinary manuals. Exception might be taken to some of the definitions, but on the whole the work is well done, and undoubtedly will be of service to candidates as a memory refresher before examination.

Bibliographie der Humanen Helminthologie. Von Medicinalrath Dr. J. Cu. HENK. Heft 9. (München: J. F. Lehmann, 1895. Demy 8vo, pp. 207 to 321. M. 3.00.)—The present number of this invaluable bibliography deals with two nematodes—*Oxystrongylus* gages and *Trichina spiralis*. As in the preceding volumes, the arrangement is excellent. The bibliography appears to be practically complete. The work is invaluable to helminthologists. It should find a place in every medical and natural history library.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DENTISTRY AND THE ALLIED SCIENCES.

TABLOIDS OF SULPHITE OF MAGNESIUM.

THE use of sulphite of magnesium as a local bactericide in the treatment of follicular tonsillitis, aphthæ, and sore throat has been recommended by Dr. Brownlow Martin. This salt, when brought into contact with mucous surfaces is decomposed into sulphurous acid and magnesia.

Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, E.C., prepare tabloids of sulphite of magnesium, which are very convenient for the purpose intended. The tabloids have rather a pleasant taste, and immediately give off sulphurous acid when moistened with water slightly acidified with hydrochloric acid.

PALATINOIDS OF PEPTONATE OF IRON AND SULPHATE OF MANGANESE.

MESSRS. OPPENHEIMER, SON, AND CO. (Limited), 14, Worship Street, E.C., have sent a specimen of their recently introduced palatinoid, containing peptonate of iron and manganese sulphate. This combination appears to be in demand for the treatment of chlorosis and anemia. The palatinoid, a kind of double convex cachet, is an excellent method of administering certain medicines; they readily open in warm water, and allow the contents to escape.

TERROL.

TERROL is a yellowish liquid of the consistence of thick syrup, somewhat resembling in appearance, especially when cooled, soft vaseline. The product is stated to be extracted from petroleum. Its characters correspond with those of the hydrocarbons of the paraffin series, which consist of a semi-solid mixture containing some of the softer or more fluid petroleum. It has been introduced by the Terrol Company, Devonshire Road, Forest Hill, London, S.E., as a tasteless substitute for cod-liver oil.

Petroleum is by no means a new remedy. In France *huile de Galian*—a similar product—has been long famous for the treatment of lung disease; its action being supposed to resemble the terebinthate or balsamic substances. The crude oil is preferred to the refined petroleum, and it is said to be a valuable remedy, not only in bronchitis, but all other mucous affections, as well as many other internal lesions.¹ Wielezyk states that the petroleum miners in the Carpathians are exceptionally free from bronchitis and diseases of the skin.² More recently the semi-solid petroleum appears to have come into use in the United States. Dr. M. M. Griffith³ asserts that the crude semi solid petroleum (red wax), as it accumulates on the casings, etc., of the oil wells, is an invaluable remedy in chronic bronchitis and incipient phthisis. Dr. N. Randolph, an American physician, has shown that these petroleum are valueless as food stuffs, and that when taken internally in doses of 3 to 4 drachms they act simply as a feeble laxative. At the present time in this country the general opinion appears to be that the semi-solid petroleum, although probably not digested or assimilated, act as demulcents or antiseptics in the intestinal tract.

Terrol is recommended as a substitute for cod-liver oil. How cod-liver oil acts is still undetermined, but there can be no doubt that great benefit is sometimes derived from its administration. What we can say positively of terrol in relation to cod-liver oil is that terrol is tasteless and odourless.

THE ELECTROTHERM.

AMONG the various uses to which electricity may be applied is the local development of heat. The electrotherm, which is now being introduced by Messrs. Witty and Witty, Limited, 88, Leadenhall Street, E.C., is intended to take the place of

¹ *Bull. et Ann. Soc. Therap.*, July, 1892, p. 100.

² *N. B.*, May, 1893.

³ *N. B.*, May, 1893.

poultices, fomentations, hot water bottles, foot warmers, etc., wherever electricity is available; in other words, wherever the electric light is in use. The apparatus is very simple, consisting of a flexible pad or sheet composed of asbestos, with an embedded wire which when attached to the socket of an electric lamp offers sufficient resistance to the current to produce a constant and uniform degree of heat. It is made either as a foot warmer for the floor, which we should imagine might, if properly regulated, be of considerable service to people with feeble circulation engaged in sedentary work, also as a foot warmer for use in bed, and in a waterproof material as a substitute for poultices and fomentations. A special form is made to take the place of the jacket poultice, for which purpose it has the great advantage of not requiring to be changed. In fact, the great benefit which is likely to accrue from the use of this apparatus is that the heat can be so regulated as to remain uniform during long periods. It can be fitted with attachments to fasten either into an ordinary plug or into the socket of an electric light burner.

TONGUE DEPRESSOR AND GUARD.

DR. ALKX. WOODMAN DOWDING, of Wanstead, Essex, has designed an attachment for a light form of tongue depressor for the protection of the face during the examination of the fauces in cases of diphtheria. The tongue depressor, constructed of stout plated wire, is well curved and generally of convenient form. Upon it is slipped a detachable carrier, which holds a small sheet of mica of the shape indicated in the drawing: the carrier slides backward and forward on a bar on the under surface of the tongue depressor. The holder for the mica plate is supported on a ball-and-socket joint, so that this shield is freely movable. It is light, transparent and easily kept clean. In cold weather it should be warmed before use.

In non-infectious cases the shield and carrier can be removed altogether. Dr. Dowding tells us that he has been led to design this tongue depressor and shield owing to the fact that on two occasions he had himself contracted diphtheria, the infection being conveyed to him by material coughed up while he was engaged in examining the patient's throat. The apparatus which he has designed is made by Messrs. Arnold and Sons, of West Smithfield, E.C. It is simple in construction, light, handy, and not likely to get out of order. It will undoubtedly afford protection against direct conveyance of diphtherial material from the patient's throat to the medical man's mouth, a mode of infection which in all probability has been responsible for a large proportion of the saddest cases of death from diphtheria among members of the medical profession.

OIL STOVES.

THE stoves of the Hygienic Heating and Lighting Company, 13, Southwark street, S.E., are good examples of the modern oil stoves now so commonly used for the heating of halls and other places where there is sufficient ventilation to allow of the dilution of the carbon dioxide produced by the combustion of the oil.

In regard to the general principles which should be borne in mind in arranging for the use of flueless stoves, we would

refer to articles which have appeared in the *BRITISH MEDICAL JOURNAL*, 1894, vol. ii, pages 1091 and 1219; and 1895, vol. i, page 119.

The stoves of the Hygienic Company named "Columbus" appear to be well-made and serviceable articles; the oil chamber is connected with the wick cylinder only by a single small tube, and the entering current of air is so arranged as to keep the chamber cool; the lamp shade is made of mica, so as to avoid risk of fracture, and within the wick tube a water reservoir is placed, with the object of preventing the dryness of air which is imagined to accompany the use of a stove. It is stated that the water evaporates from this reservoir at the rate of about 3 ounces per hour. In view, however, of the fact that, in the same time, three-quarters of a pint of oil is consumed, all the hydrogen in which is turned into watery vapour, which escapes into the air, we are not inclined to attribute much importance to the water reservoir as a hygienic appliance.

SERVICES ADMINISTRATION AND NEEDS OF THE INDIAN MEDICAL SERVICES.

[FROM THE *Madras Mail*.]

AN address was given by Mr. ERNEST HART before the meeting of the South Indian Branch of the British Medical Association, held in the Madras Medical College on February 7th, 1895.

The meeting was specially convened to welcome Mr. Ernest Hart, the Editor of the *BRITISH MEDICAL JOURNAL*, and Chairman of the Parliamentary Bills Committee of the British Medical Association. The chair was taken by Surgeon-Major-General C. SMITHSON, who is also the President of the Branch Association. There was assembled a large audience of medical gentlemen resident in Madras and the surrounding districts. Among those present were Surgeon-Lieutenant-Colonel Markey, C.B., P.M.O. Madras District; Surgeon-Lieutenant-Colonel Bevan, Secretary to Principal Medical Officer, Madras Army; Brigade-Surgeon-Lieutenant-Colonel W. Price, M.D., Principal, Medical College; Surgeon-Lieutenant-Colonel Allinson; Surgeon-Lieutenant-Colonel W. G. King, Sanitary Commissioner; Surgeon-Lieutenant-Colonel Browne, Professor of Surgery; Surgeon-Lieutenant-Colonel Hazlett, Surgeon-Major Browning, Surgeon-Major Maitland, Surgeon-Major Pope, Surgeon-Major Sturmer, Professor of Midwifery; Surgeon-Major VanGeyzel, Chemical Examiner to Government; Surgeon-Major Damla; Surgeon-Captain Robertson, Professor of Hygiene; Surgeon-Captain Williams, Surgeon-Major Poynder, Army Medical Staff; and Surgeon-Lieutenant Elliot. Dr. H. Rangappa, Dr. O. B. Rama Rao, and other leading native doctors were also present. The upper benches in the Hall were filled with the male and female students of the Medical College.

THE CHAIRMAN, in introducing Mr. Hart to the meeting, said that they all knew of the admirable work which he had done in improving the condition of the sick poor in workhouses, and in bringing about that great reform in the treatment of the sick which led to the creation of the Metropolitan Asylums Board and its hospitals in London. They knew the influence which he had exercised throughout Europe more recently. Mr. Hart had continued the same work, and was now extending reforms to the provincial workhouse infirmaries. With reference to the military service of the Army Medical Staff and Indian Medical Service, he had always been in the forefront to assist them in their endeavours and to get their service placed in such a position that they would be able to carry out efficiently the duties required from them by Government, and which they owed to the British public.

MR. HART, who was received with prolonged cheers, said: It is to me an unexpected surprise, as it is a great pleasure, not unmingled, however, with a stringent sense of responsibility, to be thus publicly welcomed by this most important Branch of the British Medical Association. It must in any case be a source of deep gratification to be the recipient of this most honourable and kind reception. We in England have long been accustomed to look upon the Indian Medical Service as representing individually the flower of the medical

profession. They are for the most part selected out of the most able of our younger graduates. Only those who feel themselves able to go through a special examination, beyond and above those which qualify for general practice in England, present themselves for the severe test by which alone the high marks which qualify for the Indian Medical Service can be obtained. Made up of the pick of the younger members of the profession, polished and sharpened for the work from their special training and subsequent examinations at Netley, they enter this service well prepared and thoroughly equipped for their work in this great field. It is not surprising that they have attained a justly high reputation for the admirable efficiency with which they perform their difficult duties, and that they succeed in rendering services to the people of India and to the British Empire which are in their character and extent quite unprecedented. We have to look only to broad facts. They have reduced the mortality of the British and Indian armies serving in this empire from 69 per 1,000 to 15. Thus they have reduced enormously the mortality of our soldiers within a very few decades. They have thus practically added to the strength of the army another army of equal size and efficiency, or, to put it, perhaps, more clearly, if less picturesquely, they have reduced the mortality, the invaliding, and therefore the cost of the army by one-half. It would be easy to amplify these figures, but it is, to you at least, unnecessary; but it is safe to say that, but for the services thus rendered, the strain upon the financial and vital resources of the empire in maintaining the army which holds India secure would be well nigh, if not altogether, unbearable. To the Indian and British medical officers serving here it is now well recognised that the empire largely owes it that it is possible to hold India without quite extravagant expenditure of life and resources. Nor are their services less in respect to the Indian Medical Service to the civil population, for we in England, perhaps, hardly realise that the Civil Medical Service of India is only the Army Medical Service under another name, and that almost, if not quite, the whole, of the enormous service rendered to the empire by the diminution of mortality in the great cities and provinces of India is also due to the efforts of the Indian army medical officers lent to the Civil Medical Department and serving under another title.

"SMASHING THE DIAL."

Perhaps I may be permitted to indulge here in a curious little reminiscence of my own early life, which not only binds me by a specially close tie to the interests of the service, but which throws one of those strange side-lights upon history that show on what small threads great events may hang. It occurred now more than thirty years ago, not many years after the first introduction of the system of competitive examination by which it was determined to be absolutely necessary to guard the entrance into the Army Medical Service of India in order to ensure efficiency. The Government found, however, that the supply of candidates for admission under the system of competitive examination was falling dangerously short and that the vacancies could not be filled. In other words, the attractions presented by the Service to men of adequate capacity were insufficient to induce suitable men to apply for the appointment. The obviously proper course was to bring the conditions of service up to such a level as to make them sufficiently attractive to adequately instructed and capable candidates. Economy dictated the opposite course, and in one of the cold fits of financial retrenchment which so frequently come over Parliamentary Governments, the Government resolved to take the retrogressive step of destroying the examinations, and going back to the old way of nomination without examination, which had so completely failed before. It was true that a century's experience had shown that such a test was absolutely necessary, and its institution was the outcome of searching inquiry and overwhelming evidence; but the fear that it would be necessary to improve the status of the medical service before candidates could be secured for examinations, sufficed to induce the Government to undo all that had been done, and to revert to the bad old days. This Bill had already passed its second reading under Government auspices when my attention was called to it. I was then a very young man, and happened to hold an important position in re-

lation to the editing of a great medical paper. There was no time to be lost, for the Bill was already down for its third reading. I took active steps and prepared a very urgent and strongly worded remonstrance for publication, headed "Smashing the Dial." I had enjoyed then the friendship of a man since celebrated for his services in the East—Mr. Pope Hennessy. I laid the whole matter before him, furnished him with details, and gave him the proof of the article, which was to be published on the following Friday. Mr. Hennessy was fired with the same indignation as myself at this reckless sacrifice of the great interests of India and the Army Medical Service generally to prejudice and to a sudden cold fit of economy. He organised a strong opposition amongst his Irish colleagues. It was a Conservative Government, and he and his colleagues formed a most essential part of the Conservative majority of that day; they acted on this occasion as a compact and independent body. Mr. Hennessy rose in his place and denounced the proposals of the Bill, and read the statement which I had put before him to the House. The Opposition suddenly organised took the Government by surprise, and strange and rare as the event is in Parliamentary history, he succeeded in defeating the Government on the third reading of its own Bill. It was by this singular incident in Parliamentary history that the competitive examinations, which have proved so highly and important an element in maintaining the efficiency of the Indian Medical Service were preserved; and thus I am able to congratulate you and to congratulate myself that by a timely watchfulness this evil scheme of destruction of the efficiency of the service was completely baffled and, needless to say, has never been revised. Since the date of my becoming an active member of the British Medical Association I have organised a Parliamentary Bills Committee, which has on more than one occasion had to act in concert with you for the securing of further means to promote the efficiency of the service, and it has been and is to me, and I am sure to the whole Association, a matter of the deepest satisfaction that you are convinced that our efforts in that direction have not been without value, as indeed your recognition on this and on former occasions of such service has sufficiently testified.

WATCHING A GREAT MACHINE AT WORK.

One of the most interesting and important incidents and conditions of my present most interesting and most delightful visit to India has been the opportunity of watching this great machine at work, of making the personal acquaintance of the distinguished men who are presiding over its activity, and of a large number of those, such as yourselves, who are the individual factors in its successful operation. I may say unaffectedly, emphatically, but without exaggeration that what I have seen and learnt after the fullest opportunities of investigation has filled me with an unmingled admiration of the surprising extent and variety of the work done, of the unstinted labour and enthusiasm with which this vast field of medical activities is covered. The Government, knowing well by experience with what unflinching devotion the medical officers of the services in India take up and carry on whatever duties are assigned to them, has not hesitated to extend the sphere of duties and to develop them in every direction, until we find Indian medical officers running through a whole gamut of performances of which few of us in England have an adequate idea, and of which certainly I had been far from forming anything like a complete conception. I venture to think, however, that the increasing urgency of great works of preventive medicine, the large development of scientific capacities and the unmurmuring acceptance by Indian medical officers of duties of whatever various kinds laid upon them, have reached a point at which the machinery is already dangerously strained, and indeed I am not sure but that it is and has been now for the last few years at a point which may be designated as the breaking point. I am deeply impressed with the fact that already and for some time the duties laid upon Indian medical officers are altogether out of proportion to the salaries allotted to their various duties, and what is from the Imperial point of view far more important, that it is quite impossible that the whole of them should be satisfactorily fulfilled otherwise than on paper.

EXORBITANT DUTIES.

At the great Calcutta Congress, which has been so conspicuous a success and so valuable a precedent, the President, Surgeon-Colonel Harvey, in his admirable introductory address, spoke emphatically on this subject, but with the careful reserve of his official position. I was able to speak with less restraint and in language of somewhat more emphatic protest, and I ventured to enumerate by way of illustration the exorbitant list of duties imposed upon individual officers in the N. W. P. and in Bengal within my own recent observation. In one instance which I quoted there were fourteen separate kinds of duty imposed upon one gentleman having a million and a quarter inhabitants under his sanitary supervision. He had been called upon to administer a gaol of 1,200 persons, to supervise a great number of dispensaries, to check and to be responsible for the vaccination of the whole district, to perform duties as police medical officer both civil and military, to superintend a great lunatic asylum, to preside over a medical school, and under strict injunction never to be absent more than seventy-four hours at a time from his residential centre. Happily this list and this illustration have attracted attention at home and throughout India, and have been much commented on in official and unofficial circles and by the newspapers. Happily, too, it has excited critical comment in the leading journal of Great Britain. In one of those most able series of weekly letters on Indian affairs in the *Times*, the writer, without denying the facts, deprecates any change on financial grounds, and alleges that this sort of thing is common throughout the whole Indian administration, and that Indian medical officers, like other officers, must be expected to be thus loaded beyond European precedent with unlimited variety and extent of work. I have a profound respect for the remarkable ability and the encyclopædic knowledge which characterise the authorship of these articles. I will not, therefore, attempt to discuss what may or may not be the range of duties in other departments. But I wish only to say that no reasonable human being who is at all cognisant of the possibilities of human endurance or the contingent possibility of the efficient performance of the range of duties enumerated can possibly believe that any one man could do the work here allotted.

DEPARTMENT STRAINED TO BREAKING POINT.

And the fact is that, overwhelming as are the labours of Indian medical officers in civil employ, it may be fearlessly affirmed that the present strain put upon the energies of the Service is quite beyond its endurance, and ensures that the work shall in a great many of its departments be performed on paper rather than in reality. In order to determine how far this condition is general, I have availed myself of the unusual opportunities which I have enjoyed here for investigation and independent criticism to ascertain whether the instances to which I referred were unusual or not. I find the same state of things to prevail in South India as in the North, and in this great Presidency as in those to which I have referred. Let me give you a few details only of what I find to be the state of things in this great medical centre of Madras, a premier Presidency and one of the greatest centres of medical instruction and activity.

IN THE MADRAS PRESIDENCY.

Here are a few examples of the amount and variety of administrative and expert duties assigned to medical officers in civil employment:

1. The Surgeon of the First District is expected to perform the following duties: The supervision of 132 inmates at the Monegar Choditry, a poorhouse for natives. He is the Superintendent, and has medical charge of the Rayapuram Native Infirmary, with 104 beds, with an average daily sick of 60, and a total treated of 3,045 in 1893. He has the supervision of the North Black Town Dispensary, with a daily average attendance of 235, and a total admission of 4,428 in October, 1894. He gives clinical instruction in medicine and surgery and midwifery to 141 native pupils of the hospital assistant class, in their first and second year of study; in this he is assisted by an assistant military surgeon. He has the supervision and medical charge of Sir Savalay Ramasawmy Moodeliar Lying-in Hospital with 36 beds. He has the super-

vision and medical charge of the Government Leper Hospital with 308 beds, nearly always full. He has the supervision and medical charge of the Criminal Leper Wards with 32 beds. He is assisted in this work by the civil apothecary. He has also the medical charge of the Civil Debtors' Gaol, the average number confined in which is about 30. He is the Medical Inspector of Emigration for the Natal and Mauritius Depôts, and has the medical responsibility for the embarkation of coolies, of whom in 1893 and 1894, 1,843 embarked and 163 returned from Natal. From Mauritius in the same period 115 embarked and 811 returned. His district medical work includes the granting of health and sick certificates to Government servants. In 1893, 233 health certificates and 103 sick certificates were granted. Cases for a Medical Board numbered 132. He is also the medical attendant on Government servants drawing above Rs.200 a month residing in his district. He has, finally, the medical charge of the Police Lock up in Black Town. His work occupies him daily from 7 A.M. to 12.30 P.M., without taking into consideration the evening visits he has to pay.

2. The Professor of Anatomy is also the Fort Surgeon and Fort Sanitary Officer. He is the Port and Marine Surgeon, Port Health Officer and Inspector of Seamen. His duties include attendance on the officers and non-commissioned officers of the district staff and their families who reside in the Fort; the medical attendance on the warrant and non-commissioned officers and their families residing in the Ordnance Camp, Equipage, and Commissariat Lines and H. E. the Governor's Band, the whole consisting of 7 officers, 76 men, and 198 members and their families. He is assisted in these duties by a selected military assistant surgeon, who is borne on the strength of the Station Hospital. He has also the medical charge of the Fort Dispensary, which is situated in the Government quarters occupied by him in the Fort, where all the sick followers of the Ordnance and Military works, who report sick are treated or are transferred to the General Hospital. These followers number about 550, with a daily average sick of about 20. He examines these followers upon their enlistment and before they proceed on field or foreign service. As the Fort Sanitary Officer he has periodically to inspect the whole Fort and its surroundings. These duties take an hour daily of his work. As Port Surgeon and Port Health Officer he has to inspect the vessels before granting bills of health. This duty varies according as there is an epidemic prevalent in Madras or not. He has also to inspect all vessels arriving in Madras with a contagious disease on board. The number of bills of health granted during the past three years averaged 62 to 82, and would be more only that some of the most important steamer companies are satisfied with bills of health for steamers being endorsed. During an epidemic in Madras, however, these duties are greatly increased. Another duty he has to perform is the superintendence of the Port Dispensary, which is in the subordinate charge of a civil apothecary, who assists generally in the Port duties and attends all cases of accident or emergent sickness brought to him or to which he is called. In addition, the most important duty of all with which he is entrusted is that of Professor of Anatomy, which requires him to lecture an hour daily during the week. In this connection of course he has also the supervision of dissections and the dissecting room. He has, however, the assistance of a demonstrator.

3. The duties of the Civil Surgeon at Cochin are as follows: He has to look after a European and Eurasian population consisting of 1,312 souls. The Municipality, of which he is the Medical Officer, has a population, including the *talug*, of nearly 20,000 souls. The Municipal Hospital has an average daily sick list of from about 125 to 150 out-patients, with 3 in-patients. The number of major operations in 1892 was 95, in 1893 it was 67, and in 1894 it was 89. About 1,000 British ships call at the port every year, and there are very often over 200 native craft in the backwater, of which he, as Port Surgeon, has the supervision. Cochin is moreover liable to frequent epidemics on account of the lax supervision there is over these native craft and boats coming from the native States. The number of bills of health he had to give to ships in 1894 was 59. He has to attend to all cases of serious accident or sickness when a ship arrives in port. He has also the charge of the sub-gaol and supervises the Passport Lazaretto, which

without fear of contradiction even from your respected Chairman, whose official position is for the moment not at all in question, but who has certainly good opportunities of knowing facts. For the actual work of this Presidency it cannot be doubted, and I believe it is indeed well known to all, that at least another fifteen medical officers are required even to carry on the work of the Presidency and of the Indian Army Medical Service here, on its present scale and with its present heavy requirements. Men cannot get furlough. Duties of the highest importance have to be carried on either in a perfunctory manner or at the cost of excessive labour and of great injury to health.

SPECIAL HARDSHIPS.

There is much more that I should like to say to you, but my time is drawing to an end, and I fear I must now cease. (Loud cheers and cries of "No, no," and "Go on.") Well I cannot allow myself to trespass much further on your time; but I should like to say a few words as to the special hardships which, most unwisely in my opinion, and I think in the opinion of everyone who calmly examines the subject, the Government now inflict upon the British and Indian Medical Services. The British army medical officer serving in India is from the very outset heavily mulcted by the mere fact of being called upon to serve in India. It is an astonishing fact that at the present moment every young medical officer, surgeon-lieutenant, receives £30 annually less pay when serving in India than if he were serving in Great Britain or in any other part of the British dominions, and every surgeon-captain £50 less by being put upon Indian Medical Service. And now under the new regulation of reducing the salary of the surgeon-major generals any distinguished officer attaining that high position will in future draw less in India than he will if serving in the same position at home. The present rate of pay was fixed in 1780, when it represented at least double the value that it now has. What else can be the reason for this than an overwhelming desire for retrenchment I do not understand. Again, every other branch of the service gets a mess allowance; £100 a year is granted, for example, to the artillery messes, where there will be only three or four officers, and in the military medical messes, where the number averages from 9 to 15, this allowance is withheld. No reason can be assigned for it that I know of. It is only an example of the many disadvantages under which the Medical Services here carry on their duties. The Brigade-Surgeon-Lieutenant-Colonel in India is still denied the extra pay which was long since granted by Royal Warrant, and is withheld with confessed and acknowledged injustice in India without any other reason assigned than that the Government of India objects to make the allowances. The British medical officer serves here a tour of six years, while every other officer serves only five. As regards the charge allowance in dealing with officers of the Army Medical Staff out here, the Government of India has departed from a system under which it pays its Indian medical officers and places the medical officers of the Army Medical Staff in charge of large Station Hospitals, and gives them no extra allowance according to the importance of these charges. Hence I consider it takes one of the strongest incentives to good work from these officers.

CONCLUSION.

Mr. Hart said that he had great pleasure in having had the opportunity of addressing a meeting like that. He hoped in future that these local Branches would be able to take their proper position as intelligent observers and regarding the important branches of the medical profession.

Brigade-Surgeon-Lieutenant-Colonel W. PRICE proposed a hearty vote of thanks to Mr. Hart, which was carried unanimously.

After the meeting Mr. Hart proceeded to the Madras Club, where Surgeon-Major-General Sibthorpe and the officers of the Army Medical Staff and Indian Medical Service entertained him at dinner.

. It has become desirable to publish this address in consequence of the controversial debate which has arisen on the subject of the existing organisation of the medical and sanitary services there in relation to the address of the President

of the Public Medicine Section. At a meeting of the South Indian Branch a resolution was passed describing Mr. Hart's statements as erroneous and defamatory. In respect to the latter complaint, it may be noted that the speaker laid special stress on "the remarkable ability, the enormous power of work, and the excessive overwork of the Indian medical officers; the terrible servitude which enforces on them the attempt to perform a vast amount of duties which cannot be performed." As to the facts which are pronounced erroneous, they will be found more fully stated in the address here printed, which was delivered before the same Branch in India with great acceptance, and which sets out a series of facts which were furnished by the highest authority in Madras, and of which the accuracy is thus far undisputed.

REPORTS

ON

THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

VII.—LISBURN WORKHOUSE INFIRMARY, CO.

ANTRIM.

DR. MACKENZIE, the medical officer of the workhouse, having kindly undertaken to show us over the infirmary, we turned our steps one morning towards the union, which is a little way from the town. It was market day, and the Board was gathering for the meeting, the guardians standing in groups about the lodge. As Lisburn is the county town, standing in the midst of a thriving district, we were prepared to find a large house, and hoped that it might show some improvement on those recently visited. How far our hopes were realised we leave our readers to judge for themselves. A cultivated garden, and ivy and other creepers growing over the lodge, redeemed the aspect of the building from the usual dreariness.

THE INFIRMARY

forms, as usual, the third block of the plan, and has a capacity for 100 beds, exclusive of the fever block. It is a two-storeyed block, but the ground floor is disused; there is an average of 60 patients. Most of these are chronic patients, as the County Infirmary takes the acute and operation cases. The women are in four wards, having a total of 40 beds; one of these is a long ward in which young children are placed, as well as the adult sick and infirm. The other wards are smaller; that for the lying-in women being in communication with the long ward. The men's wards are smaller; there were 22 patients in three wards. The surgery and nurses' room are on the ground and first floors. The infirmary stands east and west; the windows face each other, and ventilation is by means of the upper half of the window, which falls inwards on toothed bar. The walls are plastered and white-washed, roof pitched and plastered, the fireplaces very old and wasteful, and can hardly suffice to warm the wards in severe weather. The bedsteads are narrow iron frames, with straw tick and pillow, resting against the wall, as there is no head to the bed; there are a few tables between the beds, and a few arm chairs and benches. The floors throughout are boarded, and we saw some pictures on the walls. There are no screens to secure privacy, and the beds are too crowded for the cubic space. From the appearance of the wards we should imagine that it was the intention of the builder to provide space for a single line of beds, but that pressure on the accommodation had doubled in number.

THE NURSING

is in the hands of a head nurse who has been trained by Dr. Mackenzie; she has an assistant, and there is a night nurse. The paupers who work in the wards are supposed to be kept to scrubbing and cleaning, but as the number of patients is quite beyond that which two nurses can possibly attend to, we conclude that either the work is left undone, or that the

paupers are pressed into the service. Several patients were in bed; there was a sad case of cancer of the jaw in a male, which required careful dressing to keep it in a wholesome condition; one of strumous disease of the arm, and the rest appeared to be old age, paralysis, and infirmity. A bed card stating name, age, sex, and disease is hung by a string over each bed.

ON THE LANDING

outside, and in close proximity to the wards, there are water-closets, one on each side, but these from some cause were a great failure as sanitary appliances; the flush was inadequate, the pan encrusted with filth, and the odour powerful. These small enclosures serve also as cupboards for pails and brooms, which were mixed up with bedpans, etc., and among this heterogeneous lumber was a painful of pieces of bread. We understand that these places are condemned, and it is time, for such ill-ventilated closets are a standing offence to sanitation. The privies outside are also condemned; those into which we looked were in a most insanitary condition; soil and moisture over the floor and fittings, and no attempt at keeping the miserable structure in even an outward state of cleanliness.

THE LUNATICS,

whose department is under the roof of the infirmary, are housed on the male side in a lean-to addition to the cells, forming a corridor, in which their beds are placed head to foot along the outside wall. Stone-paved floor, whitewashed walls, small windows, bad fireplaces, crowded quarters. Is it possible to imagine any place more unfit for the occupation and treatment of this unhappy class? The cells are rarely used, and Dr. Mackenzie was urging the Board to convert one of these into a padded room. We saw one cell tenanted by a pauper who had been drinking. The head nurse is held responsible for the lunatics; among the males her assistant is a lunatic, in whose care they are left at night, with occasional visits from the night nurse. The females are better lodged; the lean-to corridor is not used for sleeping quarters, the beds being placed in a dormitory better lighted and better ventilated; the cells are only occasionally made use of for unruly patients. The epileptics and imbeciles are kept here with the lunatics. This ward is stone paved. One woman was in charge of a special attendant. The airing courts are square, shingled, enclosed spaces off the infirmary and the lunatic wards. The doctor is trying to induce the Board to erect sheds and seats in these courts, for no day rooms are attached to these blocks.

THE FEVER HOSPITAL,

a detached two-storeyed building of more modern construction, was in use at the time of our visit, two male and two female patients being under treatment. On the ground floor are two wards on each side of the middle staircase, and on the first floor a long ward in each wing, the lower wards only being occupied by the above-mentioned patients, cases of fever. The long wards have not been used since the last cases of small-pox were nursed in them. One nurse is in charge of this block, with pauper assistance. The hospital is self-contained, having kitchen, laundry, and nurse's quarters. The sanitary appliances in this department are of modern construction and well flushed, with provision for cross ventilation, but there is no intercepting lobby, and with all the windows shut—as they were when we went in—the place was quite foul. (Was this shutting of the windows the work of the pauper helps?)

THE NURSERY

is as usual in the body of the house, forming part of the able-bodied women's quarters. It is a stone-paved room, with a rolled-in grate, a small window, dirty whitewashed walls, and open rafters; but for the presence of the four infants and their wooden cradles and their pauper attendants we should have taken it for a stable or a barn. There was no nursery apparatus, such as bath or washing-stand, and the poor children did not appear to be very wholesome; the awful wall of discomfort was the only apparent sign of child life. These hapless infants sleep in the dormitory above with their mothers, on straw ticks laid on the floor. From the nursery we went to see

THE AGED MEN AND WOMEN,

and for these poor creatures we found no better provision for either cleanliness or comfort. The dormitories, one in each wing, are like that of the nursery, except that the floor is raised about 6 inches on either side of the ward, leaving the middle pathway of stone pavement on a lower level. The day rooms also are flagged. There is a window at either end of these long wards; the walls are rough surface, colourwashed, the rafters open, rows of harrow beds and straw ticks against the walls, one old fireplace, quite insufficient to warm a long, narrow room in winter, no artificial light during the night, benches for the poor old people to sit on. We saw a group of wretched women listless and inert in the ward. It is a

LIVING DEATH

for the old men and women in an Irish workhouse. The conveniences for night are the open buckets and pails with which we are now familiar. The ventilation, by means of the two windows, is quite insufficient even in fine weather; in the winter and at night there must be practically none, for the poor fireplace would not give off sufficient heat to allow of open windows.

THE KITCHEN AND LAUNDRY

are both behind the times; in the former are two large boilers, heated by steam, so that all food must be cooked by boiling only; the latter is small and crowded, though we were glad to see some machinery, such as mangle and wringer, for the proper handling of the clothing. The "feeding troughs" are used for serving the Indian meal and milk that forms the midday meal of the inmates in the body of the house. In the infirmary there is a serviceable range, and the cooking is supervised by the nurse. This range also heats the water for the wards.

THE SEWAGE

from the infirmary and the fever hospital is carried into the town system, that from the body of the house drains into cesspools. There are no baths, but we were given to understand that the whole of the water and sanitary system is to be remodelled. We trust that the alterations will include indoor conveniences for the aged and infirm, and baths for the infants.

RECOMMENDATIONS.

Desiring to ascertain whether the sick poor in Irish hospitals are treated on the same lines as those in a workhouse infirmary, we visited the County Infirmary in Lisburn, and were pleased to find that in appointments and management it was on a level with some of our small country hospitals on this side the water. We would therefore ask the guardians of the Lisburn Union to follow our example, and study in the hospital of their own town what should be the treatment of the sick and infirm. The necessary improvements would include a wooden dado round the walls, improved fireplaces, new bedsteads and mattresses, a reduced number of beds to each ward, and the provision of comfortable chairs for the infirmary patients. The whole system, in so far as it affects the aged, the lunatics, and the infants, requires humanising, and the wants of each class need to be considered and provided for, for at present these three classes appear to have been overlooked.

A RESIDENT MEDICAL OFFICER FOR THE BRADFORD WORKHOUSE.

This Board has passed a resolution to appoint a resident medical officer. From the discussion it appears that there are sometimes over 1,000 inmates in the house, of whom over 300 are in the infirmary, so that the Board is taking a right step in thus securing adequate medical attendance for this large number of inmates. The details have yet to be settled, but the principle is agreed to, and is the mover and the seconder passed a well deserved tribute of praise to the good work done by Dr. Proctor, who had held the appointment for many years.

BRADFORD MEDICAL OFFICER.

WE HAVE received the following communication from the Board of Guardians of the Bradford Workhouse, forwarded at the meeting held October 26th. "That we, the guardians of the Bradford Workhouse, have read a report from a commissioner of the BRADFORD MEDICAL JOURNAL relative to the state of this workhouse, and that the report is exaggerated, and we have since the said Government Board Inspector, or any other capable person to inspect the workhouse, as we know that the house is better than and comfortable, and that the inmates are com-

fortable, as reported by a committee who visited the workhouse on October 18th. We also wish to state that we are waiting for a report from the Local Government Board, when we will have the changes according to the Local Government Board's specification carried out, both as regards the sanitary and the sanitary arrangements of the house. We tender our thanks to the Board for its courtesy in sending us a copy of the resolution, and we await the result of the invited inspection with curiosity and eagerness.

WELL-VACCINATED LOCALITIES.

Dr. W. SCOTT TEBB (Bournemouth) writes: I am afraid I cannot agree with the statement contained in your issue of September 21st, that the towns which have suffered most from small-pox epidemics are those known as the woollen districts, namely, Bradford, Keighley, Dewsbury, Leicester, etc.

From a number of medical officers' reports, and also from the columns of the BRITISH MEDICAL JOURNAL, I have been able to ascertain the towns which in recent years have had the heaviest incidence of small-pox. The following table gives the ten towns which presented the highest small-pox attack-rates. In the case of Dewsbury, not happening to have the medical officer's report, I have taken the figures from the Registrar General's returns; and, for the sake of comparison, at the end of the table I have given the statistics for Keighley and Leicester:—

Small-pox Epidemics.	Population.	Attacks.	Attack rate per million.	Deaths.	Death-rate per million.
1. Willenhall 1894	17,684	642	47,013	47	2,696
2. Sheffield 1897-8	323,700	7,400	20,500	670	2,177
3. Walsall 1893-4	74,000	948	12,819	63	1,121
4. Warrington 1892-3	51,000	674	12,481	65	1,264
5. Brighouse 1892-3	25,000	350	6,084	18	882
6. Dewsbury 1891-3	140,000	1,100	7,857	132	911
7. Bradford 1891-4	400,000	3,197	6,981	248	610
8. Leicester 1892-3	84,000	513	6,107	44	523
9. Oldham 1892-4	120,000	800	4,807	102	748
10. Bradford 1892-3	250,000	900	4,378	101	474
Keighley 1891	32,070	72	2,245	7	218
Leicester 1891-4	184,547	265	1,434	21	112

To estimate the amount of vaccination in the population, I have taken out the proportion of attacks vaccinated from the medical officers' reports, subtracting doubtful cases of vaccination from the total attacks before calculating the percentages. The figures are shown in the following table:

Small-pox Epidemics.	Attacks.	Vaccinated of Attacks.	Percentage of Attacks Vaccinated.
Warrington, 1892-3	674	601	89.1
Willenhall, 1894	642	709	89.0
Brighouse, 1892-3	350	2,616	89.8
Sheffield, 1897-8	7,400	5,691	89.3
Walsall, 1893-4	948	426	88.8
Bradford, 1891-4	3,197	704	78.3
Brighouse, 1892-3	140	110	78.3
Walsall, 1893-4	920	667	74.1
Oldham, 1892-4	105	117	70.9
Leicester, 1892-3	513	192	55.6
Keighley, 1891	72	81	45.0

If it be maintained that in an epidemic the proportion of the population vaccinated is lower than the proportion of the attacks vaccinated, we are confronted with the proposition that small-pox picks out the vaccinated; if, on the other hand, you say that the proportion of the population vaccinated is higher than the proportion of attacks vaccinated, then it follows that the inhabitants of Birmingham, Warrington, Sheffield, and Willenhall were almost every one of them protected, which is a very grave reflection on vaccination.

On the whole, I think we may take these statistics as a fairly approximate estimate of the vaccination of the population, especially as they are corroborated by other experience.

Thus, in Warrington my table gives 89.1 per cent. of attacks vaccinated, and in the medical officer's report I find that at the time of the epidemic an examination of 7,522 school children revealed the fact that 7,135, or 94.8 per cent., were vaccinated; now, bearing in mind that school children would probably be slightly better vaccinated than the general population, there is very little difference between the two estimates. Likewise in the Sheffield epidemic the proportion of attacks vaccinated comes to 88.3 per cent.; it is known that for a large number of years over 80 per cent. of the births had been vaccinated, and in 1862, at an inspection of the borough school children, 86 or 87 per cent. were found in that state; therefore at the time of the epidemic the probability is that 88.3 per cent. will not be very far out as an estimate of the proportion of the population vaccinated.

Now let us take the towns in the order of their vaccination, as estimated by the percentage of attacks vaccinated:

Warrington, Willenhall, Birmingham, Sheffield, and Halifax come out the highest with 89.1, 89.0, 88.8, 83.3, and 82.8 per cent. of the attacks vaccinated respectively; as regards small-pox incidence, they occupy the first, second, fourth, seventh, and eighth places on the list in my first table. Next come Bradford, Brighouse, Walsall, and Oldham, with 78.3, 75.3, 74.1, and 70.9 per cent. of attacks vaccinated; these towns are worse vaccinated and have less small-pox, occupying the third, fifth, ninth, and tenth places on my list.

I have no data for Dewsbury except the returns of the Local Government Board, which refer to a district fairly corresponding with that of the Registrar-General's Reports. Thus for the six years 1886-91 an average of 50.9 per cent. of the births were vaccinated, which is lower than Bradford with 68.5, but nothing like so low as Leicester with 5.3 per cent., or Keighley with 8.3 per cent.

Leicester and Keighley had respectively 55.6 per cent. and 43 per cent. of the attacks vaccinated. These are the lowest percentages in my table. Such being the case, the question is, Did small-pox run riot in these towns? My table proves the contrary; thus Birmingham had 3 times and Warrington 6 times the attack-rate of either; Sheffield had 11 times the attack-rate of Leicester, and 10 times the attack-rate of Keighley; while Willenhall had 25 times the attack-rate of Leicester, and 20 times that of Keighley.

Thus I maintain that such towns as Birmingham, Warrington, Sheffield, and Willenhall, where over 80 per cent. of the population is vaccinated, had a very heavy incidence of small-pox; while Leicester and Keighley, where, roughly speaking, only about half the population is vaccinated, had in comparison with well-vaccinated districts very trivial epidemics.

"* We willingly give space to the letter which Dr. Tebb has written to us on the subject of "Well-vaccinated Localities," inasmuch as it is typical of the fallacies into which the anti-vaccinator is apt to fall in dealing with a matter which has nothing of help for him when put forth in plain and unvarnished statements. The antivaccinator never seems able to deal with the question of vaccination in relation to small-pox except by side issues, which remind one of the well-known simile of a herring drawn across the track. The one point on which vaccination takes its stand as a useful and necessary prophylactic is that it can be shown by plain matter-of-fact statistics to have saved thousands of lives, which but for its preventive power, would, humanly speaking, have been sacrificed to small-pox. We have dealt with this main subject at length in the columns of the BRITISH MEDICAL JOURNAL of March 2nd of the present year, and in succeeding numbers. We therefore do not propose to treat of the matter *de novo*, but only so far as Dr. Tebb's letter calls for comment on certain of the ground already gone over.

Dr. Tebb holds that it is not right to state that the woollen districts have suffered most from small-pox, or that well vaccinated towns have been most free from the scourge, and he quotes figures to demonstrate his argument; but prior to the receipt of this letter we had already stated in our issue of October 19th that "it is unvaccinated and badly vaccinated sections of communities (rather than whole populations, which are variously circumstanced as to vaccination) that

¹ In Keighley the Local Government Board returns refer to districts with a population double the size of that dealt with in the report of the medical officer of health.

suffer most from small-pox." We shall deal with this point further; but for the rest we are quite prepared to admit that well-vaccinated towns are at times affected seriously by small-pox, though this most largely in proportion to their unvaccinated sections.

Now, Dr. Tebb is contending that the proportion of vaccinated sufferers in a small-pox epidemic is a criterion of the proportion of vaccinated individuals in the community generally. This is an erroneous assumption. He would have us think that Leicester has, on this basis, 55.6 of its population vaccinated, and this proportion only. The assumption is absurd. We have the word of the medical officer of health that at the time of the recent epidemic of 1892-93 the percentage of persons vaccinated in that borough was as high as 98. Again, Dr. Tebb puts Sheffield as having only 83.3 per cent. vaccinated at the time of the great epidemic of 1857-58, whereas a little trouble in the shape of reference would have told him that an enumerated census of the town *quid* vaccination showed that 97.9 per cent. of the population were vaccinated. We take these merely as samples of the data which Dr. Tebb is putting forward.

According to his argument, we are here stating the case against ourselves, since if the proportion of vaccinated persons be higher than the proportion of vaccinated sufferers by small-pox, then that "is a very grave reflection on vaccination," because most of the people are protected. But is it so? Most assuredly not. Taking the set of towns finding place on page 487 of the BRITISH MEDICAL JOURNAL of March 2nd, 1895, we have totalled the attacks according as they occurred in children under and in persons over 10 years of age. The results show that the attacks in vaccinated children under 10 years of age (474) were only 41 per cent. of the total attacks at those ages (1,154). And were the deaths in like proportion? The deaths among the vaccinated children (8) were as low as 3.5 per cent. of the total deaths at those ages. In other words, the deaths (222) in unvaccinated children were more than nineteen times more numerous in proportion to cases than those in primarily protected children, all classes of vaccination being taken as representing "protection." For we see of the actual mortality in these two classes that, whereas the rate per cent. of cases in vaccinated children taking small-pox was (474 cases, 8 deaths) 1.7, it was in the unvaccinated (680 cases, 222 deaths) as high as 32.6 per cent.

But what of ages over 10 years, wherein it is admitted primary vaccination loses some of its protective influence, the more so as life advances? This, that in the same towns, the total of vaccinated attacks was 6,961, as compared with only 628 unvaccinated patients. The former was, therefore, 92 per cent. of the latter. Were the deaths in like proportion? Not so; the deaths in vaccinated persons (320) were only 55 per cent. of the total (582). But how about the actual proportion of deaths to cases in the two classes? The facts show that in vaccinated patients the deaths (320 in 6,961 cases) were 4.6 per cent., and that in unvaccinated sufferers (282 deaths in 628 cases) the percentage was 44.7, that is, it was 9 times greater in proportion among the unvaccinated.

Now let us look at samples of the towns of which Dr. Tebb treats in other directions. Taking first Sheffield, we know that at the time of the 1857-58 epidemic there were 97.9 persons in every 100 of population vaccinated; but whilst only 88 per cent. of the attacks were in these persons (March, 1857, to February, 1858) the proportion of deaths in this class was not even half that ratio, being, indeed, only 42 per cent. On consideration of the first ten years of life, we see that in the last decennial period for which returns of vaccination officers are issued, namely, 1882-91, as many as 95 out of every 100 children were vaccinated in Sheffield, but that neither the vaccinated children suffering from small-pox, or dying of that disease, were in like proportion to total cases and deaths. Far from it; for whilst the attacks in vaccinated children were only 61 per cent. of both classes, the deaths in these protected children were no more than 3 per cent. of the total mortality in the first ten years of life.

Looking at Leicester, one of the strongholds of the anti-vaccinator, in much the same way, we find that its 88 per cent. of vaccinated population in the epidemic of 1892-93 suffered attack to the extent only of 55 per cent. of the total attacks; and that the mortality was in the vaccinated only

5 per cent. of the total. In respect of ages under 10 years, the facts show that, of the children born during 1883-91, there have escaped on an average 68 per cent. yearly as regards vaccination; but the proportion of attacks and deaths among the unvaccinated sufferers by small-pox do not tally with that ratio. Again—far otherwise; for the attacks were in the unvaccinated to the extent of 99 per cent., and the deaths to the extent of 100 per cent.

We need not go deeper into the matter. Only one word in conclusion. It may be—indeed, it often is—matter for surprise that so many vaccinated persons contract small-pox, that is, once-vaccinated persons. We deplore that the data show this to be the case. But the explanation is not far to seek. There is vaccination and vaccination; and it is the sort of vaccination that has for its corollary in the early years of life an attack of small-pox that is such a discredit to the use of the prophylactic. This sort of vaccination is not worthy of the name, and is commonly performed by incompetent persons or by persons who pander to the increased demand for the fulfilment of the letter of the Vaccination Acts rather than the spirit of those laws. One mark and otherwise inefficient vaccination, which is so increasingly in vogue, this it is which brings discredit on vaccination, and leads to much of the small-pox which is to-day in our midst. So long as the State rules and regulations are not binding on private medical practitioners, so long will vaccinated persons continue to contract small-pox. Not until every person in our country is required to be properly vaccinated, and at the right time also properly revaccinated, can we hope to see small-pox banished from our populations.

SHELLFISH AND WATERBORNE DISEASE.

At the opening of the winter session of the Hull Scientific and Naturalists' Club, held on October 31st, Mr. HOLLINGWORTH, the President, delivered his presidential address on the Artificial Cultivation of Edible Molluscs. He said that in recent years the natural supply had fallen short of the demand, and artificial cultivation of those shellfish most consumed have been resorted to. He then dealt with the mode of cultivation adopted in the case of oysters, mussels, and cockles, showing how liable these were to contamination by sewage matter when laid down in proximity to towns, harbours, and river mouths. In this connection he showed how the conveyance over their beds of sewage matter containing germs of cholera and typhoid was capable of being a source of grave public danger. Basing his argument upon the Government reports of the cholera outbreaks in England in 1892 and 1893, he showed that, whilst in 1892 35 cases were imported into British ports, in every case the local sanitary precautions were sufficient to prevent any extension of the disease beyond those importing it, and that in 1893 13 cases were imported, with no extension in 11 cases. But in that year cholera broke out in 50 separate localities, attacking 287 persons, of whom 135 died; and out of these 50 localities, in 42 only single cases occurred, a circumstance hitherto unprecedented in the history of cholera, and pointing to special modes of infection. Of these cases, 40 per cent. had eaten or handled shellfish within twenty-four hours of being attacked, and in most cases that shellfish had come from the Grimsby and Cleethorpes beds. All the cases (except the imported ones) occurred after the middle of August; that was subsequent to the date when cholera was known to have been imported into Grimsby. He next showed on maps the relative position of the oyster, mussel and cockle beds, and the different sewage outfalls at Grimsby and Cleethorpes, pointing out how easy was the presumption that infection of these beds by sewage matter was not impossible. He pointed out, too, what he considered a dangerous practice, namely, that of placing oysters and other fish in fish docks and near sewer outfalls, as occurs in many places, in order to "fatten" them for the market. In this way he accounted for several outbreaks of typhoid in different parts of the country, details of which he gave. Fish, being the natural scavengers of our coast, would be, he believed, more commonly a source of infection to consumers if they were not rendered innocuous by the process of cooking; but in the case of oysters, which were usually, and of mussels,

which were commonly, eaten raw, this did not obtain. Mr. Hollingworth closed by urging the great importance to local authorities of taking steps to prevent any infection of local food industries.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on October 25th. There were present: Dr. de Havilland Hall, Chairman; Dr. G. E. Herman and Mr. H. H. Crutten, the Treasurers; Dr. J. Pickett, Mr. J. Brinley James, Dr. Major Greenwood, Dr. W. Knowles Sibley, Dr. Walter Smith, Mr. Edward Bartlett, Dr. F. J. Allan, Mr. F. Swinford Edwards and Dr. J. B. Ball.

The audited accounts for the three months ending September 30th, 1895, were presented, and showed that the business was progressing prosperously and on the soundest lines, and the Secretary reported that an unusually large number of applications for the papers of the Society had been received during the previous month.

As usual, the Committee were mainly occupied in the examination and discussion of the sickness claims. The Society is now in its twelfth year of working, and the original members are for the most part reaching the time of life when illness is apt to be severe. So far the sickness experienced has been well within the amount anticipated and provided for in the tables of premiums, but the amount paid for sickness claims is growing and must be expected to grow for some years to come. Not only does the number of claims get larger each year but the severity of the illnesses causing them and the duration of the periods for which the members are incapacitated also show a tendency to increase.

During the last financial year more than one-third of the sickness claims were caused by influenza. During the last quarter very few have arisen from this cause, but several notices of influenza claims have been received in the last few weeks, and it is feared that a large number of them will have to be met during the coming winter.

Prospectuses and all particulars may be obtained from Mr. F. Addiscott, Secretary, Medical Assurance Society, 33, Chancery Lane, London, W.C.

ROYAL COLLEGE OF PHYSICIANS.

THE ordinary quarterly comitia of the Fellows was held on Thursday, October 31st, Sir J. RUSSELL REYNOLDS, Bart., President, in the chair.

THE PRESIDENT announced that Dr. Hale White had been appointed Croonian Lecturer for 1897, in place of Dr. Greenfield, who had resigned through ill-health.

On behalf of Sir Richard Quain, the TREASURER asked permission for the meetings of the General Medical Council, owing to alterations to their own premises not being completed, to be held in the College for one week commencing from November 25th, and it was unanimously agreed to. On twelve previous occasions a similar request had been made and granted.

Messrs. J. H. Dauber, M.B., M. S. Lowenthal, M.D., E. S. Smith, M.D., and H. C. Thomson, M.D., were admitted Members of the College.

The licence was granted to 126 gentlemen, of whom all but two presented themselves under the regulations of the Conjoint Board.

Two communications were received from the Colonial Office, the first enclosing a report upon the recent epidemic of plague at Hong Kong, the second enclosing a powder used by a Chinaman in Java as a secret remedy against diphtheria, and inviting an expression of opinion from the College in respect of it: it was decided that the College could not have anything to do with a secret remedy. A communication was also received from the University of Edinburgh announcing the award of the Marchison Scholarship to Mr. Neil MacVicar, M.B., C.M., and one from Mr. Edgar Willett thanking the College for the loan of preparations to the British Medical Association. A letter was received from Mrs. Blenkins offering a collection of pathological preparations made by her

late husband, mostly during the Crimean war and the Canadian rebellions, and the matter was referred to the Curators of the Museum. The late Mr. George Blenkins, who at the time of his death was Inspector-General of Hospitals, was for many years surgeon to the Grenadier Guards, and in the year 1851 he received the thanks of the College accompanied by a purse of £50 and a cup value £20 for his labours in completely renovating the College Museum. A letter was also received from the Secretary of the Cambridge Antiquarian Society announcing that they were about to publish an illustrated catalogue of plate and other antiquities, and asking permission to take a photograph of the caduceus and cushion presented to the College by Dr. Caius, and of the portrait of Sir William Browne, and it was decided to grant the permission asked.

THE TREASURER reported the fact that he had attended the preliminary funeral of M. Pasteur as the representative of the College, and that no other medical corporation in England had been represented at it.

The annual balance sheet was received and adopted.

The quarterly reports of the Finance Committee and of the Examiners for the Licence were received and adopted.

Reports from the Committee of Management and from the Laboratories Committee were received and adopted, and Dr. Ord was re-elected to represent the College on the former and Dr. Pye-Smith on the latter.

A list of books presented during the past quarter was laid on the table, and the thanks of the College returned to the donors.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING.

THE annual meeting of Fellows and Members was held on Thursday afternoon at the College, Lincoln's Inn Fields, Mr. CHRISTOPHER HEATH, President, in the chair.

THE PRESIDENT, in placing before the meeting the report of the Council for the year ending July 11th, 1895, said that it was his duty and pleasure in the name of the Council to welcome the Fellows and Members to the meeting, and to remind them that they were the corporation of the College. That was a fact which was very often overlooked. The report included the business transacted by the Council of the College between July 12th, 1894, and July 11th, 1895; and therefore, although there was mention of a deputation of Fellows which took place on June 10th, there was none of the Members' deputation which took place on July 26th. On that subject he would merely say that the Council appointed a committee to receive those deputations, and to report to the Council upon the matters brought before them. Owing to various circumstances it was impossible to bring that report up to the October meeting of Council, but it would be brought up next week to the November meeting.

Dr. JOHN INCE, M.R.C.S., then moved:

That the Fellows and Members, here assembled in annual meeting, desire to thank the Council for the interesting and important report now presented; and particularly their approval of the new By-laws, Sections iv and xvi, and of the Regulations of the Council, Section xxv, relating to the meetings of the Fellows and Members of the College.

He said he owed an apology for appearing again with a motion of that nature. It was the third time he had done so, and he trusted it would be the last, because it should be moved by a Fellow rather than by a Member. The motion was desirable, and indeed necessary, for three reasons: first, the President deserved thanks; secondly, it furnished a *locus standi* for discussing the various points contained in the presented report; and, thirdly, it must be remembered that as yet annual meetings were held solely by the favour of the President and Council. They were not statutory, either by the charter or by any by-law; they were convened and conducted, not by by-laws, but by revocable regulations of the Council, and they depended entirely upon the good behaviour of the Members. He hoped that before long the annual meetings would be expressly and permanently recognised by at least a new by-law. Dr. Ince was proceeding to discuss the question of the post graduate course when he was reminded by the President that the report contained nothing on that subject.

Mr. GANT seconded the motion.

Mr. GEORGE BROWN said he did not see how the motion could be accepted. He was sure that the Council needed no thanks from the Members for what they had done in connection with the College. He moved the previous question.

Mr. BRINDLEY JAMES seconded the amendment, which, on being put to the meeting, was carried by 17 votes to 5.

Mr. JOSEPH SMITH, M.R.C.S., then moved :

That this meeting requests the Council to take steps to obtain an amended charter, which shall contain the following provisions: (a) That no alteration in the constitution and external relations of the College shall be effected without the consent of the body corporate, convened to discuss such alterations. (b) That the present annual general meeting be made statutory, and that the report of the Council shall be submitted for formal adoption. (c) That the number of the Council be increased to thirty-two, and that eight of these, who may be Members, shall be elected by the Members only, provided always that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council.

He said it had frequently been asked by members of the Council, "Who are these men who are agitating for this reform of the College? What are their numbers? Are they men of any importance?" Such members must know perfectly well that for the last ten years resolutions asking for reforms in the constitution of the College had been carried by crowded meetings of men from all parts of England, who had come up at great cost and risk to support the very resolutions which the meeting was now asked to sanction. And yet there were members of Council and Fellows who were continually throwing in the eyes of their fellow members the eternally old tale that this agitation was only carried on by an insignificant few. When he went before the Committee the President asked, "What are the numbers of your Association?" His reply was that it did not matter whether the Association numbered 5 or 5,000; they spoke in the name of those men who had met in that room for years, and also in the name of the 5,000 men whose names were attached to petitions at present lying in the Home Office, asking for the very reforms which were now sought. With regard to the first clause of the resolution, the intention was that no alteration in the constitution and external relations of the College should be legal without the consent of the body corporate, so that the Council would not be able to exclude the Apothecaries' Hall or deal with matters of that sort without the consent of the Fellows and Members. Mr. Smith was proceeding to discuss the next provision, when

The President suggested that the paragraphs should be taken separately.

Mr. DICKINSON, in seconding Clause 1, said the old charter showed that Members had some inherent rights beyond those of entering the library, attending lectures and using the common room. The Charter of 1800, which was obtained under somewhat doubtful circumstances, the object being very largely to exclude the Members from all share in the government of the College, clearly stated that the Fellows and Members were one body corporate and politic; that they had a perpetual succession under a common seal; that in any legal action taken by or against the College the Members were all implicated; and that the building belonged to the Members absolutely from cellar to roof, together with all other property held by the College. In the face of these facts was the continued exclusion of Members from all share in the election of the Council either just or generous? Communities of that kind, whether called brotherhoods, guilds, or corporations, had existed for centuries, and were just as necessary now as ever. Such guilds contained three leading features—their members were all equal before the guild; every member was entitled to the support of the brotherhood in any quarrel which they considered to be just; and they had an equal share in the jurisdiction, which meant administration. The Members of the College of Surgeons, on the contrary, were not equal; there was a superior order of members who exercised all their inherent rights; they got no support from the College in any disputes or difficulties with outsiders, and there was no share either in jurisdiction or administration. These things ought not to be. The only real objection to their claim which they had been able to extract from the Council was that they did not consider it desirable to diminish the privileges of Fellows by

depriving them of the exclusive right to elect and constitute the Council. To this he replied that the Fellows as such had not by the Charter any stake in the property of the College, and that it was only as Members that they had any claim upon the Council. It was true that by the Charter of 1813 the Fellows were entitled to the exclusive privilege of electing the Council, and with that privilege he had no wish to interfere. What was proposed was to enlarge the Council, adding representatives from the Members. Surely the Fellows did not think so meanly of the Members as to refuse to sit with them upon the Council of their own College? He did not think so meanly of the Fellows, and was convinced that if they could be satisfied that these reforms would be of benefit to the College as a whole, they would allow no lower motive to influence them.

The resolution was then put and carried *nem. con.*

Mr. JOSEPH SMITH, in proposing the second paragraph, providing that the annual general meetings should be made statutory, and the report of the Council submitted for formal adoption, said it was useless having an annual meeting and a report unless that report could be criticised and amended if not satisfactory. If the meeting had not that power it was perfectly useless for them to come together. The Members were the mainstay of the College, and to a considerable extent the mainstay of the Fellows. They were the body corporate in that respect. At present, as Dr. Ince had said, they held those meetings upon their good behaviour. It was quite within the option of the Council to say: "We will have no more of you, and if you come here we will send for a policeman and send you away," as had been done on a previous occasion.

Mr. DICKINSON seconded the resolution, which was carried with one dissentient.

Mr. JOSEPH SMITH, in moving the third paragraph of the resolution, said that the Members asked that the constitution of the Council should be increased from 24 to 32—that the 24 Fellows should remain, and that the Members should have 8 representatives. There were something like 900 or 1,000 Fellows, who had the power to elect 24 members of council; they, 14,000 or 15,000 Members, asked in the very humblest manner to have the power to elect 8. This was not unfair, seeing that the Members contributed something like £15,000 a year, as against the £1103 which the Fellows contributed. It would be quite impossible for the eight representatives to interfere with the twenty-four, or to endeavour to swamp them. At the present time they had no power over the election of the Council, over the finances, or over internal and external relations; if they had he was quite certain that the fatal mistake of amalgamating with the College of Physicians, leaving the Apothecaries' Hall out, would not have been perpetrated. They all admired the gentlemen who sat on the Council for their surgical attainments, but they did not feel that they could have anything in common with the body of general practitioners; it was quite impossible that they should do so. He remembered the President many years ago—he was then a reformer—asking, would not his position be a grand one if he were elected by the whole body corporate; not, as now, simply by Fellows? The President was the President of the Fellows, and not President of the College of Surgeons *de facto*, although he might be so by law. The Members had lost all interest in the affairs of the College. Was it good, he asked for any body of men to be practically self-elected?

Mr. DICKINSON, in seconding the third paragraph of the resolution, said that the Fellowship was essentially an academic distinction, and was mainly valued by the Fellows as such without reference to their position on the Council. He admitted that from an academic point of view the Fellowship had been a distinct success, but he protested against the continued usurpation by a limited class of members, however superior, of the functions that belonged to the corporation as a whole. The Fellows had had for over fifty years a right to elect a governing body, and it was not proposed now to oust them from their right, but merely to add eight representatives of the 16,000 Members to the Council. Except for obtaining hospital and such-like appointments, the Fellowship was of very little use to anyone in practice. What the public wanted was "M.D." If the College could grant

the degree of M.D. there would be hundreds of applicants for it, and that degree the College ought to have been able to offer a long time ago. He was sure that if Members were added to the Council, those Members would press the matter of M.D. forward.

Dr. INCE and Dr. ALDERSON having spoken, Mr. TIMOTHY HOLMES said the proposal was a very moderate one, and still left to the Fellows the entire government of the College. It was impossible for eight Members to carry their own propositions in any case in which the Fellows were not seriously divided in opinion.

The resolution was then carried with two dissentients.

THE ADMISSION OF WOMEN.

The PRESIDENT stated that the Council desired to afford the Fellows and Members present at the meeting the opportunity of expressing their views upon the question of the admission of women to the examinations for the diploma of Member. The Council had received a letter from Mrs. Garrett Anderson, forwarding a memorial asking that the students of the London School of Medicine for Women should be admitted to the examinations of the College, and enclosing various documents relating to such petition. It was a very important and vital question, and the Council wished to have the benefit of the advice of the meeting upon it before arriving at any decision.

Mr. JOSEPH SMITH asked if the College were bound to follow the lead of the College of Physicians in the matter.

The PRESIDENT said that under present circumstances no man could receive the Membership of the College without at the same time becoming a Licentiate of the College of Physicians. The vote taken a short time before at the College of Physicians had been passed by the Fellows only, but at present the College of Surgeons could not issue their diploma without the concurrence of the College of Physicians, or *vice versa*. That, of course, was an arrangement which was not finality. Any resolution passed by the College of Physicians would not be binding upon the College of Surgeons.

Mr. GEORGE BOWEN said that the fact of the Council asking the opinion of the meeting upon the matter proved that the action of the Members and Fellows in almost unanimously inviting them to apply for a new charter was a wise one. He had not seen any arguments put forward why women should be admitted as Members of that body; he did not believe in the equality of the sexes, and if he had an operation to be performed in which life was in danger, he should hesitate to trust his life in the hands of a woman. In the interests of the public they should not admit women to their body.

Mr. JOSEPH SMITH moved:

That, so many portals being open to women to obtain a surgical diploma, it is not expedient that this College should admit women to the examination for the diploma of Member.

Mr. BRISTLEY JAMES, in seconding the motion, said he felt it would be a very sad day when the Royal College of Surgeons of England, which was the grandest body in the world, should be under petticoat government. If women came into the College of Surgeons, they would want to become Fellows and Examiners, and take a seat on the Council, and if that came to pass, undoubtedly they would be under a certain amount of petticoat government. For himself, he objected to women entering the profession.

Mr. LUCAS said that as a member of the Convocation of the University of London he had watched this question from its inception to the present time. He had heard that staunch Conservative, Sir William Jenner, rise in his place and say, "I have one daughter, and that a very dear daughter, but yet I would rather follow her to her grave than see her entering the medical profession." A great change had come over the profession since then. Women had been admitted first to degrees of the University of London, and afterwards to the Convocation of the University of London, and were now recognized as part of that body. He as an examiner of the University of London had examined those women who had presented themselves for medical degrees during the last four years. He believed, compared with the average medical student, the average medical woman was perhaps below the medical student, but here and there surpassed the ordinary medical student. When there were such

women as those, the College of Surgeons ought not to let any little petty jealousy or fear prevent them from doing those women justice. He hoped that the meeting would not be dragged at the tail of that very conservative body, the College of Physicians, but do justice to the women and admit them. He was no enthusiast in the question, and it was because he was not an enthusiast in favour of medical women that he would do his utmost to give them every chance. If they were admitted to other degrees, why should they be excluded from this degree? It was absurd to suppose that there could be any competition between men and women. If a woman took her diploma she might, perhaps, beat a man, and take a higher position; but, surely, the strength which belonged to his masculinity would put him above any fear that she should come in any way into competition with him. Let women be admitted, let them have the degrees, and all the rights in connection with them; to exclude them would be most unjust and unfair, and it was because he believed it to be both unjust and unfair that he moved the following amendment:

That in the opinion of this meeting women should be admitted to the diplomas of this College.

Dr. BARNES said that surgery, of all other things, was the highest grade of the profession, demanding, as it did, the highest talent, skill and mental and physical powers, and those, he thought, did not belong to women. Women might undertake the inferior grades of obstetrics and gynaecology, but he was of opinion that the Council of the College had been somewhat at fault in opening the door to them, and he maintained that women were not qualified to undertake the higher branches of obstetric medicine in connection with surgery. Surgery belonged to men and strength, and where strength was there the great amount of gentleness lay. It was simply a horrible thing for him to see women operate. They might be gentle in their minds, but they certainly had not the power which was necessary to perform serious surgical operations. He thought it was a degrading thing to admit women to the study of medicine in any branch, and it applied most strongly to surgery.

Mr. NORTON seconded Mr. Lucas's amendment. Most examinations he said were open to women nowadays, and he saw no reason why the College of Surgeons should exclude them, all the more so because that would not prevent them from entering the profession. There must be some private reason if they decided to exclude them from the examination. The point had been raised that they were not prepared to undertake such duties. Women, however, had been ten or twelve years in the profession, and therefore he thought were in a position to undertake such duties. Only perhaps 2 or 3 per cent. of those men who passed the examination of the College of Surgeons became operators, and in the same way, no doubt, comparatively speaking few women would lay themselves out as operating surgeons. Everyone of them without exception would devote themselves entirely to larger operations as was the case with men. The question of rivalry must present itself amongst members of the medical profession, but it was quite a small question, for women Members of the College would mostly be women practising abroad in the Colonies, and in India especially, where they had already done great service as was well known, in undertaking the treatment of women there. Women in India were not allowed to see men, and therefore women must enter the profession if good was to be done in that country where these questions came in.

Dr. ALDERSON admitted that a great change had come over the profession, but that change had not been for the better. What had women done to aid surgery or medicine? He thought the body would not gain by admitting women to its examinations.

On Mr. Lucas's amendment being put, it was declared by the PRESIDENT to be lost, 48 voting for it and 53 against.

Mr. Joseph Smith's original motion was then carried.

A vote of thanks to the President terminated the proceedings.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, NOVEMBER 9TH, 1895.

LUNATICS AT LARGE: A PUBLIC DANGER.

PUBLIC attention has been strongly directed by a recent case to the provisions of the lunacy law under which certain urgent cases may be placed quickly under care and treatment in an asylum, either for their own welfare, or for the safety of the public in relation to the element of urgency; and, in some quarters, opinions have been freely expressed to the effect that such provisions should not be permitted to exist. They were inserted and introduced by the present Lord Chancellor for the public good. In a relatively small number of the cases of indubitable sudden insanity that occur those particular provisions are of the very greatest possible value in the interest of the lunatic's welfare and of the public safety.

So complicated, protracted, and, in some cases difficult, is it to place an insane person under care and treatment by the ordinary provisions of the Act, that a provision for urgent cases is really necessary; and detention under the urgency order is for so short a time, and surrounded by so many precautions as a merely temporary measure, that it merely enables time to be secured for the carrying out of the full ordinary provisions of the Act with all their safeguards of the personal liberty. But it is not on this aspect of the subject that we intend to dwell; and we merely pause to protest against the suggestion that the procedure in placing a lunatic under care should be one similar to that for a criminal conviction in a court of law and its full publicity. What has the unfortunate lunatic done that he should practically be indicted for his disease, and, if found guilty of it, be sentenced in due course, and with full publicity? Why should he be reduced to the position of a criminal on trial?

So far from the certification and detention of lunatics, and even of dangerous ones, being too easy, as is so freely alleged in some quarters, there appear to be greater difficulties in certifying and in detaining in asylums even dangerous lunatics, than public safety requires; and it is from the point of view of public necessity and safety that we refer to some recent occurrences in different parts of the country.

Only a few weeks ago, and since then, we referred to several cases, as, for example, to the case of a lunatic discharged from an asylum who attacked several persons, strangers to him, with dangerous and, in some instances, fatal results. Also to the case of a lunatic woman who causelessly attacked and killed another woman, a perfect stranger to her; and to the case of a lunatic who, seeing a

woman asleep in a public ground, smashed her head in with a hammer. Indeed, it is not pleasant to rub shoulders in a crowd with, or to meet on a lonely road, a homicidal madman armed with some implement such as hammer, spade, axe, or pitchfork.

Recently, at Doncaster, an Irish labourer was charged with attempting to murder three men. The prisoner, while sleeping in a room with seven other men, suddenly appeared to be seized with frenzy, and began stabbing his fellow-lodgers with a large knife. One of them was stabbed in the abdomen, and was afterwards reported as being in a serious state, and likely to die. The prisoner, who has been certified to be insane, made a rambling statement when charged, and was committed for trial at the assizes.

And, again, the other day a postman was indicted for the wilful murder of his infant son. He had been out of work for two years, and the wife went out to earn money by charring, he remaining in charge of the children. On one occasion when she returned husband and child were missing. The dead body of the child was found. The husband pledged some clothes for four shillings on that day, and came to London. He was arrested, and practically admitted what he had done. The only question was as to the condition of the prisoner's mind at the time of the murder. Several medical men gave evidence concerning his state of health, and the jury found him guilty, but that he was insane at the time he did the act; and he was ordered to be detained during Her Majesty's pleasure.

Whether or not we have a similar case in the tragedy at Earl's Court, in which a woman of a very retiring and reserved nature, never mixing much with her neighbours, and separated from her husband, first strangled her pretty little girl, aged 4 years, and then hanged herself, certain it is that the public newspapers afford every week abundant evidence that many dangerous lunatics are evidently amongst us, and that on public grounds it is necessary that no undue difficulties should be raised to freeing the public of the danger, and that the separation of dangerous lunatics from their fellows in the general public should be facilitated rather than hampered.

DISEASE AND INSANITY IN PRISONS.

A MORNING contemporary has again launched its wrath against modern prison administration; taking for its object the statistical reports of the Medical Inspector of Prisons, which are stigmatised by our contemporary as "misleading and fallacious." Various figures which appear in those reports are adduced as showing that imprisonment in England causes a higher lunacy rate and mortality than exists amongst the free community. The writer goes on to say that Dr. Bridges, a member of the recent Committee of Inquiry into prison management, "will have nothing to do" with such misleading comparisons.

Criticism based on a fair and equitable desire to arrive at a better state of things is of course always commendable; but we cannot see the wholesome purpose of the kind of twisted arguments brought to bear by our contemporary. Witness what Dr. Bridges actually said in relation to these prison results as put forward by a writer in the *Fortnightly Review*. Referring to certain figures, intended to show the ill-effects of imprisonment on the mental condition of

prisoners, Dr. Bridges says: "When carefully examined, the inferences drawn by this writer seem not to be justified."

The fallacy of attacking our present system on the strength of mere numerical comparisons with the free community was admitted during the examination of some of the medical witnesses called at that inquiry. The fact is that the sooner we admit that the conditions of mental and bodily health, as deduced from the statistics of a prison population compared with a free population are not at all reliable, the better will be our chance of viewing the matter correctly. A caged bird can never exhibit precisely the same conditions and circumstances as a bird at large; and a man shut up must of necessity, owing to his peculiar environment, show some results quite different from a free man. Thus the imprisoned man will not be run over by a van when drunk, but he may pine for his accustomed intoxicant, and even fall into a condition of delirium tremens for the very want of his habitual stimulus. Thus, here we can conceive a delirium actually consequent upon his imprisonment. But shall we therefore urge that all felons shall have the means of free drinking supplied them? Again, many natures require much amusement and excitement if they are to maintain a high level of mental briskness; but because a man has overdone his search for excitement, and has landed himself within the clutches of the law, are we to say that prisoners shall play at baccarat and have merry-go-rounds to preserve their laughing and rollicking expressions?

The time appears to us to have come when wise men should look upon imprisonment as being an abnormal condition brought about by the abnormal actions of abnormal persons, and as having naturally some abnormal results. Amongst these results we actually find an abnormally small amount of serious illness, no drunkenness, an abnormally small amount of the usual ailments of life, and if we were to see an abnormally large amount of mental unstableness, which we do not admit, it would be no more than the natural consequence of the depressing influence which any punishment must produce on the punished.

As long as mankind in general considers that a breach of law ought to entail punishment, so long must we see some distinct objective results of that punishment, whatever form they may take. If the penal condition is made to entail very arduous work, which is rare now in our prisons, then the body must of necessity show results where a weak point is touched; but if the punishment assume for a generation the phase of solitary confinement, then the mental weak points will be found out, and we get depression of spirits. But for any reasoning person to suppose that the free and the incarcerated are to offer exactly similar statistics of health is on the face of it absurd.

To take the question of insanity. A horde of lowly educated and ill-nourished individuals come under the daily care and notice of a medical man for a certain period of their lives. A certain number are found during this period to be insane. Had these not been in prison they would seldom have been seen by a doctor, and their weak points would seldom have been found out. Prison detects the weak point, and the numbers of the insane appear larger than

amongst the free population. Some, too, of course exhibit the unavoidable results of a mental trial on a weak organism. If the whole population suddenly came under the notice of a body of dentists the proportion of teeth found carious would increase suddenly among the community, but caries would not have resulted from these people being seen by the dentists. Just in the same way it is illogical to say that a prison population is lowered in mental tone because the deficiency comes under constant skilled observation.

It would be puerile to imagine that imprisonment never produces insanity, just as it would be obviously false to say that sudden success and wealth do not at times have the same effect; but anyone scientifically conversant with modern prison matters, and not merely judging from hearsay, is aware that, consistently with some remnant of punishment still being endured, the modern prisoner is, if anything, too well cared for in body and mind. The modern danger is really lest we should lose sight of the fact that imprisonment is meant to be deterrent.

In connection with the subject which suggested these remarks, we cannot help thinking, if one official is to be held responsible for the mental and bodily wellbeing of a nation's criminals, that the largest power and influence ought to be attached to such an office. The influence of the medical inspector should be improved to the extent of his ranking at least as high as a commissioner of prisons, and by his suggestions and recommendations being advanced immediately into the hands of the Secretary of State. It would then be more reasonable for the public to insist upon urgent remedies being promptly applied, when an official directly in contact with the chief of the Home Department had cognisance and responsibility, than as now, when the medical inspector is subordinate to, and merely the servant of, the Commissioners. This very matter is strongly commented upon by Dr. Bridges in his final remarks on the prison system in connection with medical responsibility and official work, and is urged in the body of the report.

THE MORTALITY OF MEDICAL MEN.

SOME little time ago we commented on assurance statistics issuing from Australia which went to show that medical men should be placed among the hazardous lives, their mortality not being much below that of publicans. We have now to call attention to some very impressive and suggestive facts from a paper communicated by Dr. Kortright to the *Brooklyn Medical Journal* on the Mortality and Causes of Death in Medical Men. The paper is based on an analysis of the mortuary records of 450 physicians who lived and died in New York and Brooklyn and the vicinity during the past eight years. The average age of death was 54.6 years and the mortality was 25.53, as compared with a mortality of 15.93 in clergymen and 20.23 in lawyers. The rate of mortality among members of the medical profession was only exceeded by saloon keepers, butchers, quarrymen, and poor factory operatives.

Suicide is four times more common among physicians than among other adult males. Under this head are included many cases of accidental poisoning. This large mortality from the self-administration of powerful drugs should be a warning to medical men of the danger they incur from such a practice. The death-rate from consumption among doctors is about

half the general rate; on the other hand the death-rate from typhoid fever is exceptionally high—4½ per cent. having died from this cause as against an average rate among adult males of 1½ per cent.

One point comes out in a forcible manner from these statistics and that is the high death-rate due to arterial sclerosis and other degenerative changes. The mortality among doctors from these causes was 35 per cent. whereas among all adult males it is only 25 per cent.

There can be but little doubt that these degenerative changes are the outcome of the irregular life led by the average medical man. His meals are taken at all hours of the day, the food is often eaten hurriedly, prolonged abstinence is made up for by a too large meal or an extra amount of alcohol; he is overworked at times, and gets too little sleep. If he is feeling ill and indisposed for work, unlike other men, he cannot easily take a rest, so that he keeps on his weary round long after he is absolutely unfit for either mental or physical exertion.

The practical conclusions that we would deduce from the foregoing are the importance of at least three weeks' complete rest and change during the course of the year; extreme moderation in the use of stimulants, which should only be taken with meals and never as a substitute for food; meals should be taken as far as possible at regular times, and they should not be hurried over. If there is any evidence of commencing failure of health, arrangements should be made to give up night work for a time. Above all things it should be borne in mind that worry does more harm than work, and that by the employment of a little method the daily work of life may be carried on with less friction and mental strain. Should an incapacitating illness occur, the knowledge that his immediate needs will be provided for by an assurance society will be a source of comfort to the patient; hence the desirability of all medical men joining a society such as the Medical Sickness, Annuity, and Life Assurance Society, which provides for weekly pay during incapacity either from sickness or accident. If the patient has others dependent on him, then the fact that in his days of health he took out a life assurance policy will diminish his anxious forebodings as to what will become of those near and dear to him should he be prematurely called away.

REGARDING the decision of the Royal College of Physicians to refuse their licence to women practitioners, the *Yorkshire Daily Post* says that the medical profession is overstocked, and any discussion on the subject must be largely influenced by this consideration. In the *Peeblesshire Advertiser* last week there was actually an advertisement for a parish medical officer at a salary of £6 a year, and it is stated that already the parish council has a choice of several applicants.

THE new French Ministry includes three representatives of the medical profession. M. Berthelot, the Minister for Foreign Affairs, is a member of the Institute and of the Academy of Medicine; he took the M.D. degree in 1865. M. Viger, the Minister of Agriculture, and M. Combes, Minister of Public Instruction, are also Doctors of Medicine. M. Berthelot and Viger have each already formed part of several Ministries. M. Combes, who now for the first time holds a portfolio, is Vice-President of the Senate, in which he sits for the Charente Inférieure.

THE BRITISH MEDICAL BENEVOLENT FUND.

THE appeal from Sir William Broadbent, the Treasurer of the British Medical Benevolent Fund, published at p. 1185, will not, we feel sure, be made without effect to a profession which has always shown itself admirable in its readiness to help its less fortunate members. The stories of misfortune, often very little deserved, which come before the Committee are in many instances of the saddest possible nature.

THE HUXLEY MEMORIAL.

WE learn from our Transatlantic contemporary *Science* that an American Committee is being organised to act in concert with the English Huxley Memorial Committee. The latest reports from Professor Howe indicate that practically all the American men of science who have been approached have signified their willingness to serve. The biologists in particular are likely to be well represented, and the leaders in every field of scientific work will co-operate. It is hoped and anticipated that the contributions from the United States will rival those of Great Britain.

A FORGOTTEN MEMORIAL.

AT the last meeting of the College of Physicians it was mentioned that a brass tablet was about to be erected in the College library commemorating the services to the College of Sir Henry Hallford, who was President for twenty-four years. A resolution to this effect was passed in 1844, but has for some unaccountable reason been overlooked. It is, however, never too late to mend, and arrangements are being made to erect the tablet over the central fireplace and immediately under the portrait of Harvey. When it is remembered that it was entirely owing to Sir Henry Hallford that the College secured their present premises, the remissness of the Fellows fifty years ago seems unaccountable.

CYCLE AMBULANCES.

THE use of ambulances mounted on cycle wheels and driven by one or more cyclists appears likely to extend. The city of Birmingham was presented with a cycle ambulance some months ago. In this pattern a frame carrying a hooded detachable stretcher is supported on two bicycles, which could each be ridden by a cyclist. We now learn that a German surgeon, Dr. Hoenig, has designed an apparatus which he calls a cyclo-ambulance. It consists of a car covered in with canvas, which contains a folding litter, and rests on four side wheels, and a fifth wheel in front pedalled by a cyclist. A seat and pedals are also provided at the back for another cyclist. The top part of the car can be lifted off, a patient can then be placed on the litter, and the top replaced on the axles. The patient can be watched by the cyclist at the back through a glazed window; but the patient is also provided with means of attracting the attention of the cyclist by using the rubber ball of a cycle horn. An aperture in the side of the car affords access to the patient when he is in need of help. The ambulance is reported to be in experimental use in Berlin, and is easily steered and manipulated.

TRAINING NOT DANGEROUS.

THE death of Mr. Cotton—"Benjy Cotton"—has brought up again the old homilies about the mischief of training and of athletic exercises. These bogies have been dispelled over and over again, but the ordinary man does not seem to get this into his mind. The man in the street hugs the old fallacy that whatsoever happens after any prominent antecedent is a consequence of it. Mr. Cotton is a great oarsman; he dies in early life, therefore his death was due to over-training or over-rowing. The late Dr. Morgan long ago proved up to the hilt that healthy young men, properly

¹ This ambulance was described and figured in the *BRITISH MEDICAL JOURNAL* of April 1894, vol. p. 385.

² *Revue du Cercle Médical.*

trained, seem to stand any manly exercise; and nothing can be less wholesome than to have our young men anxiously balancing this risk and that until they sink together to the level of games like lawn tennis, which bring out no qualities of courage or endurance. Careless as some of our youths often are, they seem to come to little harm, save from loafing and self-indulgence—habits fortunately not yet prevalent among young Englishmen. We can relieve the anxious minds of our daily contemporaries: Mr. Cotton's death had nothing whatever to do with muscular exertion. Here and there a man may suffer in health from unregulated exercise; men are now and then killed in the hunting field; but such an accident in a sound man is too rare an event to spoil our pleasure in seeing the popularity of sports which strengthen both mind and body. Nor are we rebuffed by the awful example adduced by the *Westminster Gazette* of poor Hector Maclean, who, at the height of his physical prowess, "was carried off in a few days by typhoid fever." Sad indeed was the result, but athletics give us no immunity from infectious disease.

THE DANGERS OF THE BARBER'S SHOP.

A CASE was tried the other day in which a man claimed damages from a barber on the ground that he had contracted contagious skin disease in his shop. The legal aspects of this particular case do not concern us, but it is important as directing attention to a source of danger, which, though generally recognised even by the public, is still very insufficiently guarded against. There can be no possible doubt that skin disease is not infrequently communicated by contaminated instruments in shaving and hairdressing even in high-class establishments where the use of proper precautions might reasonably be expected. From time to time, dermatologists in hospitals have the opportunity of seeing what may be called epidemics of "barber's itch" among the patrons of a particular tonsorial artist. The disease communicated is sometimes ringworm, which is the parasitic form of *sycoosis*, or a non-parasitic form due to infection by cocci, and other forms of disgusting, disfiguring, and often painful disease have been known to originate from the same causes. The infective material is probably conveyed, not by the razor, which is well stropped and afterwards dipped in hot water, but by the brush or the sponge. The remedy is clearly that barbers and hairdressers should not be satisfied with mere cleanliness, but should use proper antiseptic precautions in their ministrations. The observance of such precautions is compulsory in certain parts of Germany and in other countries, and when the London County Council has a little time to spare from the purging of the music halls it might with advantage bestow some attention on the physical purification of the barber's shop. In the meantime customers might do something for their own protection, if they were to make a point of keeping their own brush, sponge, etc., in a special cupboard at the establishment which they frequent.

EXIT EUSAPIA!

THE collapse of Eusapia Palladino, one of the chief priestesses of the latter-day occultism, is highly satisfactory to all lovers of truth as the exposure of a particularly impudent system of imposture. The event has a much greater importance, however, as an additional exposure of the facility with which cultivated minds of a certain type can be cozened by clever trickery. It takes little to delude them, because their "suggestibility" (if the word may be allowed) makes themselves active helpers in the process. The maxim *Populus culti decipi* applies to philosophers not less than to the vulgar; they believe because they wish to believe. Nothing can be more amusing to a cynic than to see persons, often of a high order of intelligence, accept the foolish wonders of spirit-rapping and table-turning with a simple faith which they scornfully refuse to more sacred mysteries. For years men skilled in all the learning of schools and trained to

some extent in scientific observation have been sitting at the feet of this illiterate woman, reverently waiting for the stirring of the muddy waters of deception, which they eagerly drink in as manifestations of a "new psychic force." It would be comic if it were not deplorable to picture this sorry Egeria surrounded by men like Professor Sidgwick, Professor Lodge, Mr. F. H. Myers, Mr. Andrew Lang, Dr. Schiaparelli, and Professor Richet solemnly receiving her pinches and kicks, her finger skiddings, her sleight of hand with various articles of furniture as phenomena calling for serious study, if not as direct revelations of the Unseen. It is saddest of all to think of Lombroso, who must know more than most men of human imposture, in this circle of devotees.

Who could not laugh if such a man there be?
Who but must weep if Allicus were he?

The fact is, however, as was pointed out by Mr. Ernest Hart in his article on The Eternal Gullible in the *Century*, men of science are not as such particularly well qualified to judge of matters in which the disturbing influence of the "personal equation" has to be taken into account. They are apt to be misled by starting from the assumption that all persons may be taken, for the purposes of experiment, as equally trustworthy. In studying the phenomena of occultism of any kind, it is essential to bear in mind that there is a twofold source of fallacy—in the facts and in the interpretation thereof. Everything that appears to be inexplicable is not necessarily supernatural. What is wanted before everything else is the detective skill of the expert. Had Mr. Maskelyne not been present at the recent sitting at Cambridge, Eusapia's shrine would probably not have been deserted even now. Indeed, there is Professor Lodge, "of the unfaithful, faithful only he," whose robust faith in the earlier manifestations is still undisturbed. And yet the whole thing is such a transparent fraud! Else why all these jealous precautions, extending to details of dress? Why all this careful darkening of the stage before the performance unless it be because the children of darkness hate the light? Then, what can be more childish, more utterly futile than the manifestations themselves? The silly games at "touch," and the purposeless evolutions of chairs and tables might amuse a child of five at a pantomime, but what is to be said of learned professors and earnest and otherwise intelligent men and women seeking spiritual edification in such foolery? Is any human being likely to be the better or the wiser for the rappings of "John" or the scribblings of "Julia"? With so many serious problems awaiting solution it is not only deplorable but in the highest degree discreditable that minds made for better things should waste their powers in dabbling with what is simply despicable and degrading imposture.

THE SICK POOR IN IRISH WORKHOUSES: LISBURN: "A LIVING DEATH."

OUR Commissioner, in describing the conditions which surround the old and infirm in this workhouse, speaks of their life as being "a living death." We have been much struck in reading the report of this workhouse and of others to note how very little—indeed, we might say nothing—is done to alleviate a lot that is sufficiently hard. The guardians provide four walls and a roof, scanty firing and meagre food, poor clothing, not always either clean or sufficient, and with this provision are satisfied with the good deed done for the aged men and women who come on the rates. If the subject is discussed in the press or in a friendly conversation, the argument is urged that the pauper is at least no worse housed, clothed, or fed than the independent labourer, and we accept the statement, but we must point out that the independent labourer is free to go in and out, to choose his associates, to meet his friends, and to order his life as he pleases. These privileges are valid compensations for the hardships of his lot. His food also may be even more com-

men than that of the pauper, but at least he may vary it if he likes in mode of cooking if not in kind, and the outside world with its interests offers some variety to the monotony of his life. To the pauper the priceless boon of liberty is denied. The long dormitory with its comfortless beds, hard benches, imperfect light, low temperature, white-washed walls, and unchanging inmates, is his prison, the yard is his exercise ground, and the meal of bread with milk or Indian meal and milk is the one excitement of the day. Night brings with it the door locked on the outside, the feeble light of the lamp, enough to show a long row of beds, each with its occupant, some shivering in the chill air of the ward, the foul-smelling buckets, and perhaps the foul-tongued conversation, and this for eleven hours out of the twenty-four, the morning's light only bringing with it the same dreary round—is not this “a living death?” Now what have these paupers done that so severe a punishment should be meted out to them? They have by their labour contributed to the national wealth, but they have no wealth of their own to keep them in old age, and why? Wages were low, or sickness set in, or economic changes altered the state of the labour market, or a large family absorbed the family income, or drink and improvident habits brought the man down, but none of these reasons are crimes against society. We maintain that the pauper has a right to just so much freedom and consideration as shall be possible in community life. Moreover, we would urge that the man who by his labour has added to the wealth of the nation has a claim on that nation which is not met by providing him with four walls and a roof, and the doling out of such meagre necessities as suffice to keep body and soul together. Guardians in this matter are only administering a law which is bad in itself, but do they do all that lies in their power to ameliorate its hard conditions? We think not, and until alteration in the law for which we strive is brought about, we ask them to give a little thought to those poor old men and women among whom by the changes of life they may one day find themselves.

THE THREATENING EPIDEMIC OF INFLUENZA.

THE statistics of the health of London issued by the Registrar-General down to the present time do not prove that there is any increasing prevalence of influenza. Altogether last week 7 deaths from this cause occurred in the metropolis—2 in North, 3 in East, and 2 in South London. At the same time, it must be confessed that in ordinary medical practice all over, and not least in the West, cases are cropping up which are undoubtedly influenza, and that in some instances the disease has attacked many of the members of a household in succession. The cases which have hitherto come to our knowledge have been of a comparatively mild type, the catarrhal symptoms being prominent, the nervous less marked, though instances of severe neuralgic pains during the attack and of much depression afterwards have not been wanting.

BOVINE TUBERCULOSIS.

THE importance of the relation of bovine to human tuberculosis is gradually becoming recognised; but the disease in the cow has itself great economic significance, apart from the fact that it may be a source of danger to the human being. Measures dealing with the disease are being discussed in many different countries, and relate to two different aspects of the subject, namely, what means are to be adopted for preventing the transmission of the disease to the human being by means of meat and milk, and what are those which can be recommended for exterminating the disease in cattle. The latter includes the former, since if the disease is exterminated, infection from meat and milk ceases. But is it practicable? The French Minister of Agriculture proposes to bring forward a measure which provides for the compulsory slaughter of every obviously tuberculous animal; for the compulsory testing by tuber-

culin of suspected animals, and the subsequent slaughter if the reaction is positive; partial compensation being allowed for animals killed. In a large agricultural country such a compulsory measure, as the *Journal of Comparative Pathology and Therapeutics* points out, would be very expensive, the cost for the first year amounting to £200,000. There are some who advocate the Danish system, the essence of which is a voluntary testing and slaughtering or isolation of tuberculous animals, the Government defraying the expense of the tuberculin and the testing. The sixth International Veterinary Congress, held at Berne, voted against the Danish system and against the other suggestions which were made. Perhaps the time is not yet ripe, from a broad political point of view, for the extermination of bovine tuberculosis by radical measures. But there is no doubt that expense ought to be no great obstacle, since the result obtained would greatly improve the breed of cattle as well as their utility to man in the quality of the milk and meat which they afford. A more practical view of the matter to take, before this extermination is decided upon, is to learn the danger to mankind from the consumption of tuberculous meat and milk, and this might certainly be accomplished to a great extent by the Government.

CONTAMINATED OYSTERS.

A NUMBER of ladies and gentlemen—probably about twelve—who attended the Stirling County Ball on October 1st, have since been seized with typhoid fever, the result, it is alleged, of eating contaminated oysters. Three deaths have now occurred as a result of this more or less mysterious affair. Perhaps the assumption that oysters were the cause is hasty and premature. There are possibilities of fallacy, and these must be carefully excluded before a correct judgment can be reached. The matter is being thoroughly investigated by the various authorities concerned.

MR. CHAPLIN AND THE ISLINGTON GUARDIANS.

WE are glad to learn that Mr. Chaplin, the President of the Local Government Board, has promptly directed his attention to the subject of the treatment of children detained in the Islington Workhouse under remand from the police-court, and has taken steps to remedy the serious neglects therein found by Sir John Gorst and Mrs. Barnett when they recently visited the Cornwallis Road Workhouse of that parish. It will be remembered that according to Mrs. Barnett's published statement they found six boys in a room 15 feet square, without tables or chairs, eating their dinners on the floor; for washing purposes a pail was brought in. In this ward the boys lived, ate, and slept, sometimes for three weeks and sometimes longer. In the week previous to the visit there were fifteen lads sleeping there, three in a bed. The girls were no better off. On these facts being brought to the attention of Mr. Chaplin, he at once sent an inspector to visit the workhouse, and arranged that the existing state of things should be immediately remedied, and it was promised that this should be done, and it was, we believe, carried out on October 26th, the complaint having been made on the 23rd. The Local Government Board in communicating with the Board of Guardians on the subject, informed them that although they recognised the difficulty in which the guardians may have been placed owing to want of adequate workhouse accommodation in the parish, which has been so long under consideration, they felt that a very grave responsibility rests with the guardians, and especially with the Visiting Committee of the workhouse, for having permitted such arrangements to be made with regard to the children referred to whilst detained in the workhouse as have been shown to have existed. The guardians have stated in a letter to Sir John Gorst that this class of children has always given them much trouble and has been difficult to deal with. The guardians have pointed out

that the Industrial Act of 1866, under which these children are sent to the workhouse, was passed before the School Board came into existence. Now, however, many of these children are in custody through the action of the School Board officers, and the workhouse is not the proper place for them. The guardians are of opinion that they ought to be remanded to the truant schools of the School Board, where there would be proper provision for their care and control at a small expense. Mr. Chaplin may be congratulated, and certainly deserves credit, for the promptitude and efficiency of his action in this respect, and Mrs. Barnett will have the satisfaction of knowing that her visit, and the prompt action of Sir John Gorst and herself, have had an immediate and most beneficial effect.

THE GENERAL MEDICAL COUNCIL.

We understand that—as a circular letter addressed to the members of the General Medical Council elicited the fact that in the opinion of a minority, large enough to possess the statutory power to demand a meeting of the Council, it was desirable to hold a meeting at the usual date in November—it has been determined to summon a meeting on November 20th. It is intended that the Committees shall meet at the Council Office in Oxford Street, but the full meetings of the Council itself will be held at the Royal College of Physicians. This will be, we believe, the thirteenth occasion on which the College has extended this hospitality to the Council. Judging from the amount of business which, so far as is at present known, is likely to come before this meeting, the session will not, in all probability, be prolonged. Certain penal cases adjourned from last May will come up for consideration, and a few new cases may be submitted by the Penal Cases Committee, but the most important item of business is an application from the Apothecaries' Hall of Ireland for the appointment of assistant examiners in surgery, and a communication from the Privy Council as to the continuance of the Conjoint Board between the Royal College of Surgeons and the Apothecaries' Hall of Ireland for the purpose of examining candidates who have already passed part of the examinations and may be preparing for the remainder. Reports from the Visitors and Inspectors of examination will probably be ready for presentation, as also the report of the Inspector of Public Health examinations.

DR. HERZ.

The following is an authentic report of the recent and present condition of Dr. Herz. Dr. Frazer and Dr. Lauder Branton saw Dr. Herz together on October 22nd. On examining the heart the apex was not felt, and the cardiac dulness was normal; but there was a loud, double, bellows murmur over the aorta, the systolic part of it being propagated up towards the clavicles; and the diastolic part, which was loud and prolonged, was propagated down the sternum almost to the nipple. At the apex there was a loud, twangy systolic murmur, and there was a great deal of tenderness over the area round the apex. The anginal pain, which has been so severe, had somewhat shifted its position, being less severe towards the apex and more severe and more continuous at the base of the heart. The pulse was from 80 to 84, and was irregular, the pulse rate varying in successive minutes. The arteries were seen to be locomotive, the locomotion being very well marked in the radial artery between the finger and thumb, and in the dorsal arteries of the feet. The spleen was enlarged, the splenic dulness being three inches and a-half in the axillary line, and the spleen itself very tender. The liver was also tender, but normal in size. The patient feels faint on sitting up, and, in addition to the anginal pain, suffers greatly from pain in the head, which was located on the left side in the upper parietal region. He has also a feeling of great constriction round the neck. The extremities are very cold, requiring the constant application of hot-water bottles, and the left leg is markedly

colder than the right. Vomiting has been very troublesome. A report to the effect that it was impossible for Dr. Herz to travel without great danger to his life was sent to France, supported by the medical authorities who had seen Dr. Herz before—namely, Sir Russell Reynolds, Sir Richard Quain, Sir William Broadbent, Sir George Johnson, Professor Ferrier, and Professor McHardy. Since the 22nd Dr. Herz has not been so well, and his heart symptoms have been very distressing.

COST OF THE RECENT ANNUAL MEETING.

The Honorary Treasurer's balance-sheet has been printed, and a copy forwarded to each of the 922 subscribers to the Arrangement and Reception Fund. The net receipts figure at £4,306 2s. 3d., and are comprised under three heads, namely: Subscriptions, £3 269 4s.; surplus from museum account, £1,122 15s. 8d.; and interest on deposit, £1 2s. 7d. Excluding the 300 guineas contributed by the Metropolitan Counties Branch, the other 921 subscriptions average the large sum of £3 4s. each. The net expenditure is £2,613 4s. 11d., and the balance remaining in the treasurer's hands, after payment of all expenses, is as much as £1,782 17s. 4d. The Executive Committee has consequently resolved to return at once to every subscriber one-half of his or her subscription. This procedure, involving an outlay of about £1,074 12s., will still leave an estimated surplus of about £108, the disposal of which will rest with the General Committee.

DIPHTHERIA IN LONDON.

The mortality from diphtheria in London showed a marked increase during last week. The deaths referred to this disease in the metropolis, which had been 56, 76, and 61 in the three preceding weeks, rose again to 72 during the week ending Saturday last, November 2nd. This is, with one exception, the highest number recorded in any week for nearly two years, and about double the corrected average for the corresponding weeks of the ten preceding years. Only 4 of the 72 deaths from diphtheria last week were of persons above the age of 20 years; 35 were of infants and young children under 5 years of age, and the remaining 33 deaths were nearly all of children between 5 and 10 years of age. After distributing the deaths that occurred in the Metropolitan Asylums Hospitals and other institutions to the sanitary areas to which the patients belonged, it appears that diphtheria was proportionately most fatally prevalent in West London, 5 deaths being recorded in Kensington, 4 in Hammersmith, and 4 in Chelsea sanitary areas. Three cases belonged to Hampstead, 7 to Islington, 4 to Mile End Old Town, 5 to Battersea, and 9 to Greenwich sanitary areas. There were 671 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, November 2nd, against 659, 687, and 675 at the end of the three preceding weeks; 102 new cases were admitted during the week, against 115 in each of the two preceding weeks.

SIR THORNLEY STOKER.

On November 2nd Sir Thornley Stoker, President of the Royal College of Surgeons in Ireland, was entertained at dinner in the College by a large number of his professional friends. The special object of the demonstration was to offer their congratulations on his having recently received the honour of knighthood. About 150 persons sat down to dinner. The chair was occupied by Sir Charles Cameron, and there were also present the Right Honourable the Lord Mayor, the Right Honourable C. R. Redington, the Right Honourable J. M. Meade, Sir John Banks, K.C.B., Sir Edward Sullivan, Bart., Sir Christopher Nixon, Mr. W. Thomson (Vice-President of the College), Dr. Woodhouse, Mr. Swanzy, Professor Bennett, Mr. C. B. Ball, Mr. Melden, Mr. Jacob, Mr. Lentsaigne, Professor Cunningham, Mr. Chance, Dr. Titchborne, Mr. Heuston, Mr. Kendal Franks,

Mr. Story, and Mr. Nixon. The toast of "The Guest" was proposed by the Chairman in very eulogistic terms, and was received with great enthusiasm. Sir Thornley Stoker replied in an exceedingly graceful speech, which concluded in these words: "I accept the sign of your friendship and esteem. I leave here chastened and full of hope and resolve. You have given me a clean leaf on which to write my life in its future relations with those among whom I live and work. I pray that the page may be unsoiled by error or misdeed, and may be worthy of the trust you repose in me." Professor Cunningham proposed "The city we live in," and this toast was responded to by the Lord Mayor.

THE DEFICIENCY OF ACCOMMODATION IN THE METROPOLITAN ASYLUMS BOARD HOSPITALS.

REFERENCE was made in the BRITISH MEDICAL JOURNAL of November 2nd to the recommendation of the Sanitary Committee of the Marylebone Vestry that a conference should be convened with the object of considering the question of hospital provision for cases of infectious disease in London. At a recent meeting of the Vestry of St. George the Martyr, Southwark, the failure of hospital accommodation was the subject of report by the medical officer of health. Dr. Waldo stated that "The greatest number of cases refused admission on a single day during the two weeks under report was seven, five of whom suffered from scarlet fever and two from diphtheria. Of this number—living with parents, brothers, and sisters—three dwelt in one room, two in two rooms, and two in three rooms." Dr. Waldo suggested the need for a more careful selection of cases removed to hospital by the Asylums Board, and the further need for the "speedy erection on the sites already acquired of increased accommodation to meet the requirements of the sanitary authorities."

ECCE ITERUM—MISS COBBE!

It will be remembered that the result of Miss Frances Power Cobbe's last battle with the physiologists was that she fled from the field *relicta non bene parvula* (in the shape of Dr. Berdoe). Since then Miss Cobbe's attitude towards the physiologists has been that of Sir Andrew Aguecheek towards the antagonist whom he had rashly defied: "Plague on't! An I'd have thought he was valiant and so cunning in fence I'd have seen him damned ere I'd have challenged him!" But her spirit is as truculent as ever, and looking about for some feeble folk on whom to avenge her defeat with safety she has lighted on certain Jesuit professors. These theological doctors seem to have been imprudent enough to hint that after all man is of more account than many sparrows, and Miss Cobbe straightway cursed them with a vigour which St. Ernulphus (whose comprehensive malediction may be found set forth at length in *Tristram Shandy*) might have envied. In the *Contemporary Review* for November she is gently but firmly dealt with by Father Tyrrell, S.J. The Church of Rome is not generally credited with any excess of zeal for the cause of science, and we can hardly hail Father Tyrrell as a whole-hearted ally, inasmuch as while allowing the right of vivisection in the abstract he ranks himself with the antivivisectionists in the concrete. He has evidently no patience, however, with the perverted sentimentalism which makes the health of a guinea-pig a more sacred thing than the life of a child. For this expression of a purely academic opinion Miss Cobbe subjects him to a process which may be termed moral vivisection. Father Tyrrell complains that in the discussion of a question which is purely philosophical she has industriously gone out of her way on every available opportunity to vilify his religion, and to say everything that could be most offensive to him as a Catholic, a priest, and a Jesuit. Miss Cobbe wields her pen with all the cruelty that she falsely attributes to vivisectionists; she writes with the purpose of inflicting pain, and too plainly

takes a pleasure in doing so. Fortunately the torture is not applied scientifically, and the toxins of her rancour hurt herself more than her intended victims. We thank Father Tyrrell for teaching us the word "zoolatry," which exactly expresses the state of mind of the antivivisection fanatic who makes the feelings of animals the object of a tender regard which he is far from showing for those of men.

"MASSACRE OF THE INNOCENTS."

UNDER the above title the *Sun* has been doing excellent service by publishing a series of statements and communications tending to show the facility with which illegal abortion can be procured, the methods by which it is done, and the manner in which so-called "stillborn" children can be disposed of. No doubt there is a considerable amount of truth in the statements made respecting these matters, and the evidence lately given before the Certification of Death Committee of the House of Commons revealed the defects in the law which our contemporary so prominently brings to public notice. In pursuing inquiries on these subjects, much care and caution have to be exercised, otherwise too much zeal in the course adopted may lead to erroneous conclusions and the publication of unreliable reports. We notice that Dr. Ady, of Brixton Hill, on behalf of himself and his daughter, Mrs. Graham, has written a trenchant letter to the editor of the *Sun* of November 5th, in which, after alluding to the visit they received from certain persons, who reported thereon, he says that "the narrative as given was a distinct perversion of the truth from beginning to end," and he further requests "that, in common justice to himself, prominent publicity should be given to his communication." This, we are glad to record, has been done. As we understand, the police authorities have been made fully acquainted with details, and that inquiries are still pending, we refrain at present from further comments.

A CONVALESCENT HOME FOR MIDDLE-CLASS CHILDREN.

At the invitation of the trustees of the Yarrow Home a large party visited Broadstairs on October 26th to inspect that institution. The Home has been founded and endowed for the benefit of children recovering from illness, who may be expected to derive permanent advantage from a temporary stay at the seaside. They are admitted irrespective of nationality or creed, but a certain degree of social selection is enforced, it being stipulated that their home-training shall have been such as to make them fit companions for other respectable and well-mannered children. In considering the best direction in which to devote a large sum of money in the most useful manner for the benefit of children, it was felt that the wants of the very poor were already to some extent provided for by existing agencies, but that there were many people of very limited means, but at the same time highly respectable, too sensitive and self-respecting to seek help from ordinary charities or to let their wants be known outside their own circle, who in time of adversity suffer much privation, and whose children lack many of the aids to recovery after illness which are open to those who are either above or below them in the social scale. It was deemed that the granting of assistance to such people, by providing a seaside home for their children when in weak health or when recovering from illness, would be one of the best directions in which a benefaction could be applied. Hence the erection of this convalescent home for the reception of fifty boys and fifty girls of the class mentioned. As examples of the class for which it is provided the prospectus mentions "the children of the minister of limited means, the widow who had seen better days, the unsuccessful professional man, the struggling artist, the clerk with a small income, the skilled foreman—all of whom are under the obligation of maintaining a respectable appearance on very limited means." Every precaution will be taken to exclude children carrying infec-

tion, and the institution is not to be used as a holiday resort, nor for children suffering from incurable complaints, nor are patients requiring active medical treatment to be admitted. The land on which the building stands is situated on the south side of Broadstairs, and has an area of over ten acres, and although it does not actually touch the sea front, control has been secured over all intervening land, so that it shall not be shut in. The building is a handsome structure, with plenty of air and light, and provided with ample space in its corridors, verandahs, and play rooms for amusement and variety, even in bad weather. Provision is made for warming the air in the corridors, lavatories, and bath rooms, by hot-water radiators, so as to make it a comfortable residence in the winter months. It is evident that the planning of the building has been a matter of very anxious consideration, and that Mr. Yarrow and his able architect, Mr. Barrow Emanuel, have spared no pains in the endeavour to make the institution perfect in every detail; and although there are various points in regard to which it would not be difficult for those accustomed to hospital construction to suggest alterations, perhaps improvements, the results of the architect's efforts have been the production of a building which is on the whole admirably suited to its purpose, and one could not but feel how much better off a convalescent child would be in such a home, at the nominal cost of 5s. a week, than in the ordinary seaside lodgings to which it would otherwise be committed, even if it got to the seaside at all. At the termination of the inspection of the buildings, Mr. Yarrow explained that one of his objects in asking medical men to visit the institution was that they might see for themselves what sort of a place it was, and the sort of patient to whose use he wished it to be devoted, for he felt sure that none knew so well as doctors of those hard cases for whose benefit it was intended. Sir William Broadbent afterwards spoke as to the necessity of such an institution, and expressed the high appreciation of those who had seen it of the well-directed generosity which had led to its erection and endowment.

REGIUS PROFESSORSHIP OF SURGERY IN DUBLIN.

The Academic Council of the University of Dublin met on Wednesday, November 6th, to elect a Regius Professor of Surgery, in succession to the late Sir George Porter, Bart. There were three candidates, and the voting ultimately resulting in a tie between Dr. Ball and Sir W. Stokes, the Provost's casting vote was given to Dr. Ball, whom he declared nominated to the Board for election. It appeared, however, that it would be necessary to consider a technical point which was raised, and the meeting was accordingly further adjourned to Friday, November 8th.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

We are glad to find that the arrangements which have been made by the honorary librarian to obtain and preserve in the Library of the British Medical Association a complete set of the theses presented and sustained at the Medical Faculty of Paris are becoming more and more valued as the existence of the collection becomes better known. The intrinsic importance of the theses varies very greatly, but it is rare to find one which does not possess at least some temporary value. Very frequently, on the other hand, these essays are of great practical importance. Owing to the system commonly followed in Paris a thesis frequently embodies the practice and matured opinion of some one or more of the leading teachers of the Paris hospitals, the custom being for the professor to assign to some promising pupil, who has reached the stage in his academical career when it is necessary to produce a thesis, the duty of working up some particular point in pathology or in therapeutics. These points are sometimes, no doubt, very minute, but the work is as a rule very thoroughly done, and the inquirer, who finds an exten-

sive, if not complete, bibliography of the subject, will not ask too curiously whether it is due to the industry of the aspirant or of somebody else, some convenient "ghost." The fact remains that a collection of these theses is a mine of information on topics of current medical and surgical interest. We believe that nowhere in London, and probably nowhere in the United Kingdom, can a complete set of these theses for recent years be consulted except in the Library of the British Medical Association. The set for the academic year 1894-95 is now complete: it comprises 557 theses as compared with 547 in the previous year. The index of authors and subjects prepared at the end of each year has now been issued for 1894-95, and has been placed in the Library.

PROFESSIONAL DEFENCE.

On November 2nd, Dr. C. J. Allan, Lasswade, was the recipient of a very gratifying testimonial from a large body of the profession in Scotland, and of the public in his district, in connection with his successful and public-spirited resistance to a lawsuit under circumstances which have been more than once referred to in the *BRITISH MEDICAL JOURNAL*. The proceedings were held in the Town Hall of Bonnyrigg and the meeting was presided over by the Provost of the place. After referring to Dr. Allan's integrity and devotedness to work, and the nature of the attempt made to damage his good name, the Chairman, on behalf of a large body of subscribers, asked Dr. Allan's acceptance of a surgical dressing case, along with a cheque for some 200 guineas. Thereafter a deputation from the Edinburgh Branch of the British Medical Association was introduced, consisting of Dr. R. W. Philip, Honorary Secretary, and Dr. P. A. Young. The latter gentleman, who had been an old class-fellow of Dr. Allan's, presented him in the name of his colleagues in the Edinburgh and other Branches of the British Medical Association, with a cheque for close on £100. This was followed by a further gratifying testimonial from Dr. Allan's professional brethren in the immediate neighbourhood of Lasswade, which had been subscribed to with remarkable unanimity and cordiality. Dr. Allan, in a frank and modest reply, said that he had not in the present instance fought solely for his own hand. He felt that if he had drawn back he would have played a coward's part in respect of the interests of the profession at large. Thereafter Mrs. C. J. Allan was presented with a tea and coffee service by Mr. A. P. Purves, W.S., on behalf of a number of friends, as a token of their appreciation of her untiring co-operation with her husband in every movement affecting the interests of the people of the district.

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

The Berlin correspondent of the *Times* states that the official statistics of the cases of diphtheria treated by the antitoxic serum which have just been published, give some interesting details as to the success of the new method. The investigation of this subject was set on foot by the Ministry of Medical Affairs, which addressed its inquiries to physicians, both in public and private practice. Answers to the number of 1,349 were returned dealing with 6,626 cases, of which 2,460 were treated in hospitals. Out of the total of 6,626 patients, 86.5 per cent. recovered, and 12.9 per cent. died, while the remainder were still under treatment. Of the hospital patients 80.5 per cent. recovered, and 19.5 per cent. died. The mortality was highest (34 per cent.) in the Government district of Liegnitz, and lowest (7 per cent.) in that of Munich. In 4,871 cases the physicians expressed their views as to the value of the antitoxic serum. In 55.6 per cent. of these cases the remedial effects of the serum are characterised as certain, and 30.8 per cent. as probable, while in 13.6 per cent. the method apparently produced no effect. The serum was described as "decidedly harmful" in only 60 cases, of which 42 recovered and 18 died, and as "innocuous" in 4,644 cases. In these 60 cases the patients

suffered from cutaneous eruptions, albuminuria, pains in the joints, disturbance of the heart's action, nephritis in three cases, and general debility. It is not, however, believed that the inquiry has proved that such symptoms are of more frequent occurrence in consequence of the antitoxic treatment, though cutaneous eruptions and pains in the joints may, it is thought, be looked upon as likely to accompany the method. The authorities have come to the conclusion that the treatment with the serum exercises a favourable influence on the course of the disease, and that a continued employment of it is justified.

A FRESH ENCROACHMENT.

The number of attempts which are now being made in various directions to curtail the liberty and diminish the modest emoluments of the medical profession is extraordinary. The latest is not one of the least audacious. The Portpatrick Parish Council advertised recently for a Parochial Medical Officer and Public Vaccinator, at the munificent salary of £40 a year. Among the conditions attaching to the appointment was the following: "He shall attend private patients at the scale of fees fixed by the Parish Council, copy of which can be obtained from the Clerk." The attention of the Local Government Board for Scotland was called to this proviso as to private fees for cases, and we have before us a letter in which the Secretary to the Board states that "the parish council are not entitled to dictate to their medical officer what fees he is to charge his private patients." The parish council have now rescinded the resolution as to the scale of fees for private patients, but the fact that such a proposal has been made officially is a sign of the times, which is rendered the more serious by the fact, which we quote on the authority of the *Eastern Morning News*, that no fewer than twenty-two legally qualified medical men were candidates for the appointment, apparently under the conditions as originally advertised. Our contemporary adds: "It would appear that the competition amongst medical men is so severe that even these hard conditions do not prevent a rush of applicants for an ill-paid post. Yet one reads that there are 2,000 medical students attending the lectures at Edinburgh University this session. Where are they all to find employment?"

NEGLIGENT SALE OF POISONS.

THE steps taken during the last two or three years by the Pharmaceutical Society, and also by the police authorities, to enforce observance of the law relating to the sale of poisons cannot fail to be productive of benefit to the public by lessening the danger of accidental poisoning and even helping to prevent the misuse of poisons for suicidal or other unlawful purposes. The propriety of restricting the sale of poisons, and even of potent medicinal preparations to the hands of persons possessing special knowledge of their dangerous nature is so obvious that the argument against this restriction on the ground that it confers a monopoly of the supply of poisonous articles is not worth consideration. It is not for the benefit of chemists and druggists that the sale of poisons has been placed exclusively in their hands, but solely for the public good. At the same time it is essential that the persons who are authorised by law to sell poisons should be scrupulously observant of the precautions which the Legislature has held to be requisite in dealing with poisons. Labelling and the registration of sales in the poison book ought always to be strictly carried out by them. That this is not always done appears from the evidence given at two recent inquiries held by Dr. Danford Thomas and Mr. Braxton Hicks. In one case cyanide of potassium was sold, and in the other a vermin killer containing strychnine, but neither of the sellers kept a poison book, or registered the sales in the manner directed in the Pharmacy Act. This is negligence of a kind that the Pharmaceutical Society would do well to take cognisance of, not only because of the

danger attending it, but also because it might be made use of as an argument against the restriction of the sale of poisons to chemists and druggists. Fortunately neglect of this kind constitutes an offence which can be dealt with by the police authorities independently of the Pharmaceutical Society, and it is highly desirable that the provisions of Section 17 of the Pharmacy Act should be made use of when occasion arises.

ABSTINENCE AND SAFE RAILWAY TRAVELLING.

OVER a million of men are employed on the railways in the United States, and of late years there has been a growing feeling on the part of railway directors and managers to promote the sobriety of the men by official measures. The most thoroughgoing action is that of the Chicago and Alton Company, one of whose rules is that any conductor, trainman, engineer, fireman, switchman, or other employee who is known to use intoxicating liquors will be promptly and permanently discharged. Several other companies have a similar rule. Nearly all the leading American railroads forbid the sale of intoxicants at restaurants on the line, and forbid their employees to enter a drinking saloon. These rules have been rewarded by the increased safety of the passengers as well as of the employees, the health, activity, and efficiency of the latter having improved by the increase of abstaining practices.

COUNTY SANITARY SURVEYS.

A REPORT recently issued from the pen of Dr. W. Williams, the county medical officer of health for Glamorganshire, on a sanitary survey of the county carried out by himself, is worthy of especial notice, and calls for great commendation as a piece of county work of a high order of merit. With the beneficial effects of the cholera sanitary survey conducted during recent years by our State Department of Public Health at Whitehall most of our readers are fully aware, and the effect has been of a far-reaching nature, since the surveys have been of a practical character that appealed to all sanitary bodies who had the good of their areas of jurisdiction at heart, and seemed well fitted to meet the needs of a variety of districts, especially in so far as the scope of their recommendatory portions was concerned. But even so, this State survey did not cover the whole of England and Wales, or anything like it. We are wondering whether, for example, it more than touched the fringe of Glamorganshire, and in these circumstances Dr. Williams has done wisely in his decision to go through his county, district by district, in much the same way as did the officers at Whitehall in their round of inspections. The method of his reports says much for the plan of campaign adopted, and certainly he has amassed an array of well-marshalled facts which will be of the greatest possible help to him and his Council in future dealings with the constituent authorities of the county. He treats of each district from the point of view of past sanitary history, so far as records show it, and then, coming to quite recent times, he sets forth sanitary conditions more or less immediately prior to his own survey, and concludes with an account of the district as he found it at the time of his special visit. We venture to think also that the report is a document which will be helpful outside as well as inside the county, and trust it is but the precursor of many another. Indeed we would wish to see each county health officer setting about the accomplishment of a like task, and carrying it out in the same liberal-minded manner and the same painstaking efficiency. If each county had but its proper equipment in the shape of a medical officer of health, and he had compassed such a piece of work as is now in question, our country would be in possession of such information as would enable the authorities, both local and central, to lay hands at once upon any spot where inherent dangerous defect prevailed, and thus ease the way for any drastic remedy which seemed to be called for.

PARLIAMENTARY BILLS COMMITTEE.

A MEETING of the Parliamentary Bills Committee was held at 429, Strand, on October 23rd.

Present :

Mr. ERNEST HART, in the Chair.

Dr. J. WARD COUSINS, President of Council.

Dr. S. H. AGAR (Henley-in-Arden).	Dr. W. J. MICKLE (London).
Dr. D. B. BALDING (Royston).	Dr. C. H. MILBURN (Hall).
Dr. E. W. BATTEN (Gloucester).	Dr. J. W. MILLER (Dundee).
Mr. GEORGE BROWN (London).	Mr. C. H. WATTS PARKINSON (Wimborne Minster).
Dr. J. S. CAMERON (Leeds).	Dr. H. H. PHILLIPS-CONN (Reading).
Dr. W. A. CARLINE (Lincoln).	Dr. G. E. SHUTTLEWORTH (Richmond Hill).
Dr. W. F. CLEVELAND (London).	Dr. R. SOMERVILLE (Gala-shiels).
Mr. GEORGE EASTES (London).	Mr. C. T. STREET (Newton-le-Willow).
Mr. E. H. GALTON (London).	Mr. J. TAYLOR (Chester).
Dr. BRUCE GOFF (Bothwell).	Mr. T. J. VERRALL (Brighton).
Mr. J. D. HARRIES (Shrewsbury).	Dr. W. L. WINTERBOTHAM (Bridgwater).
Mr. J. H. HEMMING (Kimbolton).	Dr. S. WOODCOCK (Manchester).
Dr. C. HOLMAN (London).	
Mr. EVAN JONES (Aberdare).	

Letters and telegrams of apology for non-attendance were received from Dr. Bridgwater, Dr. A. J. Harrison, Mr. Victor Horsley, Mr. Jones Morris, Dr. Murphy, Dr. James Ritchie, Mr. D. Spanton, and Dr. Urquhart.

The resolution of the annual meeting appointing the Committee was read.

On the motion of Dr. CLEVELAND, seconded by Mr. GALTON, Mr. Ernest Hart was reappointed Chairman of the Committee.

The minutes of the last meeting were confirmed.

The CHAIRMAN said the first things they had before them were resolutions of the annual meeting referred to the Committee that day from the Council. The first item was the following resolution :

That in the opinion of this meeting it is expedient that an Act of Parliament should, as soon as possible, be passed providing for the registration and education of medical, surgical, and obstetric nurses ; and the Council of this Association are therefore requested to consider this matter, and to take such measures as may seem to them advisable to obtain such legislation.

The Council having referred the matter to them, he thought that before the Committee could with advantage take any practical steps in the matter it would be very necessary to ascertain the opinion of the various nursing bodies. He thought the best way to enable the Committee to form an opinion was that the representatives of the nursing bodies should be invited to attend a conference, when the whole matter could be discussed.

After a good deal of discussion it was proposed by Mr. C. H. WATTS PARKINSON, seconded by Dr. WINTERBOTHAM, and carried unanimously :

That the Chairman be instructed to call a conference of the representatives of the various nursing bodies, to obtain the opinions and ascertain their views on this subject.

The next item for the Committee was the following resolution of the general meeting.

We also instruct the Council to take immediate steps to have Section 20 of the Metropolitan Poor Law Act, 1889, repealed, which prevents workhouse infirmaries from being used for the clinical instruction of medical students in practical midwifery, while pupil midwives are now admitted ; and also to petition the committees, medical staffs, and, if need be, the subscribers to the City of London Lying-in, the British Lying-in, and the Clapham Maternity, to withdraw their rule which excludes male medical students from clinical instruction at these hospitals, seeing that these are now used by pupil midwives.

The best plan would probably be to adjourn their action in this matter until they got further information on the points. They did not know the precise wording of the rules of the various institutions. If the matter was adjourned, they could get information and copies of the rules of the various institutions, which could be sent out to the Committee for

their information, and the matter could be discussed at the next meeting.

The recommendation of the Chairman was approved.

The CHAIRMAN said that the following resolution, which was passed in the Public Medicine Section of the recent annual meeting, had also been referred to the Committee :

That in the opinion of this Section, and in view of the fact that the Royal Commission on the effect of tuberculous food on human health by the terms of their appointment were restricted to tuberculosis, it is desirable that a Royal Commission be appointed to consider the whole question of meat supply and inspection, and that a copy of this resolution be sent to all the Ministers of State.

He said that the matter was a very serious one affecting the public health, and he proposed that representations on the subject should be made to the Presidents of the Local Government Board and of the Board of Agriculture.

It was proposed by Mr. HEMMING, seconded by Dr. SPOTTISWOODE CAMERON, and resolved :

That the Chairman be requested to make representations to the effect of the resolution passed in the Public Medicine Section of the recent annual meeting to the Presidents of the Local Government Board and the Board of Agriculture.

The CHAIRMAN said the next item for the Committee was the following resolution, also passed in the Public Medicine Section of the annual meeting :

That this Section desires to reiterate the opinion which has been expressed at previous meetings of the Association, that the interests of the public, no less than the just demands of medical officers of health, require that the same security of tenure which is enjoyed by medical officers of health of the metropolis and Scotch counties and Poor-law medical officers should be conceded to medical officers of health, and requests the Parliamentary Bills Committee to take such steps as may be expedient to bring this matter under the notice of the Local Government Board, with the hope that the Committee will see their way to print and circulate Dr. Whitelegge's address as an excellent summary of the merits of the question, together with an abstract of the discussion.

The Committee would remember that a deputation from the Committee went to the President of the Local Government Board on the subject. It was received by Sir Walter Foster, who received the suggestions very favourably in a general sense, but he pointed out that the power was not in the hands of the Local Government Board, but the sanitary authorities. Probably the best course to adopt would be to renew that deputation, since there was a new Government in power.

After some discussion it was proposed by Dr. WARD COUSINS, seconded by Mr. GEORGE BROWN, and resolved :

That the President of the Local Government Board be requested to receive another deputation on the subject of the tenure of office of medical officers of health.

The CHAIRMAN said he had received a letter from Mr. Victor Horsley, stating that as the Subcommittee to which the Amendments of the Medical Acts and the Midwives Bill had been referred had not met since the last meeting of the Committee owing to the vacation, he had nothing further to report.

Dr. WOODCOCK said the Subcommittee had drafted another Bill for the registration of midwives, which had been referred to the Branches for their opinion and the Subcommittee were still awaiting those opinions.

Dr. WARD COUSINS (President of Council) said seeing that the Registration of Midwives Bill, which was before Parliament, had been withdrawn, would it not be well to wait until they had some other Bill on the subject before Parliament for the Committee to act ?

Dr. WOODCOCK said, to a large extent, the Committee succeeded in getting the last Bill withdrawn on the promise that the attention of the profession would be drawn to the subject, and likely to give the Legislature some guidance in the matter. The Lancashire and Cheshire Branch had appointed a Committee to consider the matter, and they had commenced the revision of the Bill, making certain alterations, additions, and amendments, and they hoped to present something which would be acceptable to the profession and the public.

On the motion of Dr. WOODCOCK it was resolved :

That the following subcommittee be appointed to take over the same reference as the previous subcommittee, and be requested to consider

any resolutions of the general meeting or of Branches referring to the Midwives Bill, and to report thereon: The Chairman, Dr. Bateman, Dr. Batten, Mr. George Brown, Dr. Spottiswoode Cameron, Dr. Galton, Mr. Victor Horsley, Mr. Evan Jones, Dr. Milburn, Dr. Shuttleworth, Dr. Somerville, and Dr. Woodcock.

NURSING IN PROVINCIAL WORKHOUSE INFIRMARIES.

The CHAIRMAN said that, as a new Government had come into power, he thought that it would be very desirable that they should call the attention of the President of the Local Government Board to the question of nursing in workhouse infirmaries which had been dealt with in the reports of the JOURNAL. The Committee would remember that they had a letter from Mr. Shaw Lefevre promising that the whole matter should be carefully considered, and a great deal of good had been done by the Local Government Board and its inspectors taking up the question; and if an abstract of facts was now sent to the new President it would be very useful.

It was proposed by Dr. SHUTTLEWORTH, seconded by Dr. MILBURN, and resolved:

That an abstract statement relating to the administration and nursing of provincial workhouses be sent by the Chairman to the President of the Local Government Board, and to ask his attention to the same.

CASES OF GRIEVANCE.

The CHAIRMAN said they had next to consider certain cases of grievance which had been brought to the notice of the Committee. The first was that of Surgeon-Captain J. F. S. Fowler, who was forced to resign his commission under painful circumstances. He happened to be present at the committing of an act of indecency by some young militia officers; he interfered to stop it, and, as a matter of fact, did stop it, but he did not report the matter, as he did not consider it his duty to do so, medical officers having no disciplinary power over combatant officers. Moreover, the senior captain of the regiment was present. Dr. Fowler had, however, been forced to resign his commission for not reporting the occurrence. He (the Chairman) had all the papers of the case, and was inclined to think that Surgeon-Captain Fowler had been very hardly used. The Committee would remember that on a previous occasion when there were grievances of army medical officers before them, they referred the matter to a Subcommittee of Surgeon-General Cornish, Mr. C. N. Macnamara, and himself, to consider all the facts and take what steps they thought necessary; and perhaps they would refer this matter to the Subcommittee, adding to it the name of Deputy Surgeon-General Don.

On the motion of Dr. SOMERVILLE, seconded by Mr. GEORGE EASTES, it was resolved:

That the case of grievance of Surgeon-Captain Fowler be referred to a Subcommittee consisting of the Chairman, Surgeon-General Cornish, Mr. C. N. Macnamara, and Deputy Surgeon-General Don, with power to take what steps are deemed necessary, and, if necessary, to get some member of Parliament to bring the matter up in the House of Commons.

The next case was that of Surgeon Francis J. Lea, late a medical officer of the Royal Navy, who was dismissed the service after trial by court-martial on April 30th of the current year on a charge of "insubordination and contempt." The facts of the case were set forth in the BRITISH MEDICAL JOURNAL of June 15th, 1895. Mr. Lea had further sent a summary of the case to the individual members of the Committee. He was anxious that the Parliamentary Bills Committee should send a letter to Mr. Goschen, and particularly wished that the medical aspects of the case should be brought to the notice of the naval authorities, which Mr. Lea believed had never been done. He looked upon the captain as being in a state of health that made it dangerous for him to be in active command of the ship, and accordingly placed him on the sick list. For this he was tried by court-martial, and dismissed the service. Several members of Parliament considered that Mr. Lea had been very badly treated. Mr. Lea was particularly anxious that the case should be submitted to an expert in mental diseases. This was a case which the Committee might also refer to the Subcommittee, adding to it a lunacy specialist, Dr. Mickle.

The proposal of the Chairman was approved.

The next case was that of Surgeon-Major Gardner, whose case was referred to a Subcommittee of the Parliamentary

Bills Committee. Surgeon-Major Gardner asks that their recommendations should now be submitted with the view of pressure being brought upon the Secretary of State for War to reinstate him.

The last case was that of Dr. Lionel Smith, which had already been several times alluded to in the BRITISH MEDICAL JOURNAL. Dr. Smith now suggested that the Committee should again write to the Secretary of State for the Colonies. Dr. Smith thought that Mr. Chamberlain's reply was curt and disrespectful to the Committee. He (the Chairman) did not know what further steps they could take.

DEATHS UNDER ANÆSTHETICS.

TRACHEOTOMY IN APPARENT DEATH FROM CHLOROFORM.

Dr. F. C. MACNALLY, M.A., M.D. (Winchester) writes: In cases of death from chloroform, the means used to restore animation seem so unavailing that I venture to suggest immediate tracheotomy as a remedy. The instant rush of air into the lungs would act as a great stimulant to the nerve centres which would have the best effect. Those who have performed tracheotomy must be aware of the instantaneous relief it gives, and from my own experience I believe it would set going the functions which are in abeyance.

CHLOROFORM.

Mr. W. H. MALING (Sunderland) writes: I was very glad to see Mr. E. C. Cripps's letter in the BRITISH MEDICAL JOURNAL of October 19th, drawing attention to the fatalities during the administration of chloroform, and had hoped that the seriousness of the matter would have induced others to take it up. On looking through the JOURNAL for this year I find that, including the case given in your last number, 23 deaths under anæsthetics have been recorded, and possibly there are others that are not reported. In all these cases except one, in which the A. C. E. mixture was used, chloroform was the lethal agent. In the place of this record—over two deaths a month—it certainly appears "almost criminal" to persist in administering such a dangerous drug. It seems to me that to a certain number of the profession the idea of giving an anæsthetic is synonymous with the administration of chloroform. Why is this? Why is not ether given more often? There are very few cases in which it is inadmissible, and in the minds of those who have had experience of both anæsthetics there exists no shadow of doubt that it is infinitely safer than chloroform. I feel sure that were every case requiring an anæsthetic to be carefully considered, and unless any grave contraindication to its employment existed, ether were selected in preference to chloroform, the mortality during anæsthesia would be very largely reduced.

Mr. H. LATHAM, Senior House-Surgeon, forwards us the following report of a death under chloroform which took place at the Stockport Infirmary on October 23rd: The patient, a young woman aged 18, was admitted on the previous evening suffering from an extensive empyema of the right side. It was thought advisable to place her under an anæsthetic the next morning for the purpose of relieving her by either resecting a portion of a rib, or by free incision in an interspace and drainage. Consequently on the next day chloroform was administered on a piece of lint. Her breathing before the administration was somewhat embarrassed, but the heart was fairly good. A few minutes after starting the administration the breathing suddenly ceased, the lips became livid, and the pulse was imperceptible at the wrist. Not more than a drachm and a-half had been administered, and not more than four minutes had elapsed from the commencement. The operation had not commenced when the breathing stopped, as the patient had only arrived at the tonic stage. Artificial respiration was kept up for over half an hour without avail; hot cloths were applied to the precordial region, and the battery was freely made use of. As a last resource a knife was plunged into the pleural cavity, and close on two pints of purulent matter came away. The patient gave no signs of recovery from the first.

We have been favoured by Dr. E. M. HAINWORTH with the following report of a case of a chloroform fatality, which recently occurred at the Hull Royal Infirmary on October 15th. H. J., a bricklayer, aged 60, a short, very stout and

thick-necked man, was admitted with a ruptured eyeball, which necessitated excision. He had some bronchitis and an aortic murmur. The heart sounds, however, were loud, and the pulse regular and strong. On account of the bronchitis chloroform was given, and anaesthesia easily induced. He had just lost his reflexes, and the operation was about to be commenced, when he turned blue in the face and stopped breathing. Artificial respiration was performed, and inversion, amyl nitrite, the battery, and ether and strychnine injections were tried without any subsequent effort at respiration, although the heart continued to beat for about ten minutes. *Post-mortem* examination showed there was atheroma of the aorta, old disease of aortic and mitral valves, a large quantity of fat about the heart, and slight fatty degeneration of the cardiac muscle. In the lungs were signs of bronchitis. Between 2 and 3 drachms of chloroform (Duncan and Flockhart's) were given.

THE ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

THE new Royal Edinburgh Hospital for Sick Children, which has been built in the Sciennes Road, on the site previously occupied by the Merchant Maiden's Hospital, was formally opened by Princess Beatrice last week. Because of the recent bereavement of Prince Henry, the ceremonial part was curtailed as much as possible. The proceedings took place in the Bathgate Ward, in presence of a distinguished company.

The Rev. Dr. Cameron Lees, Dean of the Thistle and of the Chapel Royal, having offered the dedicatory prayer. Mr. Hall Blyth, chairman of the directors, gave a brief sketch of the rise and progress of the institution. The hospital, he said, was originally started by a few gentlemen in Edinburgh in the year 1859, in which year the mortality among children under 5 years of age in the eight principal towns of Scotland was more than 46 per cent. A small house in Lauriston Lane was first acquired, and six months after its opening the directors reported to the first meeting of contributors that there were 10 cases in the wards, and that a very large number of less serious cases had been treated at the outdoor dispensary. Now, 700 indoor patients and over 8,000 outdoor were treated annually. In 1863 the Queen graciously extended her patronage to the hospital, and it became the Royal Edinburgh Hospital for Sick Children. Some years ago the directors found that the limited and imperfect accommodation in the old and oft-extended building in Lauriston Lane compelled them to look afield for a new hospital. They were finally determined to this by an epidemic which broke out among the nursing staff, investigation of which led them to the conclusion that the building was unfit for use as a hospital. The old hospital having been thus condemned, temporary accommodation was got at Flewlands, where work has been carried on for the last three years. In addition to the nursing of sick children, the hospital has for the last few years become a great school for the teaching of diseases peculiar to children, and, recognising this, the directors have made every provision for teaching being carried on under the most approved methods, and theatres for lectures and demonstrations have been provided on the two main floors. The directors owed much to the medical staff and the matron, who had given the whole details of the building their earnest consideration, and had, from time to time, made many valuable suggestions. Thus far the general public had not responded as they ought to have done to the appeal for subscriptions to the building fund, but one munificent benefactor had given £11,500—£6,500 for building one of the wings of the hospital and £5,000 as a fund for endowing ten cots in that wing which Her Royal Highness would be asked to name the "Lady Caroline Charteris Memorial Wing." Not only so, but Lady Jane Dundas had just intimated to the directors her intention of giving a further sum of £7,000, so that all the twenty-four cots in the upper ward of the west wing might be endowed by her in memory of her sister. The total cost of the new hospital, including the acquisition of the site, furnishings and fittings, the dispensary department, the nurses' annexe, the mortuary, laundry and machinery, electric instal-

lation and heating machinery will be about £47,000. Thus the hospital would be started with a debt of £10,000. The old hospital was capable of accommodating 73 patients; the new would accommodate 120.

Her Royal Highness then formally declared the hospital opened, after which the Lord Provost proposed a vote of thanks to the Princess. The Princess was conducted over the hospital, and handed to each of the nurses present a silver badge commemorative of the occasion, the gift of the four physicians of the hospital—Drs. James Carmichael, John Playfair, Joseph Bell, and T. Burn Murdoch.

A ward on the first floor of the building in the east wing was formally named the Beatrice Ward. The Lady Superintendent, Miss Piggott, was then presented with a gold badge, and Mr. Hall Blyth, on behalf of the directors, asked Her Royal Highness to accept a gold enamelled badge as a souvenir of the occasion. These last were replicas of those given to the nurses.

The site of the hospital is on a level piece of ground of about an acre and three quarters in extent. It has a south frontage of 384 feet, and a west of 264 feet. The plan of the main hospital building is in the form of the letter "E." The administrative block is in the centre, and the wards in the two arms cut off by disconnecting cross-ventilating doors. The wards run north and south; the open side of the "E" is towards the south; the administrative block runs east and west. The central block is five storeys in height, the two upper being in the roof. The ward wings are three storeys in height, the upper being partly in the roof. The principal wards are on the ground and first floor, those upon the third floor being spare observation and isolation wards. The kitchen, with larders, milk house, and stores, is on the fourth flat. The dormitories and bedrooms for the domestic staff on the fifth or attic floor. The main entrance is from the south in the centre of the building, and there is a large entrance hall, across the end of which a corridor 10 feet wide extends right and left nearly the whole length of the building. To the right and left of the entrance hall are the suites of rooms for the matron and the resident physicians, and opposite the entrance hall in the centre of the administrative block to the north is the surgical theatre, which has a gallery to hold eighty-four students. To the right of this is the principal staircase, and to the left the service staircase. To the north-east and north-west corners are rooms for the visiting physicians and surgeons, one for each ward. Each of the four principal wards is 84½ feet long, 23 feet wide, and 15 feet high. They are arranged for twenty-four cots, thus allowing 1,215 cubic feet of air space to each child, and 81 superficial feet of floor space. The floor is laid with teak, the walls are finished with polished Parian cement, and the angles are all rounded. There is a small kitchen for each ward, and at the south end of the turret, disconnected by a cross-ventilated lobby, is a bath room, lavatory, a sleep room, and a watercloset. The medical lecture theatre is on the first floor; and in the central block on this floor are the Board-room, museum, ophthalmic room, dispensary, assistant matron's room, staff dining room, and nurses' sitting room. On the second floor the wards are divided into observation, isolation, and spare wards, each with kitchen and lavatory accommodation. In the front are a suite of bed rooms and sitting room for the staff nurses, while in the north side are the bed rooms of the ordinary nursing staff. On the fourth floor are kitchen, scullery, larder, milk house, general stores, servants' hall, sewing and linen room, mattress room, etc. There is a hydraulic lift in the well of the service stair. The building is lighted by electricity, generally by duplicate set of boilers, engines, and dynamos arranged so that either engine may be driven from either boiler in case of accidents. There is a large set of accumulators for night stores. There are open fireplaces in the wards and a hot water heating system.

The building is of red sandstone, and is without unnecessary ornament. The design is based on the English renaissance of the sixteenth century. There are several adjuncts to the main building, namely, the nurses' annexe with bed-rooms for the night nursing staff, laundry buildings, out-patients' department, mortuary and pathological room, boiler houses and engine room. These are connected by covered corridors with the main building. The out-patient depart-

ment, the laundry, and electric light building on the west side are detached from the main building. The architect was Mr. G. Washington Browne, A.R.S.A.

Their Royal Highnesses were entertained at dinner in the evening at the Balmoral Hotel by the Lord Provost of Edinburgh, the Very Rev. Dr. Cameron Lees, Dr. James Carmichael, Dr. Joseph Bell, and Mr. Hall Blyth, C.E.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWER, *General Secretary.*

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held at the Hospital, Hastings, on Thursday, November 28th, at 3.30 P.M. Dr. Allen will preside. Notices of papers and other communications to the meeting should be sent forthwith to the Honorary District Secretary, J. W. BATTERHAM, Bank House, Grand Parade, St. Leonard's.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of this District will be held at the Kent and Canterbury Hospital on November 28th, at 3 P.M. Mr. Robert Hook, of Ramsgate, in the chair. Tea and coffee will be served in the Board Room of the hospital after the meeting. All members of the South Eastern Branch are entitled to attend these meetings and to introduce professional friends. Agenda:—Dr. Copestake: Pleuritic Effusion; Aspiration; Rare Sequela. Dr. Robinson: Poisoning by Boracic Acid in Milk. Dr. Tyson: Appendicitis. THOMAS F. RAVEN, Honorary District Secretary, Barfield House, Broadstairs.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The next meeting of this Branch will be held, by the kindness of Dr. Pringle, at the County Asylum, Bridgend, on Tuesday afternoon, November 19th.—D. ARTHUR DAVIES, M.B., Swansea.

BATH AND BRISTOL BRANCH.

A SPECIAL meeting was held on October 30th in the Medical Library of University College, Bristol; CARRY COOMBS, M.D., President, in the chair. There were also present fifty members and two visitors.

Alteration of Rules.—Dr. MICHELL CLARKE moved, and Dr. J. STEWART seconded, "That papers shall not exceed twenty minutes in delivery, and that each subsequent speaker shall be limited to ten minutes." Dr. SKERRITT moved in Rule 8, after "year," to insert "always excepting that no member shall so retire who has not served upon the Council for the full term of four years." These additions to the rules were carried by the requisite majority of two-thirds.

Communications.—Dr. WATSON WILLIAMS read a paper on the Thyroid Gland and Graves's Disease. After recapitulating the chief points in the symptomatology, he discussed the arguments for and against the origin of the disease in a perverted action of the thyroid gland and the question of anæmal interference. In the discussion which followed, the President, Messrs. W. H. HARRANT, C. A. MORTON, F. R. CROSS, Mrs. MICHELL CLARKE, SHINGLETON SMITH, E. LONG FOX, CHAR. STRAUB, T. FISHER, and J. STEWART, took part, and Dr. WATSON WILLIAMS replied. — Dr. J. G. SWAYNE read a paper

on Cases of Induced Premature Labour in certain Diseases of the Mother not obstructing Delivery. Drs. AUST LAWRENCE and W. O. SWAYNE discussed the paper.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.

A MEETING of the North London District was held on October 31st at the London Temperance Hospital, Hampstead; Sir W. O. PRIESTLEY in the chair.

Paper.—Dr. CLEVELAND read a paper on the Prophylactic Clothing of the Body, chiefly in relation to Cold. The President spoke approvingly of the paper, and alluded to the prevalence of injurious scantiness in the clothing of women and children. He quoted M. Pasteur's experiment, showing that a fowl could be rendered susceptible to inoculation with woolsorter's disease by cold, although not susceptible under its usual circumstances. Dr. NORMAN KERR gave some personal experiences of the effects of Arctic temperatures. Dr. BAILEY spoke of the evident infectiveness of common catarrh. Dr. CLEVELAND replied.

Cases.—Dr. COLLINS and other members of the staff showed several very interesting cases in the wards of the hospital.

Votes of Thanks.—Votes of thanks were unanimously passed to Dr. Cleveland, to the hospital staff, and to the hospital authorities.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THE autumn meeting of this District was held at Reigate on October 10th, Mr. J. B. HALLOWES, of Redhill, in the chair.

Confirmation of Minutes.—The minutes of the Croydon meeting were read and confirmed.

Next Meeting.—It was resolved that the next meeting of the Branch should be held at Upper Norwood on the second Thursday in March, 1896, and that Dr. J. H. GALTON be invited to take the chair.

Discussion on Diphtheria.—This discussion was opened by Dr. SIDNEY MARTIN, Mr. H. G. PLIMMER following him, and showing cultures and slides. The medical aspect of the disease was then reviewed by Dr. WASHBOURN, and Dr. C. HOLMAN, Dr. J. H. GALTON, Dr. ADENEY, Dr. OGLE, Dr. O. OWEN-FOWLER, Mr. J. S. TURNER, and Mr. MAUDE joined in the discussion which followed Dr. Washbourn's paper. Mr. C. J. SYMONDS then dwelt with the disease in its surgical aspect, and this paper was spoken to by Dr. WALTERS. Dr. PHILPOT (medical officer of health for Croydon) wound up the discussion with a paper on the Disease in its Relations to Public Health. Over fifty members and visitors attended the meeting, and showed great appreciation of the thorough manner in which the various papers treated of the disease in its different aspects.

Dinner.—After the meeting thirty members and visitors dined together.

SYDNEY AND NEW SOUTH WALES BRANCH.

THE usual monthly meeting of the Branch was held at the Royal Society's Room on August 30th, Dr. E. J. JENKINS, President, in the chair. Thirty seven members were present. The minutes of the previous meeting were read and confirmed.

Personal Changes.—The President announced that Dr. E. T. Thring had been elected Honorary Secretary; and that since the last meeting Dr. Huxtable had died, and that the Council had forwarded a resolution of sympathy to Mrs. Huxtable. Dr. CRAIG commented upon the loss sustained by the Branch through the death of Dr. Huxtable.

New Member.—The following new member was announced: Dr. Goldsmid, of Cobarr.

Communications.—Dr. WILKINSON exhibited a patient suffering from Persistent Dropping of Fluid from the Nose. Drs. GEORGE and SYDNEY JONES made some remarks upon the case.

Dr. CLUNN read a paper on seven cases of Laparotomy for Intussusception in very young children. A discussion ensued in which Drs. JENKINS, O'HARA, SCOT SKIRVING, GORE, GILLON, CRAIG, WILLIAM CRISHOLM, SPRINGER, THRING, and SYDNEY JONES took part. Dr. CLUNN replied.

PROCEEDINGS OF THE COUNCIL.

At a meeting of the Council, held at the office of the Association, 429, Strand, London, W.C., on Wednesday, October 23rd, 1895:

Present:

Dr. J. WARD COUSINS, President of Council, in the chair.
Sir J. RUSSELL REYNOLDS, Bart., F.R.S., President.
Mr. HENRY T. BUTLIN, Treasurer.

Dr. JAMES BARR, Liverpool.
Dr. G. B. BARRON, Southport.
Dr. RAYNER W. BATTEN, Gloucester.
Dr. MICHAEL BEVERLEY, Norwich.
Mr. LANGLEY BROWNE, West Bromwich.
Dr. J. SPOTTISWOODE CAMERON, Leeds.
Dr. JOHN CAMPBELL, Belfast.
Mr. ANDREW CLARK, London.
Dr. H. RADCLIFFE CROCKER, London.
Dr. E. H. DICKINSON, Liverpool.
Dr. J. LANGDON H. DOWN, London.
Brig.-Surgeon-Lt.-Col. E. F. DRAKE-BROCKMAN, London.
Dr. DAVID DRUMMOND, Newcastle-on-Tyne.
Mr. GEORGE EASTES, M.B., London.
Dr. W. A. ELLISTON, Ipswich.
Dr. D. W. FINLAY, Aberdeen.
Sir B. WALTER FOSTER, M.D., M.P., Birmingham.
Dr. J. H. GALTON, Upper Norwood.
Dr. BRUCE GOFF, Bothwell.
Dr. WILLIAM GORDON, Exeter.
Dr. OGILVIE GRANT, Inverness.
Dr. H. HANDFORD, Nottingham.
Mr. JOHN D. HARRIES, Shrewsbury.
Mr. J. HUGHES HEMMING, Kimbolton.
Dr. O. HOLMAN, London.

Mr. T. VINCENT JACKSON, Wolverhampton.
Mr. T. R. JESSOP, Leeds.
Mr. EVAN JONES, Aberdare.
Mr. JORDAN LLOYD, Birmingham.
Mr. O. N. MACNAMARA, London.
Mr. H. J. MANNING, Salisbury.
Dr. J. W. MILLER, Dundee.
Mr. R. H. B. NICHOLSON, Hull.
Mr. O. H. WATTS PARKINSON, Wimborne Minster.
Dr. CHARLES PARSONS, Dover.
Dr. F. M. POPE, Leicester.
Mr. HENRY POWER, London.
Dr. ROBERT SAUNDY, Birmingham.
Dr. ALFRED SHEEN, Cardiff.
Dr. E. MARKHAM SKERBITT, Clifton.
Mr. NOBLE SMITH, London.
Dr. R. SOMERVILLE, Galashiels.
Mr. HENRY STEAR, Saffron Walden.
Mr. JAMES TAYLOR, Chester.
Dr. J. ROBERTS THOMSON, Bournemouth.
Dr. THEOPHILUS W. TREND, Southampton.
Mr. T. JENNER VERRALL, Brighton.
Dr. W. F. WADE, Birmingham.
Mr. F. WALLACE, London.
Mr. JOSEPH WHITE, London.
Dr. W. L. WINTERBOTHAM, Bridgwater.
Dr. S. WOODCOCK, Manchester.

The minutes of the last meeting having been printed and circulated, and after amendment by the insertion of Sir Walter Foster's name as being present at the Council meeting of July 31st last, were signed as correct.

Read letters of apology for non-attendance from Dr. Bridgwater, Mr. Wheelhouse, Dr. Philipson, Mr. Jones Morris, Dr. Oswald, Dr. Urquhart, and Dr. Russell.

The following resolution, which was passed as a rider to the interim report of the General Practitioners Committee at the annual meeting held in London on July 30th last, was then considered:

That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical, or surgical, or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing.

Resolved: That a copy of the resolution be forwarded to the General Medical Council.

The second rider, of which the following is a copy, which was also carried at the same meeting, was then considered, namely:

That in the opinion of this meeting it is expedient that an Act of Parliament should, as soon as possible, be passed providing for the registration and education of medical, surgical, and obstetric nurses and the Council of this Association are therefore requested to consider this matter, and to take such measures as may seem to them advisable to obtain such legislation.

Resolved: That the rider be forwarded to the Parliamentary

Bills Committee, and that they be requested to report to the April meeting of the Council.

The following resolution, which was also carried as a third rider to the report of the General Practitioners Committee, at the annual meeting held in London was then considered:

That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties, and to devote a portion of the income and funds of the Association for these purposes.

Resolved: That a Special Committee be appointed to take the resolution of the annual meeting into consideration, and report to the next meeting.

Resolved: That the following be the Committee:

The President of Council, the Treasurer, Dr. Bridgwater, Dr. Ogilvie Grant, Dr. Gordon, Mr. Hemming, Mr. Macnamara, Mr. Jones Morris, Dr. Parsons, Dr. Roberts Thomson, Mr. Verrall and Mr. Wallace.

Read resolution of annual meeting of members of July 31st:

That we view with deep concern and regret the recommendation of the General Medical Council to the medical examining bodies that they should admit students to their final examination who present a certificate stating that they have "conducted personally" only three, and "been present at" only nine confinements: and as the General Medical Council has refused in November, 1890, to alter this recommendation, we instruct our Council to petition the General Medical Council to recommend that no student be admitted to his final medical examination until he presents a certificate showing that he has personally conducted at least thirty confinements under the direct supervision of a registered medical practitioner.

We also instruct the Council to take immediate steps to have Section 20 of the Metropolitan Poor Act, 1869, repealed, which prevents workhouse infirmaries from being used for the clinical instruction of medical students in practical midwifery, while pupil midwives are now admitted; and also to petition the committees, medical staffs, and, if need be, the subscribers to the City of London Lying-in, the British Lying-in, and the Clapham Maternity to withdraw their rules which exclude male medical students from clinical instruction at these hospitals, seeing that these are now used by pupil midwives.

Resolved: That to the words "medical practitioner" be sent to the General Medical Council, and the latter part of the resolution be sent to the Parliamentary Bills Committee.

Resolution of the annual meeting, copy of which is as follows was then considered:

That as Sections 7 and 8 of the Medical Act, 1883, provide for the election of only five direct representatives to the General Medical Council by the registered medical practitioners resident in the United Kingdom, and as Section 10, Subsection 1, Paragraph c of this Act provides that the General Medical Council may represent to the Privy Council that it is expedient to confer upon the registered medical practitioners resident in any part of the United Kingdom the power of returning an additional number of direct representatives to the General Medical Council; and as the General Medical Council has, in November, 1890, in November, 1891, and in November, 1892, refused absolutely to make such representation; and as the number of registered medical practitioners has increased from 22,713 in 1876 to 32,634 in 1894; and as we medical practitioners were not given our proper number of direct representatives in 1886; and as the registered practitioners contribute all the income of the General Medical Council, by which the Medical Acts are administered, while the twenty universities and colleges represented on the General Medical Council do not contribute any income to it; and as the representatives of the universities and colleges are elected to the General Medical Council by their small Convocations, Senates, and Councils, and not by open vote of all their medical graduates only; and as other important councils, having similar but larger duties to the General Medical Council (such as the Councils of the Incorporated Law Societies of England and of Ireland, the Councils of the Pharmaceutical Societies of Great Britain and of Ireland, and the Council of Veterinary Surgeons) consist of direct representatives only, this Association instructs its Council to take immediate steps to have a Bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one additional direct representative to the General Medical Council.

Resolved: That the General Medical Council be informed that the annual meeting has passed this resolution, and that the Council of the Association has under consideration the means for giving effect to the recommendation.

Read protest of the South Indian and Madras Branch, of which the following is a copy :

The members of the South Indian Branch of the British Medical Association have read with much surprise the resolutions which were passed in the Section of Public Medicine at the annual meeting of the Association lately held in London, and founded on the address delivered by the Editor of the *BRITISH MEDICAL JOURNAL*. They wish to point out that the whole of that address, so far as it refers to the civil portion of the Indian Medical Service, is full of inaccuracies and unjust statements, calculated to reflect discredit in a most unwarrantable manner upon a large body of the profession in India. They feel certain that, had the members present at that meeting been in possession of the true facts regarding sanitary progress in India, and the work done during the past thirty years in India, in both the civil and the military departments, they would not have been induced to accept all Mr. Hart's statements, and to pass such an ungenerous resolution which reflects adversely on them and on the Government they have the honour to serve. They trust that the Council will see fit to give the same publicity to this protest as they have given to the Editor's erroneous and defamatory statements.

Resolved: That the protest of the South Indian Branch be published in the *JOURNAL*.

Read minutes of the General Practitioners Committee of October 22nd.

Resolved: That the minutes of the General Practitioners Committee of October 22nd be received and approved and the recommendations contained therein carried into effect, and that the resolutions passed at the Ethical Section at the late annual meeting be referred to this Committee—namely :

That this meeting is unanimously of opinion that a suitable authority should have powers of control over irregular practice, of the same kind as those exercised by the Incorporated Law Society and the Inns of Court respectively, and urges the Council to approach the Government with this view, with a preference for this Association as the controlling body.

That the Ethical Section of the British Medical Association has revealed the urgent need of some practical steps being taken to deal effectively with the present deplorable lack of *esprit de corps* and want of co-operation in the profession generally, and of which so much undue advantage is taken by the public. As it is to be hoped that much of the existing undesirable state of affairs arises more from ignorance than deliberate intention on the part of those concerned, we respectfully urge on the Council to take such steps as may direct the attention of professors and teachers in the various colleges and medical schools to the advisability of pressing on their pupils on every suitable occasion the importance of the subject, not only as regards their own, but their future patients' interests. We also strongly suggest that special provision should be made in every medical teaching centre for inculcating this most important part of the duties of the medical practitioner or otherwise to do as they in their wisdom may think fit.

That, in the opinion of this Section, members of the British Medical Association should not hold office in any hospital which is not really, as well as ostensibly, a public institution; and members of the medical staff at a hospital having pay wards should not gratuitously attend the inmates of such wards.

That it be a recommendation to the consideration of the Council, in the first place, to include an Ethical Section in the annual programme. In the second place to recommend to each Branch the expediency of constituting its executive council an Ethical Committee, to consider questions arising within its area, and settle them if possible; or failing this to refer them to the General Council of the Association. Thirdly, and it is further suggested to the Council the expediency of their forming an Ethical Committee to receive and report upon such matters as may be referred from the Branches or in other way arising.

That in the opinion of this meeting the employment of unqualified assistants in visiting patients is injurious to the interests of the public as well as those of the profession.

That in the opinion of this Section any practitioner who wilfully violates generally received rules of professional ethics should not be met in any professional intercourse whatever save in cases of urgent danger to an individual patient.

That advertising in every shape is highly derogatory to the profession, and that the Council be requested to use every effort to suppress it.

That the Council be requested to take steps to prevent members of the British Medical Association accepting posts in medical aid or other kindred societies; and that, in the opinion of the Section, no practitioner who accepts office in any society of this kind ought to be eligible for membership of the Association.

That it be suggested to the Council to open a fund, to be subscribed to by members of the Association, to assist to indemnify bodies of medical men practising in the United Kingdom in their contests against the combined action of the friendly and other benefit societies.

That the Council be requested to communicate with the universities and medical corporations, with a view of discouraging their graduates and diplomates from taking office under medical aid associations or under-

taking any engagement or appointment calculated to degrade the profession.

Read resolutions passed at the annual meeting in the Public Health Section, of which the following are copies :

That the Public Health Section of the sixty-third meeting of the British Medical Association begs to recommend that representations be made to the Secretary of State for India as to the utter inadequacy of the sanitary administration of the Government of India to give the most elementary protection to the public health of the inhabitants of Her Majesty's Indian empire, and that a copy of Mr. Ernest Hart's address be forwarded to the official authorities at home and in India requesting their attention to the points urged therein.

That in the opinion of this Section, and in view of the fact that the Royal Commission on the effect of tuberculous food on human health by the terms of their appointment were restricted to tuberculosis, it is desirable that a Royal Commission be appointed to consider the whole question of meat supply and inspection, and that a copy of this resolution be sent to all the Ministers of State.

That this Section desires to reiterate the opinion which has been expressed at previous meetings of the Association, that the interests of the public, no less than the just demands of medical officers of health, require that the same security of tenure which is enjoyed by medical officers of health of the metropolis and Scotch counties and Poor-law medical officers should be conceded to medical officers of health, and requests the Parliamentary Bills Committee to take such steps as may be expedient to bring this matter under the notice of the Local Government Board, with the hope that the Committee will see their way to print and circulate Dr. Whitelegge's address as an excellent summary of the merits of the question, together with an abstract of the discussion.

Resolved: That the first resolution be laid on the table.

Resolved: That the last two resolutions be referred to the Parliamentary Bills Committee.

Read resolution and communication of the Psychological Section.

THE PRIORY, ROEHAMPTON, S.W.,

5th August, 1895.

DEAR SIR,—I enclose copy of a resolution which was passed at the Psychology Sectional Meeting on Friday, August 2nd. Will you kindly forward it to the proper quarter, also kindly acknowledge its receipt? With apologies for troubling you.—Yours truly, JAMES CHAMBERS, F. FOWKE, Esq.

Recommendation to the Council of the British Medical Association from the Section of Psychology. The following resolution was adopted at the Sectional Meeting on Friday, August 2nd:

That in view of the desirability for a closer comparison of the experiences of alienists with those of neurologists in reference to the psychical relations of epilepsy, to which attention has been called in Dr. Gowers's address, a recommendation should be forwarded to the Council of the British Medical Association that a committee be appointed to collect information on the subject. It is further recommended that a grant be made to defray the expenses of the inquiry.

The committee to consist of the following:

Dr. Gowers	Dr. C. E. Beavor	Dr. Mickle
Dr. G. M. Robertson	Dr. Conolly Norman	Dr. James Taylor.

Resolved: That the officers of Section be requested to inform the Council the nature of the proposed inquiry and the probable amount of grant required.

Read resolution passed in the Section of Diseases of Children, of which the following is a copy :

11, CHANDOS STREET, CATENDESH SQUARE, W., August 2nd, 1895.
Section of Diseases of Children.

DEAR SIR,—I beg to transmit to you for submission to the Council of the British Medical Association the following resolution, which was adopted unanimously by the Section of Diseases of Children at its meeting this day:

"That this Section thinks it desirable that in the new edition of the *British Pharmacopoeia* the maximum doses of powerful drugs suitable for children at various ages should be indicated.

I am, dear Sir, yours faithfully,

JORN H. MORGAN,

President of the Section of Diseases of Children, 1895.

FRANCIS FOWKE, Esq.,

General Secretary, British Medical Association.

Resolved: That the resolution be referred to the Therapeutic Committee.

Read letter of Mr. Garrett Horder with suggestions for the arrangements of the annual meeting.

Resolved: That Mr. Horder be informed that the arrangements of the annual meeting are in the hands of the Council, and due consideration will be given to his letter.

Read letter from Dr. William Mitchell, calling attention to testimonials from medical men in circulars.

Resolved: That the attention of the Council having been called to the testimonials of medical men issued in circulars,

the attention of the members be called to the resolution of the Council (3279). "Resolved: That in the opinion of this Council the granting of testimonials, which are used for the purpose of advertising proprietary drugs and similar articles, is inconsistent with the dignity of the profession, and opposed to its best interests."

Resolved: That a copy of the resolution be sent to those members whose names appear on the advertisement.

Resolved: That the minutes of the Journal and Finance Committee of to-day's date be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Journal and Finance Committee contain a report upon various JOURNAL matters as to the payment of articles, etc., and editorial matters. The accounts for the quarter amounting to £28,097 4s. 11d. and auditors quarterly report.

In reference to letter from the Statistical Department of the London County Council, informing the Council of the Association that a quinquennial census will be taken for London next year, and stating the opinion of the Local Government and Taxation Committee of the London County Council that such census will not be of much value beyond the single purpose for which it is taken if it is confined to a mere enumeration of population, and not extended to the other subjects dealt with in the census of 1891.

Resolved: That the Council of the British Medical Association think that it is desirable that a census in every sanitary district having a population in 1891 of more than 50,000 should be made in 1896, and should include an enumeration of the inhabited houses, etc., and the names, ages, and sex of their occupants on the night of the census, the Council being of opinion that vital statistics based upon results of a census taken more than five years ago are far from reliable.

Resolved: That in the opinion of the Council of the British Medical Association no enumeration for the purpose of the Equalisation of Rates (London) Act, 1894, will be reliable unless the enumerators also record the names, ages, and sex of the persons present in each house on the night of the census.

Resolved: That copies be sent to the London County Council and the Local Government Board.

Read letter from Surgeon Francis J. Lea, complaining of his dismissal from the Navy.

Resolved: That the letter of Surgeon Francis J. Lea be referred to the Parliamentary Bills Committee.

Resolved: That Messrs. Price, Waterhouse, and Co. be reappointed public auditors for the ensuing year, in accordance with By-law 26.

Resolved: That of the 123 candidates whose names appear on the circular convening the meeting, 122 be and they are hereby elected members of the Association.

Resolved: That the minutes of the Premises and Library Committee of the October 22nd be received and approved and the recommendations contained therein carried into effect.

The President of Council reported that up to the present time there was no invitation received for 1896.

SPECIAL CORRESPONDENCE.

PARIS.

The French Surgical Congress.—The Hygiene of Crèches.—Proposed Bacteriological Laboratory for the City of Paris.

THE French Surgical Congress held its first meeting on October 21st. A considerable number of the leading members of the medical profession were present, but there were some conspicuous absentees. Dr. Eugene Boeckel, of Strasbourg, in his presidential address, paid a tribute to the memory of Alphonse Guérin, Baron Larrey and Verneuil, and finally Pasteur. Among living medical celebrities, Sir Spencer Wells came in for his share of praise. The general meeting of the members took place on Friday, October 25th, at 8 o'clock—or, more correctly speaking, it ought to have taken place; but as at such an early hour there were only a few stray members, the Committee of the Association did not appear until 8.30. Professor Bousquet, of Clermont Ferrand, asked that in future the general meeting should be held at 11.30; he also complained of the absence of cordiality among the Paris hospital surgeons in their relations with the members of the Congress who wish

to visit their wards and be present at their operations during the session of the Congress. The financial condition of the Congress is excellent, and will be still more satisfactory as time goes on. The Congress intends to be its own printer and publisher. The annual banquet took place on October 24th—a bad preparation for the next morning sitting at 8 o'clock. About sixty members were present. M. Eugene Boeckel, the President, made an eloquent speech, and M. Delorme, M. Demons, and M. Jannasch spoke in the name of the military, provincial, and foreign surgeons.

M. Napias, at a meeting of the Société de Médecine Publique d'Hygiène Professionnelle, drew attention to the necessity of strict supervision of the organisation of *crèches*, which are in danger of becoming "infant depositories" generally unhealthy and even dangerous to life. Each child should have all its own toilet requisites set strictly apart for its own use. The question of feeding is another vital matter needing reform. In some of the *crèches* M. Napias told the Society that sterilised milk is used in litre measures; when the feeding hour comes it is poured into the feeding bottles and mixed with water from the pump. He suggests that the staffs of the *crèches* should be better versed in the elements of their business, and that the mothers be given some simple instruction in the principles of hygiene. The children are frequently ill on Mondays after passing Sunday with their parents, and being fed on food unsuitable to their age.

M. Dubois has urged on the Municipal Council that the bacteriological laboratory of the City of Paris should make such researches, analyses, and diagnoses as may be required by the Paris medical men and those of the Seine department in connection with those contagious diseases of which the bacillus is known. He also urges that children who have recovered from diphtheria should not be allowed to return to school without a certificate from this bacteriological laboratory.

The Société d'Agriculture and the Société de Médecine Vétérinaire de Milan have opened a subscription to collect funds for the erection of a statue to Pasteur.

BERLIN.

Professor von Pettenkofer on the Causation of Cholera.

IN the Berlin weekly *Die Nation*, Professor Pettenkofer has published an article on "The Cholera Epidemic of 1892," in which he combats what he calls the "bacteriological-contagionist view" of the causes of cholera. His chief arguments are: (1) That the Hamburg cholera epidemic of 1892 ran almost exactly the same course as the epidemics of 1832 and 1848; that, in fact, the mortality in 1892 was greater than in the two previous great epidemics, the numbers being—in 1832, 11.29 per 1,000; in 1848, 10.50 per 1,000; and 1892, 13.44 per 1,000; and this in spite of the vigorous measures taken from a bacteriological point of view. These measures, he adds, have in Hamburg shown themselves to be absolutely ineffectual. (2) That the contagiousity of cholera receives no support from the history of the Hamburg epidemic of 1892. Pettenkofer quotes from Wolter's publication on the epidemic, that in 12,473 cases, of which 6,746 ended fatally, the attack remained isolated in the household, and that only in 4,483 cases—about a quarter of the total number—with 1,859 deaths, was more than one person in a household attacked.

The relative immunity of Altona Pettenkofer alleges to be owing to other causes than the water supply. And in regard to the fact that six Hamburg institutes, where the water was not the ordinary town supply, remained immune, Pettenkofer quotes Wolter, who states that sixteen other institutes in Hamburg, although supplied with water by the town waterworks, remained immune as well.

In conclusion, Pettenkofer expresses the opinion that the many millions which have been needlessly wasted for contagionist measures would have been better employed in improving the sanitary conditions of the dwellings.

FLORENCE.

Deaths from Preventable Diseases.—Taxation in Italy.—The Water Supply of Florence.

IN an article in *La Salute Pubblica*, Signor Ceratti has expressed the opinion that the satisfactory results of drainage methods in England depend on the efficiency of individual house

drainage as distinguished from public drainage. English residents in Italy would endorse this opinion. Signor Cerutti's suggestion that British sanitary legislation is somewhat oppressive probably gives the key to the whole situation. Legislation alone will not reduce the death-rate to its minimum. In Italy a popular appreciation of the dangers of defective sanitation is wanting. It rests with the medical profession to preach the doctrine of sanitary reform. At present the scholastic bacteriologist inclines to the belief that bad smells are innocuous unless specific cultures can be obtained from the sewage emanations whence they originate, and thus lends the weight of his influence to the maintenance of a most defective state of sewage removal. In the city of Florence there has been a marked decrease in the annual average number of deaths from preventable diseases for the past five years as compared with the preceding lustrum. The only exception is diphtheria, but the official memorandum states that this is apparent only and not real, accounting for it on the ground that formerly deaths from diphtheria were frequently registered as croup. The number of deaths from diphtheria registered by the Florence municipality for the first eight months of this year is 26, as compared with 54, 72, and 42 for the years 1894, 1893 and 1892 respectively. This decrease is largely due to antitoxin treatment but partly also to improved sanitary conditions.

The Italian Council of State has just approved the imposition of a new tax on gas and electric light. This will doubtless have the effect of checking the already somewhat belated generalisation of these methods of illumination in Italy. At the same time there has been a sudden and inconsistent elevation of the assumed amount of income of the professional classes on which the amount of income-tax is based, which will mean a heavy additional burden on the shoulders of the foreign medical man; the heavy tax on tobacco has stimulated an active contraband trade in that article over the Swiss frontier.

Recent events at San Marcello will give an idea of the difficulty attending the procuring of a further water supply for Florence. An eminent engineer, Signor del Poggetto, had developed a scheme in conjunction with the municipal authorities of Florence for the appropriation of a spring, with the laudable object of supplementing the somewhat scanty water supply to that city. The men employed at certain neighbouring pin factories, and some agricultural labourers, got wind of the scheme, and made a demonstration in force to obstruct the preliminary operations. The intruders were forced to retire, but returned on September 24th, supported by a band of sixteen carabinieri. Local interests were again equal to the occasion, and mustered to the number of 500 operatives, who in spite of drawn bayonets, surrounded the intruders, and marched them back to San Marcello. Judicious *pourparlers* and a certain "dignified restraint" on both sides, averted a general engagement, and, apart from a broken arm and a flesh wound, no serious consequences ensued. Local authorities qualified to judge maintain, moreover, that the water in question is not good enough for Florence.

CORRESPONDENCE.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR,—I am sorry once more to be obliged to make an appeal to the profession on behalf of the British Medical Benevolent Fund, but for the last few months we have at every meeting of the Committee overdrawn our account at the bank, and have even then been unable to afford assistance in many cases where it was felt that help ought to be rendered.

In September £44 was all the money available, and six grants were made amounting to £90. At the meeting on Tuesday, October 29th, there were twenty cases to be considered besides those postponed from September, and only £34 were in hand to meet the claims, and till the end of the year there is no prospect of improvement in our financial condition unless through the response of the profession to our appeal.

During the year 174 cases have come before the Committee, and 119 grants have been made amounting to £1,038. This gives an average of about £9, but, as a matter of fact,

our grants to be of the greatest use require to be £12 or £18 so as to enable a monthly instalment of £1 or 30s. to be paid throughout the year, and lately we have been obliged to reduce the allowance to the inadequate sum of £5 or £6 sometimes with the promise that a second application may be sent in at the end of six months if funds permit.

Applications and the severity of the cases which come before us increase year by year, and the subscriptions and donations, on which we depend, do not keep pace with them. We have over 100 annuitants, selected from among the applicants who are over 60 years of age, but the special function of the donation department, for which I now plead, is to relieve those who, owing to death or illness, find themselves in difficulties which timely help may enable them to overcome, and naturally winter is the season in which such cases are most numerous and urgent.

The working expenses of the Fund are extremely small; there is no rent for offices, no expenditure on advertisements, and no payment of officers, except for clerical assistance, which is absolutely necessary, as the mere writing connected with the investigation of cases and the collection of funds and keeping accounts has become more than can reasonably be expected from men who have other work to do.

The cases selected for relief at the last meeting are illustrations of the everyday work of the Fund:

1. A widow, aged 55, whose husband had become incurably insane after two years' illness; she has three young children, and is penniless. Granted £12.
2. A medical man, aged 78, quite unfit to work. Two daughters at home, one an invalid, the other recovering from scarlet fever. Granted £12.
3. A widow with young children, and unable to earn anything on account of influenza. Granted £8.
4. A lady, 66 years of age, and quite deaf. Granted £5 for six months.
5. A lady who has maintained herself as a midwife, but is now too infirm to undertake cases. Granted £5.
6. A governess, aged 83, who has been obliged to give up work on account of illness. Granted £5.

These cases show the urgency of the distress, and I may mention that a member of the Committee who was present at the meeting has already sent me a donation of twenty guineas.—I am, etc.,
W. H. BROADBENT,
Brook Street, Nov. 5th. Treasurer, B.M.B.F.

THE SCHOTT TREATMENT OF HEART DISEASE.

SIR,—I have read with great interest Dr. Saundby's account of the Schott method of treating certain forms of heart disease, and have been greatly struck (as one could not fail to be) with the enormous diminution of the area of cardiac dulness which followed a few minutes in a bath or an equally short time occupied in the so-called Schott movements. These changes in the area of cardiac dulness are so remarkable—so much more remarkable than the changes produced in the pulse rate and the sphygmographic tracing—that I venture to make a few remarks upon them.

Now the volume of a sphere is stated to be $\frac{4}{3}\pi r^3$ where $\pi = 3.14159$ and r is the radius of the sphere. If for simplicity's sake we take π as equal to 3, and if we suppose that the dilated heart is a sphere with a radius of 3 inches, then the volume $= \frac{4}{3} \times 3 \times 27 = 108$ cubic inches. If this sphere diminishes in bulk so that the radius is reduced to 2 inches instead of 3, then $V = \frac{4}{3} \times 3 \times 8 = 32$. In other words, the volume of the sphere is less than $\frac{1}{3}$ of its former self.

The heart, of course, is not a sphere, and the above calculation is merely to show that the contraction of a spheroidal body amounting to an inch in all directions means, relatively, an enormous decrease in volume, and with an organ as big as a dilated heart such a decrease must be absolutely very great. When the heart shrinks in the thorax what takes its place? Either the thoracic wall must recede, or the lung must dilate.

The assumption that because the upper margin of the liver is not depressed the lungs undergo no extra expansion, seems to me rather gratuitous. I can at will assume an abdominal respiration with great depression of the diaphragm and protrusion of the abdominal wall, or I can make my respiratory movements assume a thoracic type with great movement of the upper part of the chest, and with very little or no diaphragmatic and abdominal movement. In the latter case the upper part of the lungs undergo an extensive dilatation, while the lower lobes remain quiescent.

If it be possible for the upper lobes to expand in this way,

then not only would this extra inflation tend to overlap the heart, but by exercising pressure would be capable of altering the position of the apex. Therefore I think that Dr. Schott's contention that the fixity of the line of liver dulness and the movement of the apex show that the diminution of the area of cardiac dulness is not due to pulmonary expansion, stands in need of more careful consideration. When a man sits in a bath the pressure of the water is proportioned to the depth to which his body is sunk, and it is obvious that the abdomen has to bear more pressure than the upper part of the thorax. If, therefore, the respiratory movements and the inflation of the lung takes the path of least resistance, it follows that the upper lobes of the lungs would dilate, while the lower lobes, owing to the diaphragm being "loaded" with the pressure of the water, would be relatively quiescent.—I am, etc.,

Wimpole Street, W., Nov. 5th.

G. V. POONS.

THE ADMISSION OF WOMEN TO THE EXAMINATIONS OF THE CONJOINT BOARD.

SM.—In rejecting the petition from the London School of Medicine for Women, the argument was used that medical women in this country had as yet made no contribution to practical medicine. This is perfectly true; but the reason is not one of sex, but of time and opportunity. What chance have we women had of perfecting ourselves in surgery or even in general medicine? We are entirely shut out from appointments in the general hospitals, and even from most laboratories. Besides, although there may be 200 women on the *Register*; most of them have qualified within the last ten years.

Surely, the learned Fellows of the College would not wish us to publish our immature experiences? As regards original research, very few women can afford it. When a parent has been liberal enough to send his daughter to the medical school, he naturally expects her to earn her own living after having qualified. Besides, mere numbers do not count for much, as it must be admitted that many women still enter the profession from unworthy motives—though not in the sense meant by Dr. Charles West. Many of them are religious enthusiasts, who want to go out as medical missionaries, and they take an interest in their medical work only in so far as it is a means to an end. Others, still, believe that self-sacrifice is a specially feminine virtue. Those who take up medicine from love of the work or to earn a living—the only two worthy motives—are unfortunately few.

Dr. Hare denies that women can "create or advance knowledge," and instances mathematics and music. Has he never heard of Sonja Kovalevsky, whose published work was nearly all original, and who has been universally recognised as one of the first mathematicians of the century? And why? Simply because she was able, at an early age, to escape from her gaolers and devote herself entirely to her work. And as music appears to have a closer relationship to the senses than to the intellect, it is not difficult to understand why musical distinction has hitherto been a masculine prerogative.

Why my professional sisters are so keen to have this diploma I never could understand. What more do they want now, when most of the universities are open to them? Last year 28 new students entered the school, and of these 23 were students of the London University. If the College were opened to women I am afraid that the percentage of university students would decrease. And on this account the decision of the College is not altogether a matter for regret.—I am, etc.,

November 3rd.

A MEDICAL WOMAN.

SM.—The Fellows of the Royal College of Physicians, by their vote of October 24th, declined to admit ladies to the examinations for their diploma, but in so doing they did not place any fresh impediments in the way of their gaining a sound medical education or right to qualify, so that their vote was productive of no real good to their own body or the public whom they may say they sought to protect. Still, by their vote they placed themselves on a very high pedestal, for they virtually refused to co-operate with such well-known bodies as the Universities of London and Paris, and yet I am sure they would never for one moment assert that their

examinations are at all comparable with those carried on by the above-named bodies.

My own opinion is that it would be best to let everyone qualify who could, and each would, without any external interference, soon settle down in the position for which they were individually best suited.—I am, etc.,

Surbiton, Nov. 4th.

F. P. ATKINSON, M.D.

UNQUALIFIED LADY DOCTORS.

SM.—The recent decision of the Royal College of Physicians, and the impending question of the formation of a body to be euphemistically called "registered midwives," appear to me to render it imperative that the whole question of the relationship of women to medicine should be exhaustively reconsidered. The public are in perplexity, waiting for light, while the medical profession, in London at all events, offers either no guidance or, worse still, gives inconsistent advice.

Among the many questions involved in the inquiry is that of the position at present occupied by the "certificated" nurse. That these nurses are in reality acting as unqualified assistants, and are being "covered" by physicians and surgeons of standing, I suppose very few will care to deny. To employ an unqualified assistant to visit, prescribe, and operate upon patients has been justly condemned and wisely punished: but it is at present quite open to any medical man to employ a nurse in that capacity without incurring odium.

I hold no brief either for or against nurses. They are being made use of by the medical profession on the one hand, and by the public on the other, and they are no doubt now becoming alive to the fact. I would, therefore, lay before your readers the following propositions for solution:

1. Ought a nurse to call regularly on a male patient for the purpose of passing a catheter?
2. Ought a nurse to administer an anæsthetic?
3. Ought a nurse to prescribe?
4. Ought a nurse not specially qualified to dispense medicines?
5. Ought a nurse to administer hypodermic medication?
6. Ought a nurse to undertake the sole responsibility of a case of midwifery? (It is not possible to draw a distinction between natural and abnormal labour.)
7. Ought a nurse to receive a case of lunacy into her house, either uncertified or as a single patient?

Now all these are being done by nurses, and it therefore is evident that unless the Royal College of Physicians is prepared to publicly condemn such practices, they have by their recent decision laid themselves open to a charge of inconsistency.

The College has decided that women are not fitted to practise medicine, and refuses to assist in educating them for that purpose. Are not these women still less fitted for the position to which they have quietly attained, by reason of the lack of this very education? The whole situation appears to be rapidly deserving the designations of ridiculous and scandalous.

Women are acting as doctors with the connivance of both the public and the medical profession. The College has, therefore, no right to refuse to openly recognise what it secretly allows. Our true policy is to open the profession widely to women, and sternly and severely to repress unqualified practice, whether on the part of men or women.—I am, etc.,

SIGMA.

November 2nd.

REGISTRARS AND DEATH CERTIFICATES.

SM.—As many medical men are unaware of the regulations issued to registrars with regard to the acceptance of death certificates without inquiry, it may be well to give them here.

Registrars are instructed by the Registrar-General, before registering, to report to the coroner:

1. All deaths occasioned directly or indirectly by violence.
2. All deaths occurring under suspicious circumstances.
3. All deaths the cause of which is stated to be "unknown."
4. All deaths which are stated to have been "sudden," and respecting which no certificate issued by a registered practitioner is produced.

5. All deaths of infants in houses registered under the Infant Life Protection Act, 1872.

No fault can be found with the above, but some registrars seem, as in the case I reported last week, to stretch Regulation 2 most unduly, and also to report cases on other grounds most needlessly to the coroners. A doctor sends me the following instance of a needless inquest:

Dr. Miller, of West Green Road, Tottenham, certified a death as follows: Primary: Mollities ossium; duration 1½ year. Secondary: Fracture of thigh; duration 3 months. The registrar, having regard, I suppose, to Regulation 1, referred the matter to the coroner on account of the fracture. The deputy coroner held an inquest, and Dr. Miller complained of the action of the registrar. The jury expressed the opinion that the case ought never to have come before them. The coroner agreed with this opinion. In this case neither registrar nor coroner was a medical man.—I am, etc.,
Archway Road, N., Nov. 8rd. HUGH WOODS.

THE LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS AND THE TITLE OF PHYSICIAN.

SIR,—Many members of the British Medical Association will be glad to see that a Licentiate of the Royal College of Physicians of London has a distinct right to the title of a physician, according to the learned opinion of the legal authorities named in the BRITISH MEDICAL JOURNAL of November 2nd.

It would be an undoubted advantage to the members of our great Association if an equally high legal opinion were taken on the debatable point of the use of the prefix "Dr." by Licentiates of the Royal College of Physicians. I am myself a Licentiate of the Edinburgh College of Physicians, in addition to my other qualifications, and I have on several occasions had communications addressed to me by the officials of that College with the prefix "Dr." to my name. Now if a Licentiate of these corporations has a right to the title of Physician, then surely, if we drive the matter to its logical conclusion, he has an equal right to the prefix "Dr." for whoever heard a physician addressed as "Mr. So-and-so." I believe I am speaking the sentiment of the majority of our members in saying that we should be delighted if the Council of the British Medical Association would obtain a legal opinion on the point, especially as it would tend somewhat to set at rest the minds of those who take the double qualification, and would in no way hinder University education; for graduates of Universities only have a right to the use of the initials "M.D."—I am, etc.,

Nottingham, Nov. 2nd.

WILLIAM TIBBLES.

SPLENECTOMY.

SIR,—In his article on Splenectomy, Mr. W. D. Spanton gives two tables: one containing leucocythemic cases, the other non-leucocythemic. The former contains twenty-five cases with only one recovery, and in this instance there is reason to believe, with Mr. Knowsley Thornton, that the case was not one of leucocythemia. The conclusion, therefore, to be drawn is that splenectomy is contra-indicated, and in this Mr. Spanton concurs. The second table includes cases of hypertrophy, so called, abscesses, cystic spleen (including hydatids), "lymphosarcoma," etc. In commenting on this table Mr. Spanton says that "among thirty-eight cases of hypertrophy were found twenty deaths after operation." This term "hypertrophy" seems far too vague, and certainly requires some definition. We cannot gather from the cases included in Table II. what the cause of the hypertrophy was. We cannot look upon hypertrophy of the spleen as a simple or uniform condition, and it seems to me that the cause of the enlargement is not sufficiently taken into account in considering the advisability of splenectomy. Thus enlargement of the spleen is found in a series of cases which have been described as "splenic anemia," and in them enlargement of the organ is most probably the result of an underlying and grave disorder, and brought about by an effort on the part of the spleen to eliminate or neutralise morbid products in the blood. In these cases the spleen would seem to be to a certain extent a safeguard, and its removal is as little likely to be followed by success as in

leucocythemia. Moreover, I have known the spleen in such cases decrease in size, and then a patient become worse. I cannot therefore agree with Mr. Spanton when he says that the size of the spleen, by causing pain and discomfort, affords strong reason for removal of the organ, "which may be diverting material which ought to be utilised elsewhere." On the other hand, hypertrophy may be due to syphilis or chronic engorgement from rotation. In these a better result would be expected, as the condition is a more purely local one. This was so in Dr. Malins's successful case, in which the enlargement of the spleen was due primarily to syphilis and subsequent rotation and engorgement, the patient's general condition being fairly good.

Another point to which I would like to draw attention is that in the "anemic" cases, the coagulability of the blood being greatly reduced, the danger of hemorrhage is much greater. Therefore, in considering the question of splenectomy in "hypertrophy" of the spleen, it would be important to bear in mind that the enlargement of the organ may be due to a general and widespread disorder, as leucocythemia, splenic anemia, or else to a local lesion, as chronic engorgement with rotation, abscess, etc. If operation be reserved for these latter the results of splenectomy would probably be more satisfactory than they have hitherto been.—I am, etc.,
Birmingham, Nov. 2nd. DOUGLAS STANLEY, M.D.

SIR,—Since my paper on splenectomy, published in the BRITISH MEDICAL JOURNAL of November 2nd, was read at the London meeting, I have been enabled through the courtesy of Mr. J. Bland Sutton to add 16 other cases to the list then tabulated, and among them an unprecedented record of three successive successful cases by Mr. Bland Sutton, which were published in the *Lancet* of October 19th. The additional cases give the following figures as the total up to that date; and it is very interesting to note that the last 17 recorded by various surgeons have all recovered. The figures now should stand as follows:

Table I.—Leucocythemic ...	25 cases	24 deaths.
Table II.—Non-Leucocythemic ...	75 "	28 "

This gives the death-rate for the last three decades thus:

1865-75 ...	75.00 per cent.
1875-85 ...	36.25 "
1885-95 ...	16.21 "

A progressive decrease as instructive as it is encouraging.—I am, etc.

Hanley, Nov. 4th.

W. D. SPANTON.

REGULATIONS AS TO OUT-PATIENTS.

SIR,—We shall feel much obliged for information respecting the regulations made with regard to the admission of out-patients at any of the London or provincial hospitals or infirmaries.—We are, etc.,

C. A. GRIFFITHS, F.R.C.S.,

T. GARRETT HORDER, M.R.C.S.

Gardiff, Nov. 1st.

WELL-TO-DO PATIENTS IN RATE-SUPPORTED HOSPITALS.

SIR,—Your article upon the "Infectious Hospital Provision for London" in the BRITISH MEDICAL JOURNAL of November 2nd touches upon one very important point, a point which should be remedied as soon as legal powers can be obtained. At a recent meeting of the Metropolitan Asylums Board I obtained from the Chairman the following information—that anybody, rich or poor, can avail themselves of the fever hospitals under our control, and that no legal steps can be taken to enforce payment from those who are in a position to pay for such treatment. This reply was given in answer to a question addressed by me, because I knew that only quite recently certain persons well able to pay for medical attendance had been treated in some of the fever hospitals of the Metropolitan Asylums Board.

It is, in my opinion, manifestly unjust that the poor who cannot procure proper isolation and efficient nursing, and can ill afford to pay for medical help, should be deprived of a single bed by persons who can obtain such assistance at their own homes, but who prefer, on account of their own surroundings, to avail themselves of outside help.

If this is allowed, and I understand the law does allow it,

here can be no limit as to the amount of accommodation which the Metropolitan Asylums Board may be called upon to provide, to say nothing of the injury done to the medical profession by the gratuitous treatment supplied to the well-to-do.

Immediate isolation of the infected poor is absolutely necessary, as the cases occurring in crowded localities tend to spread infection. It is in this way that the large ratepayer benefits, but not as a large ratepayer does it entitle him and his family to free attendance and housing during infection.—I am, etc.,

Maddox Street, W., Nov. 2nd.

SAMUEL OSBORN, F.R.C.S.

THE TREATMENT OF DISLOCATION OF THE PERONEUS LONGUS TENDON.

SIR,—In the BRITISH MEDICAL JOURNAL of November 2nd, Mr. W. J. Walsham records a case of dislocation of the tendon of the peroneus longus, in which he obtained a most excellent result by operation, a new sheath being made for the tendon by turning down a flap of fascia and periosteum from the external malleolus. Mr. Walsham states that he is not aware that similar treatment has "hitherto been done or proposed."

There is, however, an interesting paper in the *Centralblatt für Chirurgie*, 1895, p. 569, by Professor Kraske, of Freiburg, in which are references to various attempts which have been made to remedy luxation of the peroneal tendons by operation. Thus, Albert and Lannelongue, acting upon the supposition that the displacement resulted from shallowness of the groove on the malleolus, obtained permanently good results, the former by deepening the groove with a gouge, the latter by heightening the outer lip of the groove with a periosteal flap. Albert had suggested, as another method, the formation of a new sheath with a flap of periosteum, and Kraske, regarding this as the most rational treatment, adopted it in a case of dislocation of both peroneal tendons of four years' standing. The flap, which was turned down from the malleolus, included a thin scale of bone in addition to the periosteum, as recommended by König. The result was excellent.

I have thought it worth while to draw attention to this independent testimony to the value of Mr. Walsham's method of treatment.—I am, etc.,

Weymouth Street, W., Nov. 5th.

RAYMOND JOHNSON.

THE TREATMENT OF FRACTURES OF THE FEMUR.

SIR,—The views expressed by Sir William Stokes in his paper on the subject of Fractures of the Femur so nearly coincide with those I entertain, and which, now nearly forty-three years ago, I submitted to the notice of the profession, that I feel sure a very little further reflection will adjust the difference.

The important axiom laid down by Sir G. M. Humphry, and endorsed by Mr. Bryant, and accepted by the meeting, should never be lost sight of—namely, that "a fracture of any part of the skeleton, at any time of life, will unite if the parts can be kept in contact, the keynote of union." It consequently follows, the more perfect the contact the more perfect the union.

Sir William Stokes lays down as the principles of treatment he advocates fixation, rest, and moderate extension. Rest, that is physiological rest, cannot be attained unless fixation, or, in other words, perfect coaptation, is secured. The means by which he proposes to accomplish this is by moderate extension, the very force he condemns as destructive of union by exciting antagonistic contest between mechanical and vital forces. This is at least illogical. Surely as soon as the desired position of the parts is obtained all destructive contest should cease. The error here lies in the non-recognition of the physiological value of muscular contraction.

Nature has provided herself with a reserve of muscular energy, the force of which only becomes apparent through accident or disease. It is this reserved energy which accurately adjusts the strength and density of bones to the power of the muscles. Under its influence absorption and deposition are carried on. It is only by restoring its marvellous influence that perfect physiological rest and functional activity can be secured. At the same time, it becomes a far

more effective means of fixation than any mechanical contrivance can be. To withhold or in any way to minimise its action impedes union.

The principles of treatment I advocate are reduction, coaptation, retention. The apparatus required to accomplish this should have the power of adjustment to the natural form of the limb throughout its entire length, and of preserving such form, so that when applied it is easily secured, and retentively holds the parts in perfect apposition.

Several forms of my apparatus are in the Museum of the College of Surgeons. It obtained "honourable mention" at the International Exhibition, 1883, the only one of the class so distinguished.—I am, etc.,

Blackheath, S.E., Oct. 31st.

W. H. B. WINCHESTER.

DIPHTHERIA ANTITOXIN AS A CULTURE MEDIUM FOR THE DIPHTHERIA BACILLUS.

SIR,—In the BRITISH MEDICAL JOURNAL of October 12th I was much exercised in my mind to learn that Drs. Wright and Semple, of Netley Army Medical School, suggest the use of diphtheria antitoxin as a culture medium for the diphtheria bacillus. I have not had an opportunity of verifying their experiment; but if it is a reliable one I wish to point out that it appears to upset my view of the value of the antitoxin as an antidote to diphtheria poisoning. I have always understood, although I may be open to correction, that the antitoxin contained a something—possibly a ferment—which, when introduced into the body of a patient suffering from the disease, effectually prevented the subsequent growth of the Klebs-Loeffler bacillus. If this is not so, what is the use of the injection?—I am, etc.,

Brighton, Oct. 14th.

W. A. HOLLIS.

CANCER STATISTICS.

SIR,—Will you allow me in the interests of accuracy to draw attention to Mr. Roger Williams's statistical methods as exemplified in the BRITISH MEDICAL JOURNAL of October 26th? I am not concerned at present with the question as to whether colliers are comparatively exempt from cancer, but merely with the trustworthiness of Mr. Williams's figures.

Mr. Williams remarks: "Of 250 men with cancer under my observation, 14 were agricultural labourers but only 1 was a collier." Such a statement is obviously valueless unless we know the proportion of agricultural labourers to colliers in the population from which Mr. Williams's patients were drawn. Failing this, the value of the above-quoted statement would be slightly increased if it were known in what district or districts the above-named cancer patients lived.

Leaving this minor point, we come to what may be described as Mr. Williams's chief dictum, a dictum of great importance if it will bear the test of facts. He states: "In London and its vicinity, where the wealth of the nation is clotted, there the cancer mortality is highest; and it is a significant fact that the mortality is highest of all in those parts of the metropolis where the well-to-do most abound." He arrives at this conclusion by calculating the deaths from cancer in proportion to the total population in each district. Thus stated, the deaths from cancer (taking two extreme cases given by Mr. Williams) were 1 in 2,885 in Bethnal Green as compared with 1 in 960 in Richmond. It would thus appear that "well-to-do, easy-going Richmond" had a mortality from cancer three times as great (for the same population) as that of Bethnal Green, where "the struggle for existence is hardest.....the general mortality highest, and where sanitation is least perfect."

Is this conclusion trustworthy? Its trustworthiness evidently depends on the age constitution of the two populations; for we know that 1 out of 21 men, and 1 out of 12 women who reach the age of 35 years, die eventually of cancer, while at ages below 35 the mortality from cancer is comparatively insignificant.

Now we have not before us the relative age constitution of the populations of Richmond and of Bethnal Green; but we know that a high birth-rate (continued for a long period like that of Bethnal Green) means a comparatively young population, while a low birth rate (like that of Richmond) means a comparatively old population. The birth-rate of Bethnal

Green is about 96, that of Richmond about 23 per 1,000 inhabitants. This makes no allowance for the effect of migration, Richmond being a favourite place of retirement for aged persons, and Bethnal Green receiving a steady annual influx of young (and therefore non-cancerous) lives.

It will be evident from these considerations that a very large proportion (possibly the whole) of the difference between the cancer mortality of Richmond and that of Bethnal Green is caused by age constitution of the two populations, and does not indicate any difference whatever in the true cancer mortality of the two districts.

Until Mr. Roger Williams presents us with a comparative statement of the cancer mortality in the contrasted districts, giving the death rate from cancer at each decennial group of ages per 1,000 living at the same group of ages, we must ask that his figures and the conclusions he draws therefrom shall be regarded as valueless.—I am, etc.,

Brighton, Oct. 25th.

ARTHUR NEWSHOLME, M.D.

ENTERIC FEVER IN INDIA.

SIR,—With reference to this disease which is at present occupying both the military and medical press, I would ask space to make the subjoined remarks.

Some twelve years ago I brought forward the results of personal inquiries and observations on this disease (Alexander Prize, 1881) tending clearly to the conclusion that the Indian disease was essentially the same as the European, clinically, pathologically, and etiologically, following the same laws, and doubtless due to the same one cause; the source of the virus being regarded as existent in the native haunts, and possibly some cases being lineally descended from other cases among Europeans through the excreta. The views then enunciated did not obtain acceptance, yet subsequent observation has but still further corroborated these deductions, and I suppose that now but few doubt the truth of the same.

Assuming the identical nature of the disease wherever met on this globe we have in the army in India, as explanatory of its presence, the marked susceptibility of the youthful soldier there sent, the insanitation of the native towns, accumulated results of ages, and probable transfer of disease among Europeans and half-castes from imperfect destruction of disease germs in the excreta. So long as the majority of the soldiers approximate 20 years of age it is difficult to perceive how the results can be otherwise than they are, other conditions remaining the same; extend the age period for India to 25 and decrease will ensue.

Again, we cannot isolate ourselves from the native community, nor can we annul, except after a lengthened period, the outcome of ages of sanitary neglect; but what we can do, while improving the native conditions, is to more strictly watch over the media of transfer of the disease—air, water, food—by augmented supervision and proper sanitary control, all food supplies (including drinks) being furnished solely from Government sources.

Again, we may thoroughly render harmless, by heat as I suggested, the excreta, and so oppose lineal descent among ourselves. In the near future, however, numerical reduction of the disease is only to be anticipated, not extirpation. Take the condition of the Ulsoor tank at Bangalore as reported in the *BRITISH MEDICAL JOURNAL* of October 5th. As it now is, so it has been for years past in spite of representation. What a condition for disease transference does this disclose!

The past history of this otherwise healthy and really European (climatically) station is a noted one touching enteric fever, and especially the locality adjoining the Horse Artillery lines; here the disease has run riot, and not limited to Europeans, time after time. Over and over again have troops contracted the disease passing up country after landing and on transfer from station to station, and in no small number of instances—especially in the hills—has the disease thus entered stations, rarely, however, effecting a lodgment.

One point forcibly struck me in wading through official documents, and that was the marked coincidence in incidence details of enteric fever and cholera among the troops—sometimes absent in stations, sometimes present—occasionally approximating an epidemic, though generally as isolated cases; sometimes restricted to a corps in a station, a company, even a bungalow or room, not uncommonly

contracted on the line of march; these features showing very clearly that the modes of access of each virus to the human frame were essentially the same and the surrounding conditions the same.

It is to the recognition by the higher military and medical authorities of the identity of the Indian to the European disease, with action on this line, and to the improved medical and sanitary status on the basis advocated by Mr. Ernest Hart that hope lies in the future. The authorities have not been without ample information in the past, but they have thought fit to ignore the work and reports of the executive rank; instead of action from within, it has been left to an independent outside source to parade the facts, and it is sincerely to be trusted that the outspoken, truthful remarks at the Public Health Section of the late British Medical Association meeting will not remain equally a dead letter.—I am, etc.,

Lee, Oct. 7th.

FRANCIS H. WELCH, F.R.C.S.,
Retired Surgeon-Colonel M.S.

IMMUNITY FROM THE EFFECTS OF SNAKE VENOM.

SIR,—In connection with the recent experiments and discoveries on the production of immunity to snake venom, communicated to the Royal Society of Edinburgh by Professor T. R. Fraser, I think the following experience will be of interest to the readers of the *BRITISH MEDICAL JOURNAL*, and perhaps throw some light upon the hitherto mysterious immunity enjoyed by the snake charmers of India and Ceylon.

In June, 1890, a Tamil snake charmer visited a village in the neighbourhood of my station (Mahurata) with two cobras (*Naja tripudians*), which he exhibited with more or less profit to himself. The exhibition consisted of the usual "tooting" on a bamboo flute, and of striking the cobra with the fingers and irritating it into raising its crest, expanding its hood, and biting the hand of the exhibitor, which is moved from side to side within striking distance of the cobra, so as to draw blood. The snake charmer then applies one of his "snake stones," apparently pieces of charred bone, to the puncture, and puts the snake back into his basket. In the case I am about to describe, a Singhalese man, aged about 45, who was evidently rather the worse for drink, witnessed the exhibition, and became fired with a desire to show that he could do as much as the snake charmer. He seized one of the cobras with one hand, and with the other he irritated the snake as he had seen the snake charmer do. The snake bit him on the back of the left hand. The snake charmer immediately applied one of his snake stones to the wound, but within three hours the Singhalese was dead. An inquest was held by the deputy-coroner of the district, and I was summoned and requested to hold a *post-mortem* examination. At the inquest the snake charmer stated that he could not explain why death should have resulted from the bite in the case of the Singhalese, notwithstanding the immediate use of his "specific" snake stone. He (the snake charmer) was bitten frequently every day by the snakes at his exhibitions. He would let both his snakes bite him in the presence of the coroner and myself. He thereupon took both snakes, one after the other, and went through the usual performance. I saw both snakes bite him on the back of his hand. He applied his snake stones to the puncture, and no change was observable locally or constitutionally either then or the next day, when he was taken before the police magistrate fifteen miles away and discharged.

I saw the deceased about two hours after death. There was a dark bluish ecchymosis surrounding two small punctures on the dorsum of the left hand. On incising into this, the subjacent tissue was found infiltrated with dark fluid blood, and the cellular tissue at the seat of the bite was softened and already disintegrating. The veins generally were tinged with dark fluid blood, and the thoracic viscera had the appearances usual in death from asphyxia. There were a few punctiform ecchymoses and extravasations on the pericardium and pleura. There was a strong alcoholic odour in the contents of the stomach.

The question that occurred to me at the time was why should one man succumb and the other be in no way affected? Both were bitten by the same snake, both were treated by the

same supposed miraculous snake stone. Professor Fraser's theory of immunity is the only one that can afford any explanation. How, then, did the snake charmer attain immunity? Snake charmers always try to get their snakes young. I cannot ascertain definitely whether they extract the poison fangs, but many people hold that view; but the fangs are supposed to grow again. The snake charmer, it is said, irritates the snake with a piece of stick round which a piece of rag is wound. The snake snaps at this and then empties its poison fangs, and this frequent ejaculation may be supposed to result in the secretion of a virus of minor intensity. The snake charmer, if bitten then, would receive into his tissues frequent doses of venom of feeble intensity, and thus in the course of time attain immunity against the venom of full intensity. This hypothesis is, in my opinion, the only one that can afford a solution to the problem as to why a snake charmer in India and Ceylon is immune against the venom of a snake which would be speedily fatal to an individual not so immunised.—I am, etc.,

HARRY BAWA, F.R.C.S. Edin.,
District Medical Officer.

Maturata, Ceylon.

THE MILK STANDARD.

SIR,—Certain statements that have appeared in the papers as to the results of analyses of milks during the late dairy show at the Agricultural Hall call for serious investigation, since if verified they cannot but reopen the whole question, and if allowed to pass unchallenged will certainly be used by the defence in future prosecutions. The standard hitherto usually adopted by analysts has been 87.5 water and 12.5 solids=9.3 solids not fat, and 3.2 fat. Some few, as Dr. Vieth, Mr. O. Hehner, and Mr. Bell, are inclined to think this estimate of solids other than fat too high, but it is generally believed, and admitted even by these gentlemen, that the fat usually exceeds 3.2, and indeed may in good samples be over 4 per cent.; but it is now alleged, on the authority of the judges, that many of the 126 cows entered for competition, including 9 out of 17 shorthorns, 4 redpolls, 2 cross-breeds, 2 Jerseys and 1 Guernsey, failed to show on analysis of their milk even 3 per cent. of fat. There can be no suggestion here of adulteration, since the animals would have been selected for their supposed value as milkers as well as for breed and beauty, but one would like to know the method of analysis employed, and whether the samples were taken from the morning or evening "meal" or both, and the whole well mixed. It can scarcely be imagined that the "fore milk" only was sampled, though such a gross blunder would account for anything, as Mr. Wynter Blyth found the "fore milk" of a Guernsey to contain only 0.85 of fat, while the "strippings" or milk last drawn gave 5.95, the mean of the whole volume being 4.

The allegation as to the shorthorns is of the most importance, since, on account of their hardness, they form by far the greater majority of the herds in the midland counties, which supply the London market with milk.—I am, etc.,

October 28th.

D. P. H.

"THE MARCHING POWERS OF OUR SOLDIERS."

SIR,—In a short article under the above heading published in the BRITISH MEDICAL JOURNAL of September 7th, you refer to the shoeing of the army as one of the defects leading to inefficiency, and though you rightly point out that it is the "fitting" which is mainly responsible, you do not, I think, quite do justice to the army boot itself. Continued personal experience has convinced me—and many others—that the "ammunition boot," as it is called, properly treated, is a most excellent article. I have walked and shot and marched many hundred miles in it, and know no better. Perhaps snipe shooting in the paddy fields of Burmah, varied by rough hill and jungle work in the dry season, may be accepted as a good test; and I have ammunition boots which have stood this test for two years, and are still in use. But they need intelligent treatment—and feet as well. As the boots are issued in sizes from 4 to 12, and of four different breadths for each size, it would be an abnormally difficult foot that could not be fitted. Two pairs should always be kept in actual use. They should be easy—easy enough to take two pairs of thick socks, for good padding is essential. They should never be

allowed to get dry or hard; should never be put in the sun or near a fire; and should be well rubbed with fat or dubbin while damp. In this state they can be blacked, but will not, of course, take a high polish. I lay great stress on plenty of padding in the shape of woollen socks; put on enough to fill the boot well and your feet will never suffer; if one thick pair is not enough, put on two or more; keep all your old merino socks to fill up with. Tommy never wears more than one pair (worsted), and those generally have holes; so have mine, but they are covered with other socks, and do not coincide. I used to suffer badly from corns, blisters, and tender feet; now twenty miles a day through mud and rough jungle will make no impression.

It takes three minutes to thoroughly rinse and squeeze two pairs of socks; they dry sufficiently in a night, but a day's sun improves them. Boots will dry in a night sufficiently if kept off the ground; five minutes suffices to grease boots well, and after greasing a few hours' sun is good. Fifteen minutes occasionally with needle and mending will keep socks going indefinitely. If this small expenditure of time and trouble is worth while for shooting, *a fortiori* it is worth while for campaigning or marching.—I am, etc.,

F. P. NICHOLS, M.B. Cantab.,

Shwobo, Upper Burmah, Oct. 6th.

Surgeon-Major, A.M.S.

THE D.P.H. (EDINBURGH CONJOINT BOARD).

SIR,—Perhaps my experience as a candidate at the above examination may prove useful to some of your readers who contemplate entering for the diploma. I would strongly impress on them the fact that a very full and complete course of special study in one of the Edinburgh laboratories is absolutely essential for success. No one who is in practice should attempt it unless he can have at least six months for special study. The practical examination in chemistry is searching—detection of metals and alkaloids in meat; estimation of carbonic oxide (CO) in air; whilst the bacteriological work necessitates a very thorough knowledge of processes and minutiae of laboratory work and ability to recognise cultures and micro slides. The paper in chemistry consisted of questions or estimation of amount of dissolved oxygen in water—a process, I believe, seldom used by our analysts—and a careful description of the steps necessary to detect chicory in coffee. Of 7 men only 2 passed. One had failed at a previous examination, and the other had devoted six months specially to the subjects for the first half of the examination. For the Final Examination only one candidate presented himself.

If this note prevents others from presenting themselves under the mistaken idea that the Edinburgh Colleges offer facilities to men engaged in private practice for obtaining a qualification in Public Health after a short course of study my object will be secured. I may mention I had at considerable inconvenience and great expense taken out a six-months course of work with the county analyst and entered under the old regulations.—I am, etc.,

October 10th.

A CANDIDATE.

OBITUARY

INSPECTOR-GENERAL SIR WILLIAM MACKENZIE, M.D.,
K.C.B., O.S.I.

INSPECTOR-GENERAL SIR WILLIAM MACKENZIE died at his residence in Gloucester Terrace, Hyde Park, on October 29th. Born at Dingwall, Ross-shire, in 1811, he graduated A.M. of King's College, Aberdeen, in 1830, M.R.C.S. Lond. in 1832, and entered the Madras Medical Service in 1835. He served with the Ellickpur Force of His Majesty the Nizam of Hyderabad's Army in 1841, and again in 1851 against insurgent Rohillas. He was Staff-Surgeon to the 1st Brigade Central India Field Force, under Major-General Sir Hugh Rose (Lord Strathnairn), during the whole of the campaign of 1857-58. He graduated M.D. of Aberdeen University in 1856. He was present at the following actions: Engagement with the enemy before Dhar, cavalry action at Chickliah, Siege of Dhar, operations at Mundarsore on the November 21st, 22nd, 23rd, and 24th, 1857; Siege of the Fort of Chanderee from March 6th till the

final assault on March 17th, 1858; general action of the Betwah on April 1, 1858; the assault on the Fort of Jhansi, April 3rd, and subsequent operations; the taking of Koonch, May 7th, 1858; the engagement at Goolowlee, May 23rd, 1858; capture of Calpee, May 22nd, 1858; engagement at Morar, June 16th, 1858; and subsequent attack on Gwalior, with pursuing column under General Napier (Lord Napier of Magdala), and engagement at Jowrah Allipore. He served as staff-surgeon to the Berar Field Force from November, 1858, to March, 1859, and was present at the engagement of Chichumbah on January 15th, 1859. For these services he was, in 1859, created a Companion of the Order of the Bath, and in 1867 he received the same rank in the Order of the Star of India; was appointed honorary physician to the Queen, 1857, and was advanced to the Second Class (Military) of the Order of the Bath on the occasion of Her Majesty's jubilee. He was Inspector-General of the Madras Medical Department, and retired in 1871. He wrote a treatise on the medical topography of Ellickpur and papers on the Indian materia medica. He also translated into Hindustani Gregory's *Practice of Physic* and Thomson's *Conspectus of the British Pharmacopoeia*. The funeral took place on Monday, November 4th.

The death is announced of Dr. WILLIAM PARTRIDGE MILLS, of Ipswich, at the age of 79. He was born at Lavenham, but went to reside at Ipswich very early in life. He was articled to the late Mr. W. Hamilton, surgeon, of Ipswich. He subsequently studied at Middlesex Hospital under Dr. Sweetman and Dr. Copland, where he carried off several prizes. He settled down in Ipswich after having passed his examination at the Royal College of Surgeons and at Apothecaries' Hall. He became L.R.C.P. in 1862, and graduated M.D. in the same year at St. Andrews. Dr. Mills had been for many years an alderman of the borough of Ipswich, and during the greater part of his life had been very closely connected with the benefit societies; not only was he prominently identified with Oddfellowship, but he took an equal interest in the sister Order of Forestry, his connection with which dated back nearly half a century. He was also a very ardent Freemason.

THE news of the sudden death of Mr. RICHARD BASIL MORLEY, L.R.C.P., L.R.C.S.Ed., at the early age of 43, when in apparently perfect health, came as a painful shock to his many friends in Leeds. He was the son of the late George Morley, for many years Lecturer on Forensic Medicine at the Leeds School of Medicine. Mr. Basil Morley began his medical career comparatively late in life. Of genuinely scientific tastes, he had found business uncongenial, and he entered as a student at the Leeds School of Medicine, where he was greatly distinguished amongst the men of his year. He qualified in 1883, and became resident officer at the Leeds Public Dispensary. He then began to practise at Chapel Allerton, Leeds, and during the past nine years had earned for himself a name for thoroughness of work and kindness to the poor. Mr. Morley was always a lover of Nature, and delighted especially in country work. The cause of his death was cardiac syncope. He had ridden out three miles into the country upon his bicycle to visit a poor patient, and sitting by her bedside, he suddenly fell forward from his chair, and almost immediately expired. The very large number of mourners who filled the churchyard at his funeral testified to the public esteem which he had won in his short professional life.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are Dr. Paul Schuette, formerly Medical Director of the Elizabeth Children's Hospital, Berlin, aged 48; Dr. Philipp Bertkau, Professor of Zoology in the University of Bonn; Dr. Janicke, Medical Director of the Augusta Hospital, Breslau; and Dr. Ferdinand Bauernfeld, formerly a well-known specialist in children's diseases in Vienna.

ERRATUM.—In the obituary notice of Dr. L. W. Andrews in the BRITISH MEDICAL JOURNAL, of November 2nd, p. 1199, it should have been stated that he was L.R.C.P. in 1869 (not 1866), and that he was a member of the Rugby Fifteen which won the Inter-hospital Cup in 1881 (not 1880).

NAVAL AND MILITARY MEDICAL SERVICES.

THE NAVY.

STAFF-SURGEON A. W. RUSSELL has been promoted to be Fleet-Surgeon, October 11th. He was appointed Surgeon, September 26th, 1894, and Staff Surgeon twelve years thereafter.

The following appointments have been made at the Admiralty: WILLIAM G. PECK, B.A., M.B., Surgeon, to the *Aden*, November 1st; HARRY SPICER, M.B., Surgeon, to the *Benson*, November 1st; HAROLD P. JONES, to the *Alexandra*, November 1st; ARCHIBALD MCKINLAY, Fleet Surgeon, to the *Howe*, November 2nd.

The retirement of Fleet-Surgeon GEORGE KELL, which appeared in the *London Gazette* of November 1st, is cancelled.

ARMY MEDICAL STAFF.

SURGEON-COLONEL G. MACDUFF, C.B., has been transferred from Allahabad to the Rawul Pindi District, to act as Principal Medical Officer on the staff of Major-General Moorsom, commanding a First Class District in the Punjab.

INDIAN MEDICAL SERVICE.

SURGEON-LIEUTENANT COLONEL W. M. COURTNEY, Bengal Establishment, is permitted to retire from the service from December 7th. He was appointed Assistant-Surgeon, October 1st, 1888, and became Surgeon-Lieutenant Colonel, October 1st, 1892. He served with the Duffa expedition in 1873-74; with the Burmese expedition in 1885-87 in medical charge of No. 18 Field Hospital with the 4th Brigade Upper Burma Field Force (medal with clasp); and with the Chin-Lushai Force, under Brigadier-General Symons, in 1889-90 as Senior Medical Officer in charge of the General Hospital (clasp).

Surgeon-General JAMES A. C. HUTCHINSON, M.D., Bengal Establishment, died at Bedford on October 26th, aged 57. He entered the service as Assistant Surgeon, November 26th, 1850; became Deputy-Surgeon-General, March 31st, 1877; and retired, with the honorary rank of Surgeon-General, September 28th, 1884.

ARMY MEDICAL RESERVE.

SURGEON-LIEUTENANT HEWARTSON CLARK, M.D., 1st Banff Artillery (Southern Division Royal Artillery), is appointed Surgeon Captain, November 2nd.

THE VOLUNTEERS.

SURGEON-LIEUTENANT COLONEL C. G. GREIG, 2nd Volunteer Battalion the Gordon Highlanders, has been awarded the volunteer officers' decoration.

Surgeon-Captain J. S. CARLETON, 1st Gloucestershire Artillery, and Surgeon-Captain W. M. VORRES, M.B., 2nd Volunteer Battalion the Royal Sussex Regiment, are promoted to be Surgeon-Majors, November 6th.

THE "RINGAROOMA."

In the *Times* of November 6th, the following appears among the appointments made at the Admiralty on November 4th:

"Captain.—W. L. H. Browne, to the *Ringarooma*, to date November 10th."

This announcement is interesting in connection with the case of Surgeon Francis J. Lea, who was dismissed the service last April after trial by court-martial on a charge of "insubordination and contempt." Mr. Lea attempted to put his commanding officer, Captain S. A. Johnson, on the sick list, as he considered him to be in an unfit state of health to be in command of the ship. We understand that the term of Captain Johnson's command would not in the ordinary course expire before the end of January, 1896.

MILITARY WAR TRAINS.

THE Canadian Pacific Railway, after many months of labour, have constructed at an enormous cost two special military or war trains, comprising 14 cars for men, 9 cars for cooking, 3 Pullman cars for officers, 2 cars for arms and stores, and 2 dining cars. The officers' cars are luxuriously fitted out, and contain state rooms, lavatory, smoking room, etc. Each train is composed of 11 cars and engine, and gives ample sleeping accommodation for 300 men and 15 officers, although over 100 more men could find room. The men's cars are well finished and furnished with modern improvements. The kitchen car has all the utensils of a large-sized hotel, and requires 6 cooks and 2 helpers. This one car can turn out over 1,500 meals a day. During a trip from Halifax to Vancouver on the war train 5,500 meals for officers and men are prepared. The Canadian Pacific Railway expect to cover the distance from the Atlantic to the Pacific in five and a-half days.

MILITARY ASSISTANT SURGEONS (INDIA).

AN addition has been made to Army Regulations, India, Vol. vi, Medical, as para. 278c. It runs as follows: Promotions in the place of a military assistant-surgeon dismissed the service or reduced to a lower rank or class by sentence of a court-martial, will be made into effect from the date on which the officer concerned ceases to draw pay of his former rank or class, as the case may be, which will be that following the day on which the order was communicated to him.

EXCHANGES A.M.S. AND I.M.S.

IT was announced some weeks ago that by Article 36 of the new Pay Warrant (new exchanges would be permitted between officers of the two medical services. A correspondent in the *Punch* of October 3rd states that the most important points to be considered are (1) a comparison between the pay of a surgeon-captain of from five to twelve years' service in the two branches, and (2) the difference in the two services of the pensions attainable after thirty years' service in connection with the

ordinary expectation of life on retirement and subsequent enjoyment of that pension. As regards the first, there is roughly, he says, a loss of Rs. 200 a month for seven years to the I.M.S. officer, or Rs. 10,800, or very nearly £1,000. In respect of the second item, the *Pioneer* correspondent states, taking ten years as the expectation of life on retirement after thirty years' service, there would be a loss of £200 a year for ten years to the I.M.S. officer, or £2,000 in all. So that, he sums up, it may be roughly stated that £2,000 would be a fair amount of compensation to be paid by the A.M.S. officer on exchange. It must be noted that exchanges by the new Pay Warrant are permitted only to A.M.S. officers under the rank of surgeon-major.

THE MEDICAL OFFICERS OF THE FRENCH ARMY AND THE MADAGASCAR EXPEDITION.

GREAT dissatisfaction appears to exist in the Medical Department of the French Army at what they consider to be the shabby way in which they are treated in the matter of the decorations of the Legion of Honour. It is said that when General Duchesne, after his terribly fatal though bloodless campaign in Madagascar, sent in his list of names for the Cross of the Legion of Honour, he "forgot" to include in it any officer of the medical staff. His attention having been called to this omission, he sent a second list, comprising the names of all the medical officers who took part in the expedition. This might, of course, be taken to mean that all those officers had deserved the decoration, but it is open to a less flattering interpretation. The fact is that throughout the campaign the work of the medical staff was hindered and crippled in the most deplorable manner by military pedantry and obstructiveness. It is the instinct of the military mind to make the task of the Medical Department as difficult as possible, and then to lay on it all the blame of the inevitable breakdown. Apart from the Madagascar expedition, French medical officers complain that the number of decorations falling to their share is much smaller than it used to be some thirty years ago. The matter is said to have attracted the notice of the late Minister of War, General Zurlinden, who, it is believed, was about to remedy this grievance had not the blind fury with the abhorred shears inopportunely slit the thin-spun thread of his official life.

The *Matin* publishes the diary of an officer who recently returned home from the campaign in Madagascar, showing that if the health of the troops was so deplorable, the fault lay in the first place with General Meisling, who believed that the fever was a myth. But a large part of responsibility also rested with General Duchesne, who, according to the officer's diary, constantly refused to allow the surgeons to take the prophylactic measures which they declared to be indispensable. Detachments were compelled to start without drugs, and the commanders disregarded all hygienic precautions, even on account of those who were already ill. The Pasteur filters, which have been so effectual in the army stations, were left behind. Aparent medicines were likewise wanting, and the result was that on September 1st the Director of the Medical Department reported that there were 8,000 men sick in the various hospitals. The number of deaths in the expeditionary force was 45 a day, and on September 30th the total number of deaths amounted to about 4,000.

THE CIVIL ARMY MEDICAL DEPARTMENT.

WE have received some very strongly worded letters which we deem it inadvisable to print, not from want of sympathy, but because we think everything that might be misconstrued should be avoided at the present juncture. They comment upon an incident at a late review by the new Commander-in-Chief at Dublin, which has caused much surprise and regret in military circles in Ireland. It is stated that a bearer company of the Medical Staff Corps saluted at the march past with "drawn swords," strictly according to regulation, upon which Lord Wolseley remarked they should not do so, as they were only a "civil branch" of the service. The *Irish Times*, in a leader on the subject, says: "It is clear, however, that the words were not employed in any public manner so as to have been in the ordinary way reported as a statement deliberately and intentionally made." We do not know whether they were so employed or not, but we deeply regret that they were used at all. We hope the Army Medical Service is entering on a better era under the new régime at the War Office, and entirely deprecate ill-advised speech or action which would increase tension or arouse ill-feeling. We do not know what changes, if any, may be in contemplation in the medical service, but have already expressed an opinion that, unless a very different policy is adopted from that pursued towards it in past years, the army may soon find itself without medical officers, "civil" or otherwise. The breach between it and the schools is rapidly widening, and unless bridged over in a conciliatory spirit, will soon be impassable for educated gentlemen. The solution of the difficulty will thus rest with the public and Parliament, and will pass from the control of the military authorities, which, for the sake of the army at large, would be very undesirable.

TITLES ON VISITING CARDS.

MEDICAL ETIQUETTE asks whether it is correct for an army medical officer to put M.D. on his card—thus: Surgeon-Major—, M.D.

Ans. It is a matter of taste. We have frequently seen cards thus: —, M.D., Surgeon-Major, Medical Staff. We know of no law, written or unwritten, on the subject.

ENTERIC FEVER AT BANGALORE.

BRIGADE-SURGEON-LIEUTENANT-COLONEL Wm. F. BURNETT (in charge of Station Hospital, Bangalore) writes: I will be glad if you will permit me to correct some inaccuracies in the statement made in the *JOURNAL* of September 21st in connection with enteric fever at Bangalore. The Ursur tank has not been used as a drinking water supply for the European troops since May, 1893; from that date the drinking water has been obtained from a large well south-east of British Cavalry Barracks, the water from which has invariably proved good and wholesome on analysis. Cleanliness in transit to barracks is carefully attended to. For some years past the drinking water for the European

troops at Bangalore has been boiled prior to distribution. Quarter-master-General's Memo., No. 1,235, of October 21st, 1889, sanctions extra fuel for the purpose. It will thus be seen that no change has been made during the year in the purification process with the exception that recently filtering has been discontinued by order and boiling alone resorted to. With the exception of the regrettable outbreak amongst young officers, the garrison has escaped fairly well this year. Up to date we have not reached half the number of cases we had last year, and the enteric season may now be considered practically over. The total number of cases amongst officers was five, with three deaths. In one instance the disease was contracted at another station.

THE PURCHASING POWER OF THE RUPEE IN INDIA.

VINCIT VERITAS (Punjab) writes: In the numerous letters which appear on the subject of the value of the rupee, your correspondents appear to take it for granted that in India the rupee has a purchasing power equal to 2s. We find in the Punjab that the smallest tradesman and pedlar make the depreciation of the coin an excuse for advancing the price of all their wares. The price of articles which form staple foods are in many cases the same as at home—namely, milk, 4d. per quart; butter, 1s. 2d. per lb.; flour, 2d. per lb.; sugar, 3d. to 4d. per lb.; potatoes, 1d. to 2d. per lb.; broad, 1d. per lb. Gao, topioca, and farinaceous foods are all nearly double in price; oatmeal six times the price. Fruit nearly the same as at home, and much inferior in quality and variety. Eggs are much cheaper, but being small and poor in quality are really as expensive; these foods are indifferently cooked; while with the poor, thin meat of India costs, with serving, as much, if not more, than at home. With servants and house rent at £200 a year, service in the "shiny" on the English rate of pay increases the weight of the liver and spleen at the expense of the purse.

BEARER COMPANIES.

SURGEON-CAPTAIN R. REGINALD SHERMAN writes: I feel certain that my friend, Brigade Surgeon-Lieutenant-Colonel Peter Goss, Welsh Border Volunteer Brigade, will agree with me that the bearer company of this brigade is on the strength of the 1st West of Scotland Rifle Volunteers. His letter, which appeared in the *BRITISH MEDICAL JOURNAL* of November 2nd, seemed to imply that a brigade bearer company need not be upon the strength of any battalion; but this is not so really, as will be seen by referring to Volunteer Regulations, Paragraph 36, which states that "the members of the bearer company will continue to belong to their own battalions." As to the examination of sergeants for proficiency certificates, it is true that they have to pass in the same subjects as corporals of the Army Medical Staff Corps for promotion. The regulation is a recent one as far as bearer companies are concerned. It has applied to sergeants of the Volunteer Medical Staff Corps for some time. The subjects of the examination are many, and include nursing, first aid, the management of wards, the practical use of the bath, ward and clinical thermometers, stethoscope and wagon drill, guard mounting, etc., so that it is a good test of the man's abilities.

REGIMENTAL STRETCHER BEARERS AND "FIRST AID TO THE WOUNDED."

INQUIRER writes: In the British Army two men per company in every regiment are ordered to be trained in rendering "first aid to the wounded." These men are to be placed under the medical officer with the regiment before a battle. They advance after the fighting line, and afford, so far as they can, aid to the injured, but they must not lose touch of their regiments. The bearer company then coming up deals with the wounded. Will any of your readers inform me how the "aid" expected to be rendered by the trained regimental stretcher bearers in the British Army is officially arranged to be rendered in the armies of France and Germany? Is it by trained members of the several regiments engaged, as with us, or by separate organisations like our bearer companies?

REDUCTIONS OF SURGEON-MAJOR-GENERALS.

INDEPENDENCE gives as his opinion that one of the reasons for the reductions in the highest rank is, that these officers are apt to be too outspoken on army sanitary reform. Having reached the top of the ladder, they have nothing more to gain by judicious reticence, and are therefore a thorn in the side of the War Office and the military hierarchy.

INDIAN MEDICAL SERVICE.

I. M. S. writes: May I correct a statement recently made in the *BRITISH MEDICAL JOURNAL* that "an Indian medical officer is not eligible for regimental duty till he has acquired a knowledge of the native language?" Although that is the regulation, he may be appointed to a native regiment on first arrival in India, and frequently is, owing to the paucity of medical officers. But he cannot draw the staff pay till he has passed the "lower standard" in Hindustani.

FORWARD writes on the same subject: Fancy an officer fresh from England having to examine and treat a sepoy with whom he cannot converse! It clearly indicates the officer must be entirely dependent on his native hospital assistant as an interpreter.

MEDICO-LEGAL AND MEDICO-ETHICAL.

PROSECUTION UNDER THE LUNACY ACT.

A VERY long letter has been received from Mr. F. R. Evans, the medical man concerned in the recent lunacy case at Birmingham. The chief portions of it are as follows:

"I did not personally plead ignorance as a defence. It would have been false, dishonourable, and disastrous for me to have done so. I was saturated with knowledge, not only of the Lunacy Acts 1800-91, but also with the equally-important Commissioners' and Lord Chancellor's statu-

tory rules, besides leading cases. I had had lunacy cases before, and I was not such an imbecile as to trifle with pains and penalties. What I did admit in my address to the learned Recorder was that I regretted I might have misconstrued the equitable significance of two words—a pardonable error even when committed by lawyers, but unpardonable by me.

"I received a lady patient on May 21st. As she was only suffering from simple mania, and not consequently, in my opinion—I am not, however, allowed an opinion or discretion by the recent decision—certifiably insane, I accepted her under the Act as a 'voluntary border.' I did not, therefore, require a licence, reception order, or agency order. Before the statutory twenty-four hours for reporting to the Commissioners in Lunacy had expired, the trustees under her late husband's will had filed a petition for an inquisition in the Court of Chancery. That is on May 22nd; no secrecy there. Now, if she had been 'so found' then, the Commissioners would have been fooled decidedly. Owing, of course, to the usual delays, they reached me through common law quibble.

"The case came before the Chief Clerk on the 24th. He was informed that she was at my house and under my care; being satisfied, he adjourned for a further report on her condition without making an order as permitted under the Act. On June 14th I sent up my affidavit and those of two other practitioners, certifying improvement. On the 17th, being again satisfied, he did not make an order, but duly appointed (sic) a chancery visitor, and adjourned to July 17th for further report. In equity, if not in law, she was clearly under chancery jurisdiction. She was 'pending,' being so found by inquisition. But still more, under the Lord Chancery's 2nd Rule, cases 'pending' are to be treated as 'so found,' and persons not being the owner are to be indemnified against loss. In consequence of this construction, I did not keep a register of medical attendance, register of seclusion, or furnish any of the returns required in the case of commissionary patients, for none such are required in the case of private chancery patients. The Masters in Lunacy do not require such minute formalities, only general information regarding the bodily and mental condition from the chancery visitor, leaving the physician discretion in the matter of treatment, as for his own sake he will do his best. On June 24th two practitioners visited on a magistrate's order, and certified that the patient was not under 'proper care and control.' In consequence of this she was removed to an asylum, where she died twelve days afterwards, I believe from exhaustion.

"The patient, aged 34, suffering from chronic mania, alcoholic gastritis, acute leucorrhoea, distention of left ventricle, with mitral murmur, was admitted May 21st. There were no signs of paralysis, meningitis, or ocular abnormalities, though the retinal vessels were slightly turgid, membrane of both eyes normal, urine free from albumen, sugar, and casts; specific gravity, 1.024. Pulse varying from 88 to 120, fairly normal in rhythm and tension; no signs of vascular degeneration. She would, and was allowed to, wander about the first night and next day, followed by an attendant. On 22nd developed 'acute mania'; on 23rd received whole bath, temperature 101°; wasted, weighed 135 lbs. nude, but great muscular strength. Confined in a barred single room, kept in bed by postural straps—namely, one across the chest and under the arms, which were quite free, the feet kept in the centre of ankle straps, which allowed limited motion, quite unobscured of their presence, and consequently did not fret or struggle to get free. No medicine or stimulants given throughout. Soda water first two days, afterwards to 20 ounces milk, 6 eggs, and 3 ounces cornflour in a sweet fluid mixture, poured into the pharynx and swallowed automatically owing to distention. Rapidly passed into mania gravis, and on May 24th into acute delirium. Bronchitis cured by inhalations; dilatation and murmur increased.

Here follow remarks on acute delirium, and on the objections the writer has to the 'possible alternatives to postural straps' in this particular case; and a few more clinical notes.

"Professional Discretion. This is a matter of supreme importance to the general practitioner. The Birmingham Recorder has decided that I had no right to use mechanical restraint, it is not being necessary for medical purposes under Section 49. Although I from the dock emphatically affirmed that in my discretion rest was a medical treatment and was absolutely necessary to avert death, it mattered not. Although counsel cited 'authorities' it mattered not, the witness disagreed with all, and no more authorities were permitted to be cited.

"Now, if I have not any discretion of my own, from whom must I get it, especially on an emergency? Must I ask the poor father of the child suffering from diphtheria for a stamped deed of indemnity against prosecution, lest some practitioner who only believes in intubation may witness against me, or the man who advocates antitoxin only do likewise? Or must I demand the opinions of all the specialists around, requiring their fee in advance, lest some of them may appear against me in case I should be indicted? Or shall I proclaim myself a coward by abandoning the case? I know not; medical witnesses, in my experience, act the part of prosecuting counsel.

"Now in my 49th year, I can truthfully assert that I have never shirked any case in surgery, midwifery, or gynaecology to which I was summoned. I fortified myself to meet each emergency. I never contravened the ethical code in the slightest degree. Then what is this prosecution? Shall my hair be turned white and the flesh worn off my bones by disturbed dreams of death and visions of prison cells? Must I at 40 abandon the profession in despair, with my youth gone, my spirits broken, and a financial wreck?"

ECONOMICAL FISCALS.

The following paragraph recently appeared in a Glasgow newspaper concerning the attempt of the Procurator-Fiscal to conduct the fatal accident inquiries with the minimum of expense for professional witnesses:

"In an inquiry held the other day the subject had died in the infirmary, but instead of summoning the doctor who had signed the death certificate, the nurse who had attended the man was put into the box. 'What was the cause of death?' queried the Fiscal. 'I don't know,' was the reply. 'Oh, but the man died, didn't he?' 'Yes.' 'And you attended him?' 'Yes.' 'And yet you don't know what he died of?' 'No.' 'Did the doctor not say what he died of?' 'No.' 'Such was the turn the examination of the nurse took. I cannot say that she had been

primed beforehand by the doctor, but she couldn't have served the profession better if she had."

Dr. D. D. Mackintosh writes us on this subject that a like case has recently occurred in his practice. On October 4th a number of men were working at an excavation when one of the sides fell in, burying a man. When called, Dr. Mackintosh found that the man had been killed, the cause of death being fracture of several ribs which had also pierced the lung, fracture of the right thigh bone, and fracture of the spinous process of the fourth dorsal vertebra. The local police surgeon attended also, and requested from him a report on the cause of death, which he gave. At the subsequent inquiry, Dr. Mackintosh was not called as a witness. One of the labourers, after giving his own evidence, was recalled and examined as to the cause of death, when he said that the doctor had given it as his opinion that death was due to the back being broken. Dr. Mackintosh sent in a demand for a fee of one guinea to the Fiscal for his report, who replied that as he had not been called at his instance the fee could not be paid. Dr. Mackintosh asks what practitioners should do when a like case occurs again?

TOUTING.

H. T. H.—Assuming that our correspondent's statement fairly represents the facts, there can be no doubt that the conduct of H. in advertising his testimonials among A's patients, and in the neighbourhood generally; also in toutting for patients and seeking to undercharge A, and in inducing cottagers in various villages to sell for him on commission, pills, castor oil, etc., constitutes a grave breach of medical ethics, the rules of which he will do well to study and to practise, otherwise such derogatory proceedings cannot fail sooner or later to recoil upon himself, and deservedly so.

M.B. CANTAN.—Although the courtesy of the faculty and of the public (outside of the University precincts) have for a long period awarded the title of "Dr." to M.B. graduates, it is deemed in better taste to avoid such prefix on their visiting cards and doorplates. If, however, it is desired that the degree should appear, M.B. would be a suitable inscription.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

The Registrar-General has just issued his return relating to the births and deaths registered in England and Wales during the third, or summer, quarter of this year, and to the marriages during the three months ending June last. The marriage-rate was equal to 16.0 per 1,000 of the population, and exceeded the average rate in the corresponding periods of the ten preceding years.

The births registered in England and Wales during the three months ending September last numbered 321,734, equal to an annual rate of 39.2 per 1,000 of the population, estimated by the Registrar-General to be nearly thirty and a-half millions of persons in the middle of this year. This rate last quarter showed a recovery from the exceptionally low rate in the third quarter of last, but with this exception it was the lowest birth-rate in the corresponding period of any year since 1871. The birth-rates in the several counties ranged from 22.5 in Rutlandshire, 22.8 in Westmorland, and 24.0 in Huntingdonshire to 34.6 in Monmouthshire, 35.0 in Staffordshire and in South Wales, and 36.0 in Durham. In thirty-three of the largest English towns the birth-rate last quarter averaged 31.1 per 1,000, and exceeded by 3.9 per 1,000 the general English rate. In London the birth-rate was 30.4 per 1,000, while it averaged 31.5 in the thirty-two provincial towns, among which it ranged from 24.1 in Huddersfield, 24.4 in Halifax, and 25.2 in Brighton to 35.3 in Gateshead, 35.3 in Salford, and 36.1 in Liverpool.

The births registered in England and Wales during the quarter ending September last exceeded the deaths by 8,348, this represents the natural increase of the population during that period. It appears from returns issued by the Board of Trade that 2,120 emigrants embarked during last quarter for places outside Europe from the various parts of the United Kingdom at which emigration officers are stationed. Of these, 40,007 were English, 8,019 Scotch, 16,691 Irish, and 30,123 of foreign origin. Compared with the averages in the corresponding periods of recent years, the proportion of English emigrants showed a decrease, while those of Scotch and Irish emigrants showed an increase.

During the third quarter of this year the deaths of 124,000 persons were registered in England and Wales, equal to an annual rate of 15.4 per 1,000 of the estimated population; this rate was 0.7 per 1,000 above the mean rate in the corresponding periods of the ten preceding years. The lowest county death-rates last quarter were 11.6 in Rutlandshire, 11.7 in Somersetshire and in Westmorland, and 11.8 in Devonshire; while the highest rates were 19.7 in Northumberland, 21.0 in Durham, 22.2 in Lancashire, and 25.5 in the East Riding of Yorkshire. In the urban population of the country, estimated at about twenty and a-half millions of persons, the rate of mortality during the quarter under notice was 18.9 per 1,000; while in the remaining and chiefly rural population of nearly ten millions it was 14.4 per 1,000. These rates were respectively 1.0 per 1,000 above, and 0.1 per 1,000 below, the mean rates in the corresponding quarters of the ten preceding years. Among thirty-three of the largest English towns the mean death-rate was 2.2 per 1,000; in London the rate was 18.6 per 1,000, while it averaged 17.3 in the thirty-two large provincial towns, and ranged from 12.5 in Grays, 14.4 in Bristol, 15.0 in Huddersfield, and 18.4 in Swansea, to 23.0 in Sunderland, 24.1 in Wolverhampton and in Preston, 24.2 in Salford, and 25.2 in Liverpool. In sixteen other large towns, with an estimated aggregate population of about three and a-half millions, the mean death-rate was 18.4 per 1,000, or 1.6 per 1,000 below the mean rate in the thirty-three large towns.

The 134,500 deaths registered in England and Wales during the three months ending September last included 18,118 which resulted from diarrhoea, 3,500 from measles, 1,500 from diphtheria, 1,800 from whooping-cough, 1,400 from "fever" (including typhus, enteric, and ill-defined forms of "fever"), 1,200 from scarlet fever, and 99 from small-pox; in all, 26,518 deaths were referred to these principal zymotic diseases, equal to an annual rate of 1.50 per 1,000, against an average rate of 2.73 in the corresponding quarters of the ten preceding years. The mortality from diphtheria and from diarrhoea showed an excess, while that from scarlet fever, whooping-cough, and "fever" was below the average. Of the 99 fatal cases of small-pox registered last quarter in England and Wales, 31 occurred in London, 17 in Oldham, 5 in other parts of Lancashire, and 21 in the West Riding of Yorkshire.

The rate of infant mortality in England and Wales last quarter, or the proportion of deaths under one year of age to registered births, was equal to 301 per 1,000, which exceeded the mean proportion in the ten preceding corresponding quarters by 41 per 1,000, owing to the fatal prevalence of summer diarrhoea. In London the rate of infant mortality was 229 per 1,000, while it averaged 273 in the thirty-two large provincial towns, among which it ranged from 141 in Bristol, 167 in Huddersfield, and 168 in Halifax to 305 in Preston and in Hull, 367 in Wolverhampton, and 369 in Burnley.

The mean temperature of the air during last quarter at the Royal Observatory, Greenwich, was 52° 35', and was 2.7° above the average in the corresponding quarters of 124 years; the mean temperature showed an excess of 1.0° in July, 1.3° in August, and of 5.7° in September. The rainfall during the quarter amounted to 8.46 inches, which was 0.83 of an inch below the average.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,542 births and 4,464 deaths were registered during the week ending Saturday, November 2nd. The annual rate of mortality in these towns, which had been 19.1 and 19.7 per 1,000 in the two preceding weeks, further rose to 21.9 last week. The rates in the several towns ranged from 12.3 in Croydon, 14.2 in Huddersfield, and 15.0 in Halifax to 30.8 in Salford, 33.1 in Blackburn and 35.5 in Liverpool. In the thirty-two provincial towns the mean death-rate was 22.4 per 1,000, and exceeded by 1.2 the rate recorded in London, which was 21.2 per 1,000. The zymotic death-rate in the thirty-three towns averaged 2.9 per 1,000; in London the rate was equal to 2.8 per 1,000, while it averaged 3.0 in the thirty-two provincial towns, and was highest in Burnley, Salford, and Blackburn. Measles caused a death-rate of 1.8 in Wolverhampton, 3.0 in Salford, and 9.0 in Blackburn; scarlet fever of 1.0 in Birkenhead and in Salford; whooping-cough of 1.4 in Bradford; and "fever" of 1.7 in Sheffield, 2.0 in Salford, and 2.7 in Sunderland. The 108 deaths from diphtheria in the thirty-three towns included 72 in London, 7 in Birmingham, 6 in West Ham, and 4 in Manchester. Three fatal cases of small-pox were registered in West Ham, and 1 in London, but not one in any other of the thirty-three large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital, which had been 159, 119, and 114 at the end of the three preceding weeks, had further declined to 104 on Saturday last, November 2nd; 29 new cases were admitted during the week, against 9, 7, and 14 in the three preceding weeks. There were 2,041 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, against 2,697, 2,438, and 2,635 at the end of the three preceding weeks; 215 new cases were admitted during the week, against 332, 241, and 269 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday last, November 2nd, 822 births and 501 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 18.7 and 18.9 per 1,000 in the two preceding weeks, rose again to 20.5 last week, but was 1.4 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 17.1 in Leith to 29.5 in Paisley. The zymotic death-rate in these towns averaged 2.4 per 1,000, the highest rates being recorded in Aberdeen and Greenock. The 288 deaths registered in Glasgow included 11 from whooping-cough, 10 from diarrhoea, 5 from scarlet fever, 4 from "fever," and 3 from diphtheria.

THE HEALTH OF MIDDLESEX.

THE annual report upon the health of the administrative county of Middlesex for the twelve months ended March last, prepared by Dr. Sykes, shows that the birth-rate was 28.7 per 1,000 in the urban districts and 26.2 in the rural districts. The total for the county was 28.5, and for England and Wales 26.6; while the deaths were 12.7 for the county against 16.6 for the whole country. The highest death-rate was in Edmonstone, where it was 17.7, but this included the deaths in two workhouses within the district. The lowest was in Ealing, 9.6. Dealing with the infectious diseases hospitals, Dr. Sykes says one-half of the county is unprovided with them. From the figures supplied it would seem that only 12 children born in the county during the year were unvaccinated. The laundries in the county are numerous, but Dr. Sykes says only 8 out of 32 districts appear to give them any attention, and in only half of the number of districts are the bakehouses more or less regularly visited, although such inspections are of great importance. The same thing to a large extent applies to dairies, cowsheds, and milk shops. Referring to the water question, Dr. Sykes, who is the medical officer of St. Pancras, says: "As illustrating one of the dangers of the intermittent supply of water, Dr. Ridge (Enfield) records that there have been some complaints of the water as delivered. The water supply being intermittent, sewage-contaminated water was able to get into a defective pipe, and was distributed when the water was turned on. This revealed a great cause of waste: the pipes had been in the earth twenty years, and there can be no doubt there are many others in the same condition, which accounts for many of the complaints of the supply of muddy water. It is desirable that water meters should be affixed to the

main at suitable points, which would at once show when and where waste was occurring, and would thus save repay their first cost." At Uxbridge, which is served by one of the numerous water companies, Dr. Rymer says many of the service pipes have been laid forty years, and Dr. Fletcher Little says cisterns require frequent inspection and cleansing, and cleaning four times a year would prevent them getting into an insanitary state. "Chronic ill-health is often traceable to this cause. All drinking water should be drawn direct from the supply pipe as it enters the house from the mains." On this, Dr. Sykes says, "may be added the urging of the provision of a constant service." Dr. Dodsworth, of Chiswick, concurs in this view, and Dr. T. Watson, of Tottenham, complains that the water companies (the East London and New River) have cut off supplies for the non-payment of rates, and this caused the houses to become unfit for habitation and a danger to the neighbourhood.

MILK TYPHOID.

A REPORT by Dr. John T. Wilson, Medical Officer of Health for Lanarkshire, dated October 21st, regarding the epidemic of enteric fever at Shettleston, has just been published. Dr. Wilson states that the present prevalence of enteric fever in Shettleston—twenty-five cases have been reported up till October 20th—exceeds that of previous years. The thirty-five cases occurred in twenty-three houses, the incidence being greater in the newer tenement houses than in the old cottage class of property. Up till October 5th the features of the outbreak were those presented by the usual autumnal prevalence of the disease, although occasionally associated with sanitary defects. But the sudden increase in the ensuing fortnight, and especially the fact that four members of one family took ill on the same day and two members of another family on another day, pointed to a common cause, such as contaminated water or infected food. In eight families with fifteen cases it was found that the milk had been obtained from a dairy situated in the centre of Shettleston. From this dairy, which supplied sixteen families in the vicinity regularly with milk, a case of enteric fever was notified on September 28th, and upon the usual inquiry being made by the sanitary inspector it was found that the patient had been ill since September 14th, and nursed during that time by one of the family, who also took part in the dairy work, attending milk vessels, etc. The sanitary inspector at once advised the immediate stoppage of the dairy business, which the owner willingly carried out. Of the sixteen families supplied by the dairy up till September 28th, seven, or over 40 per cent., have now suffered from the disease, as well as two other inmates of the dairy itself who also consumed the milk. These facts, Dr. Wilson says, seem to implicate this dairy as a probable agent in disseminating the disease. He further points out that a case has occurred in a family where two of the members were employed in a milkshop. The sale of milk here was stopped a few days after the date of attack. The disease, the medical officer further says, has in most cases been of a mild type, but two deaths have already occurred.

EDINBURGH AND LEITH AGAIN.

THE petition by the Lord Provost, magistrates, and Town Council of Edinburgh for warrant to erect a temporary hospital has again come before the Leith Dean of Guild Court. As was reported in the BRITISH MEDICAL JOURNAL at the time, the Dean of Guild Court rejected the petition in August, on the ground that the petitioners had no right to erect and administer an hospital for infectious diseases within the bounds of the Burgh of Leith. The Edinburgh Corporation appealed to the Court of Session, and the Judges of the First Division sent the petition back to the Dean of Guild Court for procedure, and added that the Court had no right to concur upon objections which were not before them. At the meeting this week the Provost of Leith again came to the front, and said: "This is no doubt an important case, and seeing that three of our number demit office to-night, I would propose to the Court that we should continue this case for another fortnight. By that time it will be before the Town Council. They have never heard of it, unless from the papers, which have not stated the case very much in the way that was in accordance with what we thought. By next Court the Town Council will consider the matter, and give the Dean of Guild Court authority to oppose this. I personally would oppose it to the bitter end; that is my opinion about it." In vain did the agent for the Corporation plead that this was an extraordinary mode of transacting business. The Provost went on: "I will give you my reasons: I hold this is illegal. And further, I am not going to argue the case with you. You are not going to come here and ram this case down our throats."

ZYMOTIC MORTALITY IN LONDON.

THE accompanying diagram shows the prevalence of the principal zymotic diseases in London during each week of the third quarter of the current year. The fluctuations of each disease and its fatal prevalence as compared with that recorded in the corresponding weeks of recent years, can thus be readily seen.

Small-Pox.—The deaths referred to small-pox, which had been 5 and 10 in the first two quarters of the year, further rose to 31 during the three months ending September last, and were 12 above the corrected average number in the corresponding periods of the ten preceding years, 1885-94. Of these 31 deaths, 6 belonged to Camberwell, 4 to Whitechapel, and 2 each to Strand, Shoreditch, Bethnal Green, Lambeth, and Plumstead sanitary areas. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 16, 54, and 33 at the end of the three preceding quarters, had increased to 227 at the end of September last; 583 new cases were admitted during last quarter, against 79, 155, and 92 in the three preceding quarters.

Measles.—The fatal cases of measles, which had been 300 and 504 in the two preceding quarters, further rose to 753 during the three months under notice, and were as many as 246 above the corrected average number. Among the various sanitary areas of the metropolis measles showed the highest proportional fatality in St. Pancras, Holborn, Clerkenwell, St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Bermondsey, and Camberwell.

Scarlet Fever.—The deaths referred to this disease, which had been

deceased in consequence of the animal having suffered from tuberculosis. The number of carcasses culled by medical officers of health and inspectors of nuisances rose from 1,200 in 1901 to 2,500 in 1904. In 1904 100 carcasses, and 200,000 carcasses were condemned by justices. The number of carcasses so condemned in consequence of the animal having suffered from tuberculosis rose from 100 in 1901 to 100 in 1904. The figures, however, in many cases show that the carcasses were destroyed without being taken before the justices, and that some of the carcasses so destroyed were those of animals which had suffered from tuberculosis. Some local authorities have furnished information as to carcasses voluntarily surrendered by owners and subsequently destroyed, and places of meat, not being whole carcasses, which had been seized and condemned.

WATERBORNE TYPHOID AT TORONTO.

A typhoid fever epidemic is threatened in Toronto. Some time ago the water conduits burst, and since that time the city has been without pure water. The effect is now apparent from the returns of the local Board of Health. For the first nine days of the present month 77 cases of typhoid fever were reported, against 50 in the whole month of October last year and 27 cases in October, 1903. There are a large number of patients at the different hospitals: At Grace Hospital there are 38, at St. Michael's 20, and at the General 10.

HAMPSHIRE AND VACCINATION.

At the meeting of the Hampstead Board of Guardians on October 31st, Mr. J. S. Fletcher, J.P., L.C.C., the chairman, called attention to the unsatisfactory position in which Boards of Guardians are placed by reason of the delay in the publication of the report of the Royal Commission. The following resolution was passed: "That the delay in the publication of the final report of the Royal Commission on Vaccination encourages persons who are opposed to vaccination to disobey the law, and is embarrassing to Boards of Guardians, inasmuch as it is their obvious duty to prosecute transgressors of the law while it is being the subject of parliamentary inquiry as to its usefulness or necessity." This was carried, and it was further resolved that copies of the resolution be forwarded to the Home Secretary, the President of the Local Government Board, and to each of the Metropolitan Boards of Guardians.

THE NEWCASTLE PORT SANITARY AUTHORITY AND DR. ARMSTRONG.

At a meeting of the Newcastle-on-Tyne Port Sanitary Authority, held on October 29th, the clerk read a letter from Dr. J. F. Armstrong, stating that he had noticed in the papers the resignation of Dr. Henry Armstrong, and as his deputy he begged to tender his resignation also. Alderman W. D. Stephens, J.P., moved that the resignation of Dr. J. F. Armstrong be accepted, but that he be asked to act in his present position until the end of November. The motion was agreed to. The adoption or otherwise of the minutes of a committee consisting of the whole board recommending the acceptance of Dr. Henry Armstrong's resignation of medical officer of health was then considered. Mr. Kirby moved, and Mr. T. D. Marshall seconded, that the resignation be accepted, and that the board expressed its high appreciation of his past services, and recognised his uniform kindness in the performance of his duties. Dr. Adam Wilson spoke of Dr. Armstrong's great services to the town, and said that it was not only a local but a national misfortune, for they could not afford, without great loss, to part with the services of such a medical officer of health as Dr. Armstrong. It was decided that Dr. Armstrong be asked to continue his services until December 31st. The Clerk (Mr. R. Sheridon Holmes) in answer to questions, said the salary of Dr. Armstrong had been £170, and the salary of the assistant was £50. It was agreed on the motion of Alderman Hindmarsh that the authorities advertise for a medical officer of health at a salary of £200 a year, the gentleman appointed to live in the borough of Tynemouth or South Shields. It was moved that the House Committee meet to decide the duties of the medical officer, and this was seconded and carried. The Chairman said before the meeting separated he was sure they all regretted that Dr. Armstrong had felt it his duty to withdraw from the position he had held. He thought Dr. Armstrong was a man of so much experience that they might ask him to accept the position of consulting medical officer to the authority, at an honorarium of, say, 50 guineas, just to cover expenses which he might be put to if called upon. In case of an outbreak of cholera, etc., where they were required to spend a good deal of money, they would find Dr. Armstrong's services very valuable to them. Alderman W. D. Stephens seconded. He said he had the greatest respect for Dr. Armstrong, and felt the greatest regret that he had seen fit to withdraw. On the suggestion of Alderman Hindmarsh, the Chairman agreed to withdraw his motion in order that it might be placed on the agenda for the next meeting.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE.

BOTANY.—Dr. H. Marshall Ward, F.R.S., has been elected to the Professorship of Botany vacant by the death of Professor C. C. Baskin. Mr. F. P. Blackman, Demonstrator in Botany, has been elected to a Fellowship in St. John's College.

STATE MEDICINE.—The Graduate report that the increasing importance of bacteriology in its relation to public health has necessitated an extension of the time devoted to the subject in the half-yearly examinations, and the appointment of a fifth examiner specially conversant with it. The two parts of the examination in October and in April will in future be held in successive weeks. At the last April examination there were 22 candidates, of whom 13 passed; and in October there were 24, of whom 14 passed. Thirty-one successful candidates received the University diploma in Public Health during the year. The fee for each part of the examination will in future be six guineas instead of five, except in the case of candidates who have already been admitted to the examination.

MUSEUM OF ZOOLOGY.—Lord Tankerville has received the thanks of the University for his present of the skeleton of a Chillingham bull.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The following gentlemen, having conformed to the By-laws and Regulations and passed the required Examinations, have been admitted Licentiates of the College:

Abbott, J. E., Leeds
Aali, P. H., Leeds
Ashwin, R. H., Guy's
Austin, J. D., Manchester
Barnes, T. A., St. Bartholomew's
Beecham, A. H., St. Bartholomew's
Bell, T. D., University College
Bernard, A. M. M., Guy's
Best, W. H., London
Bodman, J. R., St. Bartholomew's
Boswell, E. B., Guy's
Brewer, T. A., Cambridge and St. Bartholomew's
Bryson, A. J. H., St. Bartholomew's
Bryson, J. M., St. Thomas's
Brown, R. C., Melbourne and Westminster
Bull, H. A., St. Thomas's
Campion, G. K., University of Cambridge and Guy's
Campbell, A. J., St. Thomas's
Carr, A., Birmingham
Carr, W. A., Guy's
Cassidy, G. A., St. Bartholomew's
Chad, G. A., Oxford and St. Thomas's
Clark, R. F., Guy's
Connell, A. M., University College
Cook, A., Oxford and London
Cook, M. A., St. Bartholomew's
Coulson, F. J., University College
Cox, H. F., King's College
Crane, K. E., University College
Crosby, A. H. P., Middlesex
Crowley, A., Manchester
Cusack, P. J., Dublin
Dawson, B. L., Lahore and University College
Dawson, A. D. P., University College
Dun, R. C., Edinburgh and Borneo
Dyball, B., St. Thomas's
Eames, C. W., Edinburgh and Leeds
Evans, E. L., Cambridge and St. Bartholomew's
Fairbairn, J. B., Oxford and St. Thomas's
Farmer, W. H., St. Bartholomew's
Fincham, E. C., St. Bartholomew's
Flaming, W. L. R., Westminster
Fletcher, R. H., University College
Flower, A. F. A., St. Bartholomew's
Frazer, W. D., St. Thomas's
Ganner, J., Birmingham
Genge, G. F. S., Westminster
Giblin, W. W., St. Bartholomew's
Gilmour, R. W., St. Bartholomew's
Gross, C. F., King's College
Hardcastle, W., Charing Cross
Hardy, F. S., Sheffield and University College
Harris, N. MacL., Toronto
Hartley, T. S., Leeds
Hay, J., Liverpool
Hayden, G. A. T., London
Henderson, H., Guy's
Henderson, E. H., Leeds
Hewson, H., Guy's
Hill, E. G., St. Mary's
Holme, C. W., Edinburgh
Hors, J., Guy's
Hubert, W. A., St. George's
Hussey, A. H. M., Guy's
Hussey, L., University College
Hussey, F. H., Edinburgh and University College
Jervis, R. D., Middlesex
Kear, F. W., St. George's
Lambert, T., University College
Lawrence, A. S., Middlesex
Lefson, P. S., St. Mary's
Leon, J. T., St. Mary's
Lornie, E. A., Newcastle, and St. Bartholomew's
Lyon, C. H. B., Madras, and Guy's
Lyon, P., Guy's
Lyon, W. T., Bristol
Macdonald, A., Cambridge and Leeds
Macdonald, N. H., Edinburgh
Maddox, F. B., St. Bartholomew's
Manby, W. F., Cambridge, and King's College
Marshall, G. S., M. D., Guy's
Martineau, A. J., St. Thomas's
Mayne, B. J., Middlesex
Miller, G., St. Bartholomew's
Muggeridge, F. C. H., London
Murray, J. H., University College
Myrle, G. V., Leeds, and St. Mary's
Nott, H. W., Liverpool
Nuttall, A. W., Birmingham
Ormerod, E. W., Bristol
Ormerod, D., London
Pearce, J. N., Middlesex
Penny, W. R., Westminster
Pepper, H. W., Birmingham
Perkins, G., Madras, and University College
Perry, W. D., Middlesex
Pritchard, H. W., Manchester
Rawson, A. C., Cambridge and St. Mary's
Rawson, W. F., Leeds
Rees, D. G., Charing Cross
Rogers, A. A., St. Bartholomew's
Rundell, C., St. Mary's
Savin, L., Middlesex
Sears, A. E., London
Shepley, F. W., St. Bartholomew's
Shepley, H., St. Thomas's
Shipp, S. L., University College
Simpson, C. E., St. Thomas's
Smith, F. A., St. Bartholomew's
Sparrow, H. R., Liverpool
Stonhouse, H., Leeds
Stuart, W. J., Guy's
Thornton, F. R., St. Thomas's
Trotter, R. H., Leeds
Tyson, W., Cambridge and Guy's
Wakefield, C. F., Guy's
Watson, F. J., Cambridge and St. George's
Wilde, A. N., St. Bartholomew's
Williams, F. D. A., M., Bristol
Willmore, W., Birmingham
Wilson, H. H., Bristol and Birmingham
Wolfenden, H. C., Birmingham
Wood, R. M., King's College
Worthington, J. V., London

* These candidates have not presented themselves under the regulations of the Examining Board.

ERRATUM.—The name of Mr. A. W. N. Auden was accidentally omitted from the pass list for M.B. and Ch.M. of the University of Edinburgh in the BRITISH MEDICAL JOURNAL of October 29th.

HOSPITAL AND DISPENSARY MANAGEMENT.

ROYAL ALBERT ASYLUM, LANCASTER.

FROM the report presented to the annual meeting of this institution, held on October 26th at Southport, it appears that there were in the asylum on June 30th 649 patients (370 males, 179 females), and that the average number resident during the preceding twelve months had been 540. Dr. Tedford Smith, the medical superintendent, states in his report that during the year 17 deaths had occurred, and that of these 70 per cent. were due to tuberculous diseases. The death-rate calculated on the average number resident was 3.14 per cent., a percentage approximating very closely to the average annual mortality since the opening of the institution twenty-five years ago. The general sanitary condition of the

asylum and its various branches had been good, and there had been an entire absence of infectious disease. The hospital infirmary had been extended by the addition of isolation wards, and the average number of patients under treatment there had been about 24. Prescriptions of kind in most cases accompanied by food and drink. And as for the ordinary nursing, it is impossible to say that it is better than in the past, even for those suffering from ordinary ailments, whilst in time of epidemic infectious both for isolation and quarantine are indispensable. Dr. Telford, on the question of the desirability of dealing with the epileptic patients in a special part, their association with the other inmates being a matter of difficulty and even danger. He concludes an interesting report by testimony in favour of the surgical treatment of sporadic cretinism, and advises to that of microcephaly by craniotomy, referring to results in cases he has had under observation for some years.

Mr. John Balfour, Chairman of the Royal Albert Asylum and of the Lancashire County Council, in moving the adoption of the report, stated that it was computed that in the northern counties there were 2,000 weak-minded persons under 30 years of age, whilst their institution, the only one in the north of England, had accommodation for no more than 600. Referring to returns recently published by the Lunacy Commissioners and by the Local Government Board, he mentioned that in England and Wales there were 385 children under 18 years of age returned as idiots or imbeciles in lunatic asylums, and 485 in the workhouses in addition. Neither the asylum nor the workhouse was a fit place for an idiot child. He urged upon the provincial authorities, and especially the Lancashire Asylum Board, the desirability of following the lead of the metropolis in providing suitable training and care for the imbecile class. He mentioned several remarkable cases of improvement in discharged patients, amongst whom one was receiving £1 a week at the trade which he had learned at the asylum, and two others were serving with credit in the army. There were, moreover, numerous cases in which notable improvement in habits and conduct had been effected by training, very much to the relief of the parents when their children returned home.

We are glad to see that this asylum, which though fundamentally a charity, receives a certain proportion of patients paid for either by their friends or by Poor-law guardians, continues to be well supported, committees of ladies in various parts of the district tending valuable aid in the collection of subscriptions. During the year reported on as much as £19,048 s. 11d. had been received from all sources on maintenance account, and the inclusive weekly cost of maintenance had been at the rate of 12s. 11d. per head.

DERBYSHIRE COUNTY LUNATIC ASYLUM.

THE forty-third annual report of this institution deals with the events of 1894. Here, as in so many other county asylums, the great cry is for more room, as the asylum is overcrowded. Fortunately the Committee have taken an enlightened view of the situation, and new buildings will relieve the pressure are well in hand. Meanwhile Dr. Murray Lindsay tells us that the congested condition of the asylum alluded to in the report for 1893 has continued during a considerable portion of last year, notwithstanding the removal of some chronic cases. He also pleads with some force for the provision of accommodation for private patients, and quotes the statement which has attended the admission of private patients in other county asylums. The admissions during the year were 151, the highest number recorded in any year since the asylum was opened forty-three years ago, and this large number would have been further increased if the asylum had been capable of receiving all the Derbyshire patients. Of the 109 patients discharged, 60 were recovered, being at the rate of 49.30 per cent. to the admissions. No fewer than 4 were discharged "not insane." The death-rate was 2.78 per cent. to the daily average number resident. Amongst the causes of death general paralysis heads the list. No inquest was deemed necessary. The Asylum Committee are to be congratulated upon having adopted a "pension scheme as the scale for guidance of the Visiting Committee." This has given great satisfaction to the staff, and the good example thus set should soon be followed in every public asylum in the Kingdom. Dr. Murray Lindsay, whose labour in the cause of pensions for asylum workers has been carried on unsparringly for some years, has now the satisfaction of seeing his labours crowned with success in the institution which he so ably superintends.

INDIA AND THE COLONIES.

INDIA.

THE P. M. O. MADRAS.—In reply to a query from the Madras Government as to whether it is intended to reserve the appointments of Personal Assistant to the P. M. O. Madras (Command) for officers of the Army Medical Staff, and whether there is any probability of an officer of the Indian Medical Service always holding the appointment of P. M. O. Madras (Command), the Government of India has stated that when the appointment of P. M. O. is held by an officer of the Indian Medical Service, the appointment of Personal Assistant should be held by an officer of the Army Medical Staff, and vice versa. As regards the appointment of P. M. O., it may be held by officers of either the Indian Medical Service or Army Medical Service. As the post of Personal Assistant is not an additional appointment, officers selected to hold these appointments must be taken from the authorized cadre.

SANITATION IN BANGALORE.—It has been the subject of local controversy for years back, but the Government of India, prompted by Mr. Leo Warner, late Resident acting on the advice of the Boundary Commission, have now taken the matter into their own hands. By way of combating the recent outbreak of cholera, a medical expert has been placed on special duty to enforce sanitary measures, and to draw up proposals for a reconstruction of the Municipal Sanitary Department, and that be found desirable, as says the *Press*, no doubt it will.

TYPHOID AT BANGALORE.—A Medical Staff writing to us in reference to typhoid fever in Bangalore, such as the following particulars. The water from the Ussor tank is pumped to the European barracks, bakery, and

to the European and three native hospitals. The Europeans only use this for drinking purposes, and some camps use it for cooking. The native hospitals (for this tank is the Bangalore bazaar, and the water is very bad. The drinking water for Europeans is carried daily from the Bangalore tank to the barracks and hospitals; it is there filtered and boiled. The water as it comes from the tank is of good quality, but very offensive in private bungalows, and there is no doubt that many of them use the Ussor tank water. It appears, also, that orders for the boiling of water at Bangalore were issued some time since, but according to the evidence forwarded to us, these orders appear to have been carried out very fitfully in many places or not at all. It is hoped that now attention has been called to the matter, steps will be taken to provide a pure water supply, and to make adequate filtering arrangements. The water in use appears to have been of an inferior quality, and it is probable to be quite different from the Pasteur water, which with no doubt being about a very different result. Our correspondent writes: Mr. Ernest Hart has not initiated the boiling of water, but he has, however, strengthened our hands, and I for one thank him.

THE CULTIVATION OF CHICKEN.—An interesting statistical table which has just been forwarded by Mr. G. G. G. on the subject of poultry for the past ten years points conclusively to its steady decline. In 1894 in Madras possessed some 4,200 acres, Bengal 3,200, Mysore 2,100, and Coorg 1,700, or a total of 14,400 acres. The figures, however, just to hand for 1894-95 show that the respective areas under cultivation now are: Madras 5,810, Bengal 2,608, Mysore 380, and Coorg only 15 acres, or a total of 8,798 acres.

THE SANITARY NEEDS OF INDIA.—The report of the Sanitary Commissioner of the Central Provinces of India for the year 1894 is a very interesting one. By the Chief Commissioner in his review as being deficient in information. He complains that it is hard, not to say impossible, to gather from it a comprehensive view of the whole scope and progress of sanitary work during the year. There is no information as to the condition of small capillaries or schools or other public institutions, the sanitary condition of towns, gaols, especially in the villages and hamlets, is discussed in a few lines. This is attributable to the inevitable change in the personnel of the appointment of Sanitary Commissioner.

CEYLON.

SANITATION IN 1894.—The Administration report recently submitted by Dr. Kinsey, Principal Medical Officer of Ceylon, for the year 1894, contains matter which demands the earnest attention of the Colonial Government. Three importations of cholera from India took place, but the spread of disease appears in each instance to have been arrested by prompt and effective preventive measures. But, however, small it was, of which 60 proved fatal, had occurred in the localities and communities to which infection had been introduced by boatmen and pilgrims. The fact that only 10 cases of small-pox, with 1 death, happened in the whole island during the year is a legitimate subject for congratulation. Deaths from malarial fever are un happily on the increase. How far this is due to greater activity in pushing irrigation works is a very serious question. The Governor of Ceylon, in his recent address to the Legislative Council, remarks that what is needed for the development of Ceylon is "first, irrigation; secondly, irrigation; and, lastly, irrigation." And it appears that Rs. 23,91,408 have been expended on irrigation works during the last five years. No doubt increased irrigation means more agriculture, more and cheaper food, and better drinking water, but the experience of India has unfortunately furnished sore and large proof that irrigation without adequate drainage means more fever and enhanced mortality. Drainage works must keep pace with irrigation, else increase of malarial disease is certain. There appears, also, to be a pressing need for dealing effectively with flood water in Ceylon. The island is visited with frequent rain storms, which cause the submergence of large tracts of country, and if the water is not speedily removed it stagnates and produces conditions eminently favourable to severe outbreaks of fever and dysentery. If irrigation is a prime condition of agricultural prosperity in Ceylon, drainage is undoubtedly a cardinal requisite of health.

MEDICAL ADMINISTRATION.—It is exceedingly Sir Arthur Elphinstone Harelock, G.C.M.G., Governor of Ceylon, in his opening address to the Legislative Council, made the following interesting observations on the progress which has taken place during the last twenty years in regard to arrangements for public medical relief: "The Medical Department of Ceylon has always occupied a prominent place in the administration of the country. Its operations have vastly extended during the last twenty years. In 1874 there were 10 hospitals and pavilions, and 14 dispensaries; in 1894 there were 108 hospitals and pavilions, and 140 dispensaries; in 1874 there were 14,000 persons treated in hospitals, and 2,000 in dispensaries; in 1894 the numbers respectively were 1,000,000 and 1,000,000. The expenditure on medical aid, which in 1874 amounted to Rs. 4,000, had risen in 1894 to Rs. 12,000,000. The expansion of the work of this department during the five years from 1890 to 1894 was probably more rapid than during any previous quinquennial period. The amount of public expenditure increased from Rs. 4,000 in 1890, to Rs. 12,000,000 in 1894. The system of European medical treatment is rapidly gaining the confidence of the native population. I am convinced that in no way do the poorer taxpayers of Ceylon get a better return for their money than for the benefit they derive from the Medical Department. I am strongly impressed with the belief that the medical aid given by the Government to the people constitutes more largely to the happiness of society than any other of the many blessings of British rule in this country."

THE latest statistics place the number of medical men in Paris at 2,923, of whom 52 are foreigners. From this it is calculated that there is 1 French doctor to every 1,000 French people in Paris, whereas there are nearly 3 foreign doctors to every 1,000 foreigners.

THE November number of *Science Progress* contains an interesting notice of the life and work of the late Professor Carl Ludwig, from the pen of Professor W. Stirling, of Owens College.

MEDICAL NEWS.
